The majority of these nomadic Arabs were Sabians, or Star-worshipers, before the adoption of Islam. History has preserved for us the names of several tribes who paid divine honors to single planets, or conspicuous fixed stars. No wonder that they should have fallen into such idolatry! The dust raised by the desert wind, which, as a rule, only blows during the day, and the heat of the sun compel them to pasture their herds and to undertake their hostile expeditions during the night. Leisure and[118] necessity bid them gain information by directing their gaze at the starry sky, which is presented to them in a splendor of which we in our northern regions can scarcely form any idea. Since, therefore, the aborigines must have noticed at an early period that the nearly regular succession of changes in their climate took place in conformity with the annually recurring phenomena of the fixed stars, they ascribed to the latter a divine power. Thus originated the worship of the stars; and this once established, no other motives were needed to induce them to devote their constant attention to the starry skies. One result of this was that they applied proper names to the most conspicuous stars and groups of stars which were borrowed partly from the animal world around them, partly from their simple household effects, partly from various qualities and circumstances which they noticed in the stars. One tribe selected one name; another, another; and so it came to pass that one star, or group of stars, frequently bears more than one name. When, on the other hand, stars no less bright bear no names at all, the probable reason is that only fragments of the astronomical nomenclature of the Arab nomads have come down to us.

After this terminology had been transmitted by oral tradition, and especially by folk-songs, for hundreds, perhaps thousands, of years in its original condition, it was combined into an entirely heterogeneous mass—that variegated mixture which we find in the works of Kazwini, Ulug Bekh, and others.

When the Arabs in their fanatic zeal for the spread[119] of Mohammed's doctrines had conquered a great part of Asia, Africa, and Europe, and established in the heart of the ancient world a mighty empire, they adopted from the Greeks, with whom they had now

come in contact, their astronomy among other sciences, and with it the Greek constellations and their method of distinguishing the stars according to their position in the figures.[15]

Their astronomers now generally discriminated between the two classes of names in attributing the one to the Arabs, the other to the astronomers.

Abdelrahman Sufi, in the preface to his work on the constellations, says there are two kinds of heavens to become acquainted with—that of the astronomers and that of the Arabs. In the work itself he first describes the constellations used by the astronomers, i. e., the Greek ones, and then the old constellations of the Arabs. Kazwini in every case mentions a genuine Arabic star-name when he speaks of the Arabic, which is the case with almost every constellation.

Our early astronomers had very false notions of this relation of the nomadic heavens of the ancient Arabs to the mythological one of the Greeks adopted by their descendants. Schickard, in his Astroscopium, says: “Instead of the Dragon the Arabs depict two wolves and five dromedaries.” He means the two jackals and the family of camels which the[120] nomads represented under the five stars on the head of the Dragon. The Arab astronomers drew the Greek dragon on their charts and globes just as we do. They only looked on the old jackals and camels as names for some of its stars. In Golius and Hyde we find a more correct view of the case. FOOTNOTES:

[15] Already in the ancient book of Job, whose hero has quite the characteristics of a Nomadic Emir, we find some astronomical terms whose analogy with the true Arabic star-names is unmistakable. See Job, ix. 9; xxxviii. 31, 32. ASTRONOMY WITHOUT A TELESCOPE.—J. E. Gore

It must be remembered that astronomy was studied ages before the invention of the telescope, and that the ancient astronomers gained, without any optical assistance, a considerable amount of knowledge respecting the heavenly bodies.

Let us first consider the stars visible to the naked eye. The number of these down to the sixth magnitude—about the faintest that average eyesight can see—is, for both hemispheres, about 6,000. The number, therefore, visible at one time from any given place is about 3,000. Possibly double this number might be seen by those gifted with exceptionally keen eyesight; but even this is a comparatively small number, scattered as it is over so large an area. Those who do not possess the power of effective enumeration estimate the number visible to the naked eye as considerably greater than is really the case. This is partly due to the irregular distribution of the lucid stars over the celestial vault, and partly to the effect which the aspect of the starry sky produces on the imagination; the fact of the stars increasing in number as they diminish in brightness inducing us to suspect[121] the presence of points of light which we do not actually see. An attempt to count those visible with certainty in any selected portion of the sky will, however, convince any intelligent person that the number, far from being large, is really very small, and that the idea, which some entertain, of a countless multitude is merely an optical illusion, and a popular fallacy which has no foundation in fact. Of course, the number visible in telescopes is very considerable. Perhaps with the largest telescopes 100,000,000 could be seen; but even this large number is very far from being “countless.” The present population of the earth is about 1,400,000,000, or about fourteen times the number of the visible stars!

The first thing to be done in studying the heavens with the naked eye is to learn the positions and names of the brighter stars; and from these the fainter ones may easily be identified by means of a star atlas. Those who study the stars in this way have probably a more intimate knowledge of the starry heavens than professional astronomers, who generally find the stars—at least the fainter ones—by referring to a catalogue of stars, and then setting their telescope to the place indicated by the figures given in the catalogue. Although the famous astronomer Sir William Herschel possessed several large telescopes, he also studied the stars with the naked eye, and it is related of this great observer that he could without hesitation identify any star he could see in this way by its name, letter, or number! Such an exhaustive knowledge of the heavens is, of course, very rare; but an acquaintance with all the brighter[122] stars can easily be acquired by any person of ordinary intelligence.

The “Plow,” or Great Bear,[16] is familiar to most people. This remarkable group of seven stars will be found very useful in identifying some of the brighter stars. The two stars furthest from the “tail” are called “pointers,” as they point nearly to the Pole Star, or star to which the axis of the earth nearly points. I say “nearly,” for the Pole Star is not exactly at the pole, but distant from it about three diameters of the moon. The northern of these stars is known to astronomers by the Greek letter Alpha and the southern as Beta. The others, following the order of the figure, are known by the letters Gamma, Delta (the faintest of the seven), Epsilon, Zeta, and Eta.[17] Now, if the curve formed by the three stars in the tail, Epsilon, Zeta, and Eta, is continued on, it will pass near a very bright star. This is Arcturus (Alpha of the constellation Boötes), one of the brightest stars visible. Again, if we draw an

imaginary line from Gamma to Beta, and produce it, it will pass near another bright star. This is Capella (Alpha of Auriga, “the Charioteer” referred to by Tennyson).

Again, if we draw a line from Delta to Beta, and produce it, it will pass near the tolerably bright stars, Castor and Pollux (Alpha and Beta of the constellation Gemini, or the Twins), the northern of[123] the two being Castor. Another line from Delta to Gamma produced will pass near a bright star called Regulus (Alpha of Leo, the Lion). Another line from Beta to Eta will pass near a group called Corona Borealis, or the Northern Crown. Photo of Orion Constellation of Orion, showing the Belt and Sword

On the opposite side of the Pole Star from the Plow, a group of five conspicuous stars will be found, forming a figure shaped somewhat like a W. This is Cassiopeia’s Chair. Commencing with the most westerly of the five, these stars are known as Beta, Alpha, Gamma, Delta, and Eta. Like the stars of the Plow, those of Cassiopeia’s Chair may be used to find other stars. For instance, a line drawn from Beta to Alpha passes close to a star known as Gamma in Andromeda; and the same line produced in the opposite direction will pass a little north of the bright star Vega (Alpha Lyræ), one of the brightest stars in the northern heavens. A line from Gamma to Alpha produced will pass through the well-known “Square of Pegasus.”

To the east of Vega lies Cygnus, or the Swan, a well-known northern constellation. It may be recognized by the long cross formed by its principal stars, Alpha, Beta, Gamma, Delta, and Epsilon; Alpha, or Deneb, being the most northern and brightest, and Beta the most southern and faintest of the five.

To the southeast of Cassiopeia’s Chair lies the constellation Perseus, distinguished by its well-known festoon, or curve, of stars. South of this lies the constellation Taurus or the Bull, which contains the well-known groups or clusters, the Pleiades and[124] the Hyades. The Pleiades form perhaps the most remarkable group of stars in the heavens, and are easily found, when above the horizon. To ordinary eyesight the cluster consists of six stars. Some persons gifted with exceptionally keen eyesight have, however, seen eleven or twelve. A map of the Pleiades made in the sixteenth century shows eleven stars very correctly. This was drawn, of course, from observations made with a measuring instrument, but without the aid of a telescope. The observer (I think it was Möstlin, Kepler’s tutor) must have possessed wonderfully sharp eyesight. The Hyades form a V-shaped figure, and contain the bright reddish star Aldebaran.

South of Taurus and Gemini will be found the splendid constellation of Orion, perhaps the most brilliant group of stars visible in either hemisphere. A remarkable quadrilateral figure is formed by its four stars, Betelgeuse (Alpha) and Gamma[18] on the north, and Rigel (Beta) and Kappa on the south. Of these Betelgeuse and Rigel are bright stars of the first magnitude. Betelgeuse is distinctly reddish and also slightly variable in its light. Rigel is a beautiful white star. In the middle of the quadrilateral are three stars of the second magnitude, nearly in a straight line, known as Delta, Epsilon, and Zeta, Delta being the northern of the three. These form Orion’s “belt.” South of these are three faint stars, also in a straight line, forming the “sword” of Orion. Surrounding the central star of the “sword” is “the[125] great nebula of Orion,” one of the finest objects in the heavens. It is barely visible to the naked eye, but may be seen with a good opera-glass.

To the southeast of Orion will be found Sirius, the brightest star in the heavens. It is the chief star of the constellation Canis Major, or the Great Dog, and has been well termed “the monarch of the skies,” from its great brilliancy.

The bright star Regulus, referred to above, is situated in a remarkable group of stars shaped like a sickle, and known as “the Sickle in Leo.” Regulus lies at the extremity of the handle. Leo is well placed for observation in April and May.

The famous group called the Southern Cross forms a conspicuous object in the southern heavens. It has formed a subject of interest since the earliest ages of antiquity. Its component stars, are, however, not so brilliant as some suppose, the two brightest being between the first and second magnitudes, the next of the second, and one between the third and fourth magnitudes. Near the Southern Cross are two bright stars known as Alpha[19] and Beta of the Centaur.

Among the stars are many objects known as “double stars.” These consist of two stars very close together, but which appear to the naked eye only as single stars. Some are triple, and even quadruple. Of these double stars there are now about 10,000 known to astronomers, but they are only visible with a telescope. Some, indeed, are so close that the highest powers of the very largest telescopes are necessary[126] to see them as anything but single stars. Of the naked-eye stars there are, however, some apparently so close that they present very much the appearance of real double stars as seen in a telescope. These, although not recognized by astronomers as double stars, have been termed “naked-eye doubles.” Houzeau found that the brighter the stars are the easier it is to separate them; and that for small stars, about 15′ of arc, or half the moon’s apparent diameter, is about the limit

below which the naked eye can not see a faint star double. Drawing of Great Bear Fig. 15.—Constellation of the Great Bear

Of the “naked-eye doubles,” perhaps the most remarkable is Mizar, the middle star in the “tail” of the Great Bear. Close to it is a small star, sometimes called “Jack on the Middle Horse.” It was known to the ancient astronomers as Alcor, or “the test,” as[127] it was then considered a test of excellent eyesight. Whether it has really brightened seems doubtful, but at present it is perhaps visible to ordinary eyesight. Some, however, fail to see it, while to others with keener vision it seems as plain as the proverbial “pike-staff.” The star Alpha Capricorni consists of two stars which, although closer than Mizar and Alcor, are more equal in brightness, and may be easily seen with the naked eye on a clear night. Nu Sagittarii may also be seen double in this way. Theta Tauri, in the Hyades, is another object which some eyes can see distinctly double; also Kappa Tauri, a little to the north of the Hyades; Omicron Cygni, a little to the west of Alpha Cygni (Deneb), is another example. On a very fine night two stars may be seen in Iota Orionis, the most southern star in the “sword.” Near Gamma Leonis, one of the brightest stars in the “sickle,” is a star of the sixth magnitude, which some can see without optical aid.

The most severe test is, however, Epsilon Lyræ, the northern of two small stars which form a little triangle with the brilliant Vega. This, to some eyes, appears double. The famous German astronomer Bessel is said to have seen it at thirteen years of age. To most people, however, it will perhaps appear only elongated. This is a very remarkable star, as each of the components is seen to be a close double when examined with a good telescope; and between the pairs are several fainter stars.

Among those interesting objects, the variable stars, are several which may be well observed without optical assistance. Of these may be mentioned Algol, of[128] which all the fluctuations of light may be easily observed with the naked eye; Mira Ceti, which may be well observed when at its brightest; Lambda Tauri, a variable star of the Algol type; Betelgeuse (Alpha Orionis), which is slightly variable; Zeta Geminorum, a fourth magnitude star, which varies about three-quarters of a magnitude in a period of about ten days; R. Hydræ, which is visible to the naked eye at maximum; Beta Lyræ, period about thirteen days; Eta Aquilæ, period about seven days; and Delta Cephei, which varies about one magnitude in a period of a little over five days. Of all these stars useful observations may be made without optical assistance of any sort.

Observations, and even discoveries, of new or “temporary” stars may also be made with the naked eye. This occurred in the case of the “temporary” stars of 1572, 1604, 1670, 1866, and 1870, but, of course, these were bright objects at the time of their discovery. Hind’s “new star” of 1848 in Ophiuchus was, however, only of the fifth magnitude when it appeared, and it might have escaped detection with the naked eye. A star of this magnitude might, however, be easily detected by an observer who is familiar with the principal stars of a constellation.

The Milky Way may, perhaps, be better seen with the naked eye than with any instrument, although an opera-glass brings out well, in some places, its more delicate details. A mere passing glance might lead a casual observer to suppose that the Galaxy stretched as a band of nearly uniform brightness across the heavens. But good eyesight, careful attention, and[129] a clear sky will soon disclose numerous details previously unsuspected; streams and rays of different brightness, intersected by rifts of darkness, and interspersed with spots and channels of comparatively starless spaces. An excellent drawing of the Milky Way—the result of five years’ observations with the naked eye alone—has recently been completed by Dr. Otto Boeddicker at Lord Rosse’s observatory in Ireland. This beautiful picture is exquisitely drawn, and shows a wonderful amount of detail. A writer in the Saturday Review of November 30, 1889, says: “His maps are in many respects a completely new disclosure. Features barely suspected before come out in them as evident and persistent; every previous representation appears, by comparison, structureless.” This shows what can be done with the naked eye in the study of this wonderful zone.

Among the nebulæ and clusters there are not many objects visible to the naked eye. A hazy appearance about the middle star in Orion’s “sword” indicates the presence of the “great Nebula,” one of the finest objects in the heavens. The “great Nebula in Andromeda,” aptly termed “the Queen of the Nebulæ,” is distinctly visible to the naked eye on a very clear night. It lies near the four and a half magnitude star, Nu Andromedæ (a few degrees north of Beta Andromedæ), and may be well seen in the early evening hours in the month of January, when it is high in the sky. It somewhat resembles a small comet. This nebula was known long before the invention of the telescope, and it was described by one of the earlier astronomers as resembling “a[130] candle shining through horn,” a not inapt description.

Of star clusters visible without optical aid may be mentioned the double cluster Chi Persei, which appears to the eye as a luminous spot in the Milky Way; the cluster known as 35 Messier, a little north of Eta Geminorum, just visible to the naked eye on a very clear night; and there are others in the Southern Hemisphere, notably the globular cluster known as Omega in the Centaur, which shines

as a hazy star of the fourth magnitude. Among the clusters may perhaps be included the Præsepe, or the “Beehive,” in Cancer, which has a nebulous appearance to the naked eye.

Coming now to the Solar System, the sun and moon, of course, first attract attention. Cases of sun-spots visible to the naked eye are recorded, but, of course, spots of such enormous size are of rare occurrence. Of lunar detail little can be seen without a telescope of some sort, but the larger markings are sufficiently distinct to good eyesight to convince the observer that they do not alter perceptibly, thus showing clearly that the moon always turns the same side to the earth.

Of the planets, nothing of their appearance in the telescope can, of course, be seen with the naked eye, but it is easy to identify the brighter planets. Mercury, owing to its proximity to the sun, is rarely visible in Europe and North America, but when favorably situated, it may sometimes be detected near the sun shortly after sunset or a little before sunrise. Notwithstanding the difficulty of seeing it, it was[131] well known to the ancients, an observation of the planet dating back to 264 B. C. It is easier, however, to see in more southern latitudes, and I have frequently observed it as bright as a star of the first magnitude in the clear air of the Punjab sky. I have also seen it on several occasions in Ireland, and the Rev. S. S. Johnson, F.R.A.S., tells me he has seen it with the naked eye no less than one hundred times in the south of England. The brilliant planet Venus can hardly be mistaken when seen in the morning or evening sky. When at its brightest it considerably exceeds Jupiter and Mars, and far surpasses Sirius, the brightest star in the heavens.

If a very bright planet is seen rising at sunset, it can not be Venus, which is never seen beyond a limited distance from the sun. The observer may, therefore, conclude with certainty that the planet is either Jupiter or Mars. The latter, which occasionally rivals Jupiter in brilliancy, may be easily distinguished from the “giant planet” by its distinctly reddish color. Saturn shines with a yellowish light, and is never so bright as Mars or Jupiter when at their brightest. The planet Uranus is just visible to the naked eye, and may be found without optical assistance when its position is accurately known.

Some observers think that they can see the crescent of Venus with the naked eye when the planet is in that phase, but this seems very doubtful. Cases have been recorded of one or two satellites of Jupiter having been seen with the unaided eyesight, but few are gifted with such keen vision.

Occultations of bright stars may be well seen with[132] the naked eye, especially when they pass behind the moon’s dark limb, and as the disappearance of a star is practically instantaneous, really valuable observations may be made without a telescope, by merely noting the exact time at which the star vanishes.

Most of the comets discovered by astronomers are small and faint, and only visible in good telescopes. At intervals, however, a brilliant visitor appears on the scene, and its path among the stars may be watched from night to night with the naked eye. Before the invention of the telescope, bright comets were watched in this way, and their course recorded so carefully that it has been found possible to calculate their orbits with some approach to accuracy. In these days of large telescopes and instruments of almost mathematical precision, such a method of observation is, of course, superseded; but we may still watch the movements of a bright comet with interest, and note its apparent path across the sky with pleasure and profit. Shooting stars and fire-balls may be best observed with the naked eye, and the excellent work done in this way by Mr. W. F. Denning, F.R.A.S., should encourage others to take up this interesting branch of astronomy.

Another object which may be well seen with the naked eye—indeed, it may best be observed in this way—is the Zodiacal Light. This is a lenticular or cone-shaped beam of light, which makes its appearance at certain times of the year, above the eastern horizon before the dawn, and above the western horizon after sunset, when the sky is clear and the moon absent. In the tropics it is much more easily[133] seen, the twilight being shorter, and I have often observed it in India shining with great brilliancy.

From the above sketch my readers will see how much may be learned of astronomy without optical assistance of any kind, and I hope that those who do not possess a telescope will use their eyes instead, and thus gain some knowledge of the wonders and beauties of the starry heavens. The knowledge thus gained will stimulate their curiosity and will give them keener interest in reading books which describe the still greater wonders revealed by the telescope. FOOTNOTES:

[19] This is the nearest star to the earth.—E. S. THE MILKY WAY.—Richard A. Proctor

To those who rightly appreciate its meaning the Milky Way is the most magnificent of all astronomical phenomena. However opinions may vary as to the configuration of the star-streams composing this object, no doubt now exists among astronomers that the Milky Way consists really of suns, some doubtless falling short of our own sun in brilliancy, but many probably surpassing it. Around these suns, we may fairly conceive, there revolve systems of dependent orbs, each supporting its myriads of living creatures. We have afforded to us a noble theme for contemplation in the consideration of the endless diversities of structure, and of arrangement, which must prevail throughout this immensity of systems.

The Galaxy traverses the constellation Cassiopeia. Thence it throws off a branch toward Alpha Persei[134] (Mirfak), prolonged faintly toward the Pleiades. The main stream, here faint, passes on through Auriga, between the feet of Gemini and the Bull's horns, over Orion's club to the neck of Monoceros. Thence, growing gradually brighter, the stream passes over the head of Canis Major, in a uniform stream, until it enters the prow of Argo, where it subdivides. One stream continues to Gamma Argus, the other diffuses itself broadly, forming a fan-like expanse of interlacing branches, which terminate abruptly on a line through Lambda and Gamma Argus. Here there is a gap beyond which the Milky Way commences in a similar fan-shaped grouping, converging on the brilliant (and in other respects remarkable) star Eta Argus. Thence, it enters the Cross by a narrow neck, and then directly expands into a broad, bright mass, extending almost to Alpha Centauri. Within this mass is a singular cavity known as the Coal-Sack. At Alpha Centauri the Milky Way again subdivides, a branch running off at an angle of 20°, and losing itself in a narrow streamlet. The main stream increases in breadth, until, "making an abrupt elbow," it subdivides into one continuous but irregular stream, and a complicated system of interlacing streams covering the region around the tail and following claw of Scorpio. A wide interval separates this part of the Galaxy from the great branch on the northern side, terminating close on Beta Ophiuchi.

The main stream, after exhibiting several very remarkable condensations, passes through Aquila, Sagitta, and Vulpecula to Cygnus. In Cygnus there is a "confused and patchy" region marked by a broad[135] vacancy, not unlike the Coal-Sack. From this region there is thrown off the offset to Beta Ophiuchi, already mentioned; the main stream is continued to Cassiopeia. Star map Fig. 16.—The Midnight Sky, with Milky Way

There only remains to be noticed "a considerable offset or protuberant appendage," thrown from the head of Cepheus directly toward the pole. Galileo was the first to prove, though earlier astronomers had entertained the notion, that the Milky Way was composed of a vast number of stars crowded closely together. But no attempt was made to offer a theory of its structure until, in 1754 Thomas[136] Wright, in his Theory of the Universe, propounded views closely according with those entertained later by Sir W. Herschel. Wright, having examined a portion of the Galaxy with a reflecting telescope, only one foot in focal length, came to the conclusion that our sun is in the midst of a vast stratum of stars; that it is when we look along the direction in which this stratum extends that we see the zone of light constituting the Milky Way; and that as the line of sight is inclined at a greater and greater angle to the mean plane of the stratum, the apparent density of the star-grouping gradually diminishes.

But it is to Sir W. Herschel, and the supplementary labors of Sir J. Herschel, that we owe the more definite views now commonly entertained respecting the Via Lactea. The elder Herschel, whose nobly speculative views of nature were accompanied by practical common-sense, and a wonderful power of patient observation, applied to the heavens his celebrated method of gauging. He assumed as a first principle, to be modified by the results of observation, that there is a tolerable uniformity in the distribution of stars through space. Directing his twenty-foot reflector successively toward different parts of the heavens, he counted the number of stars which were visible at any single view. The field of view of this reflector was fifteen minutes in diameter, so that the portion of the sky included in any one view was less than one-fourth of that covered by the moon. He found the number of stars visible in different parts of the heavens in a field of view of this size to be very variable. Sometimes there were but two[137] or three stars in the field;[20] indeed, on one occasion he counted only three stars in four fields. In other parts of the heavens the whole field was crowded with stars. In the richer parts of the Galaxy as many as four hundred or five hundred stars would be visible at once, and on one occasion he saw as many as five hundred and eighty-eight. He calculated that in one-quarter of an hour 116,000 stars traversed the field of his telescope, when the richest part of the Galaxy was under observation. Now, on the assumption above named, the number of stars visible when the telescope was pointed in any given direction was a criterion of the depth of the bed of stars in that direction. Thus, by combining a large number of observations, a conception—rough, indeed, but instructive—might be formed of the figure of that stratum of stars within which our sun is situated.

Sir J. Herschel, during his residence at the Cape of Good Hope, carried out an extensive series of observations of the southern heavens. Applying his father's methods of gauging with a telescope of equal power, he obtained a result agreeing, in a most remarkable manner, with those obtained by Sir William Herschel. It appeared, however, that the Southern Hemisphere is somewhat richer in stars than the Northern—a result which has been accepted as indicating that our system is probably somewhat nearer the southern than the northern part of the galactic nebula. Moreover, Sir J. Herschel was led to believe that the sidereal system forms a cloven flat ring rather than a disk.

[138]

I think no one who has attentively examined the glories of Orion, the richly jeweled Taurus, the singular festoon of stars in Perseus, and the closely set stars of Cassiopeia, but must have felt that the association of splendor along this streak of the heavens is not wholly accidental. The stars here seem to form a system, and a system which one can hardly conceive to be wholly unconnected with the neighboring stream of the Milky Way. But in the southern portion the arrangement is yet more remarkable and significant. From Scorpio, over the feet of the Centaur, over the keel of Argo, to Canis Major, there is a clustering of brilliant stars, which it seems wholly impossible not to connect with the background of nebulous light. It is noteworthy, also, that this stream of stars merges into the stream commencing with the group of Orion, already noticed. Nor is this all. It is impossible not to be struck by the marked absence of bright stars in the region of the heavens between Algol, Crux, and Corvus. One has the impression that the stars have been attracted toward the region of the stream indicated, so as to leave this space comparatively bare.

Now, this last circumstance would appear less remarkable if the paucity of stars here noticed were common also in parts of the heavens far removed from the Milky Way. But this is not the case. Beyond this very region, which we find so bare of stars, we come to a region in which stars are clustered in considerable density, a region including Crater, Corvus, and Virgo, with the conspicuous stars Algores, Alkes, and Spica. But what is very remarkable,[139] while we can trace a connection between the stream of bright stars over the Milky Way and the stream of nebulous light in the background, it is obvious that the two streams are not absolutely coincident in direction.

The stream lies on one side of the Milky Way near Scorpio, crosses it in the neighborhood of Crux, and passes to the other side along Canis Major, Orion, and Taurus. Does the stream return to the Milky Way? It seems to me that there is clear evidence of a separation near Aldebaran, one branch curving through Auriga, Perseus, and Cassiopeia, the other proceeding (more nearly in the direction originally observed) through Aries (throwing out an outlier along the band of Pisces), over the Square of Pegasus, and along the streams which the ancients compared to water from the urn of Aquarius (but which in our modern maps are divided between Aquarius and Grus). The stream-formation here is very marked, as is evident from the phenomenon having attracted the notice of astronomers so long ago. But modern travels have brought within our ken the continuation of the stream over Toucan, Hydrus, and Reticulum (the two latter names being doubtless suggested by the convolutions of the stream in this neighborhood). Here the stream seems to end in a sort of double loop, and it is not a little remarkable that the Nubecula Major lies within one loop, the Nubecula Minor within the other. It is also noteworthy that from the foot of Orion there is another remarkable stream of stars, recognized by the ancients under the name of the River Eridanus, which[140] proceeds in a sinuous course toward this same region of the Nubeculæ.

Having thus met with evidence—striking at least, if not decisive—of a tendency to aggregation into streams, let us consider if, in any other parts of the heavens, similar traces may not be observable. We traced a stream from Scorpio toward Orion, and so round in a spiral to the Nubeculæ. Let us now return to Scorpio, and trace the stream (if any appear) in the contrary direction. Now, although over the Northern Hemisphere star-streams are not nearly so marked as over the Southern, yet there appears a decided indication of stream-formation along Serpens and Corona over the group on the left hand of Boötes to the Great Bear. A branch of this stream, starting from Corona, traverses the body of Boötes, Berenice's Hair, the Sickle in Leo, the Beehive in Cancer, passing over Castor and Pollux in Gemini, toward Capella. A branch from the feet of Gemini passes over Canis Minor, along Hydra (so named doubtless from the obvious tendency to stream-formation along the length of this constellation), and so to the right claw of Scorpio.

One other remarkable congeries of stars is to be mentioned. From the northern part of the Milky Way there will be noticed a projection toward the North Pole from the head of Cepheus. This projection seems to merge itself in a complex convolution of stars, forming the ancient constellation Draco, which doubtless included the ancient (but probably less ancient) constellation Ursa Minor. After following the convolutions of Draco, we reach the[141] bright stars Alwaid and Etanin (Beta and Gamma) of this constellation, and thence the stream passes to Lyra, where it seems to divide into two, one passing through Hercules, the other along Aquila,

curving into the remarkable group Delphinus.

The streams here considered include every conspicuous star in the heavens. But the question will at once suggest itself, whether we have not been following a merely fanciful scheme, whether all these apparent streams might not very well be supposed to result from mere accident. Now, from experiments I have made, I am inclined to believe that in any chance distribution of points over a surface, the chance against the occurrence of a single stream as marked as that which lies (in part) along the back of Grus, or as the curved stream of bright stars along Scorpio, is very great indeed; I am certain that the occurrence of many such streams is altogether improbable. And wherever one observes a tendency to stream-formation in objects apparently distributed wholly by chance, one is led to suspect, and thence often to detect, the operation of law. I will take an illustration, very homely perhaps, but which will serve admirably to explain my meaning. In soapy water, left in a basin after washing, there will often be noticed a tendency to the formation of spiral whorls on the surface. In other cases there may be no definite spirality, but still a tendency to stream-formation. Now, in this case, it is easy to see that the curved bottom of the basin has assisted to generate streams in the water, either circulating in one direction or opposing and modifying each other's effects,[142] according to the accidental character of the disturbance given to the water in the process of washing.[21] Here, of course, there can be no doubt of the cause of the observed phenomena; and I believe that in every case in which even a single marked stream is seen in any congeries of spots or points, a little consideration will suggest a regulating cause to which the peculiarity may be referred.

It is hardly necessary to say that, if the stream-formation I have indicated is considered to be really referable to systematic distribution, the theory of a stratum of stars distributed with any approach to uniformity, either as respects magnitude or distance, must be abandoned. It seems to me to be also quite clear that the immense extent of the Galaxy, as compared with the distances of the lucid stars from us, could no longer be maintained. On this last point we have other evidence, which I will briefly consider.

First, there is the evidence afforded by clusterings in the Milky Way. I will select one which is well known to every telescopist, namely, the magnificent cluster on the sword-hand of Perseus. No doubt can be entertained that this cluster belongs to the galactic system, that is, that it is not an external cluster: the evidence from the configuration of the spot and from the position it occupies is conclusive[143] on this point. Now, within this spot, which shows no stars to the naked eye, a telescope of moderate power reveals a multitude of brilliant stars, the brightest of which are of about the seventh magnitude. Around these there still appears a milky unresolved light. If a telescope of higher power be applied, more stars are seen, and around these there still remains a nebulous light. Increase power until the whole field blazes with almost unbearable light, yet still there remains an unresolved background. "The illustrious Herschel," says Professor Nichol, "penetrated, on one occasion, into this spot, until he found himself among depths whose light could not have reached him in much less than 4,000 years; no marvel that he withdrew from the pursuit, conceiving that such abysses must be endless." It is precisely this view that I wish to controvert. And I think it is no difficult matter to show at least a probability against the supposition that the milky light in the spot is removed at a vast distance behind the stars of the seventh magnitude seen in the same field.

The supposition amounts, in fact, to the highly improbable view that we are looking here at a range of stars extending in a cylindrical stratum directly from the eye—a stratum whose section is so very minute in comparison with its breadth that, whereas the whole field within which the spot is included is but small, the distance separating the nearest parts of the group from the furthest is equivalent to the immense distance supposed to separate the sphere of seventh magnitude stars from the extreme limits of our Galaxy. And the great improbability of this[144] view is yet further increased when it is observed that within this spot there is to be seen a very marked tendency to the formation of minor streams, around which the milky light seems to cling. It seems, therefore, wholly improbable that the cluster really has that indefinite longitudinal extension suggested by Professor Nichol. In fact, it becomes practically certain that the milky light comes from orbs really smaller than the seventh magnitude stars in the same field, and clustering round these stars in reality as well as in appearance.

The observations applied to this spot may be extended to all clusters of globular form; and where a cluster is not globular in form, but exhibits, on examination, either (1) any tendency within its bounds to stream-formation, or (2) a uniform increase in density as we proceed from any part of the circumference toward the centre, it appears wholly inconceivable that the apparent cluster is not really a cluster, but a long range of stars extending to an enormous distance directly from the eye of the observer. When, in such a case, many stars of the higher magnitudes appear within the cluster, we seem compelled to admit the probability that they belong to it; and, in any case, we can not assign to the furthest parts of the cluster a distance greatly exceeding (proportionally) that of the nearest parts.

Of a like character is the evidence afforded by narrow streams and necks within the Galaxy itself. If we consider the convolutions over Scorpio, it will seem highly improbable that in each of these we see, not a real convolution or stream, but the edge of a[145] roll of stars. For instance, if a spiral roll of paper be viewed from any point taken at random, the chances are thousands to one against its appearing as a spiral curve, and, of course, the chance against several such rolls so appearing is very much greater. The fact that we are assumed to be not very far from the supposed mean plane of the Milky Way would partly remove the difficulty here considered, if it were not that the thickness and extent of the stratum, as compared with the distances of the lucid stars, must necessarily be supposed very great, on the assumption of any approach to uniformity of distribution.

Evidence pointing the same way is afforded by circular apertures in the Galaxy, or indeed by apertures of other forms. Another peculiarity of these cavities is also noticeable; whereas on the borders of every one there are many lucid stars, or in some cases two or three very bright stars, within the cavity there is a marked paucity of stars. This phenomenon seems to indicate a much closer connection between the brighter stars and the milky light beyond than is supposed on the stratum theory. One can hardly conceive the phenomenon to be wholly accidental.

There are some other points on which I fain would dwell, but space will not permit me. I will merely note that there are peculiarities in the distribution of red double and multiple stars, in the position in which temporary stars have made their appearance, and in the distribution of nebulæ, which seem very worthy of notice.

One point, however, immediately connected with my subject remains to be mentioned. I have traced[146] streams of stars more conspicuous than those forming the Milky Way. We have also evidence of streams of light yet more delicate and evanescent than the light of our own Galaxy. In Sir John Herschel's great work on the southern skies, he notes the frequent recurrence of "an exceedingly delicate and uniform dotting, or stippling, of the field of view by points of light too small to admit of any one being steadily or fully examined, and too numerous for counting, were it possible so to view them." In thirty-seven places he detected this remarkable and significant phenomenon; a phenomenon so faint that he says, "The idea of illusion has continually arisen subsequently"; an idea well befitting the modesty of the philosophic observer, but which those who appreciate Sir John Herschel's skill as an observer will be very unwilling to accept. As Professor Nichol remarks, "It is enough to read from Herschel's notebook—'I feel satisfied the stippling is no illusion, for its dark mottling moves with the stars as I move the tube to and fro'—to feel convinced that the phenomenon is real." Now a remarkable fact connected with those observations is, that when Sir J. Herschel marked down in a star-chart the places in which he had detected this nebulous appearance, he found that, "with the exception of three which appeared outlying and disconnected, they formed several distinct but continuous streams."

[147] FOOTNOTES:

[20] Field means the actual space covered by the lens.—E. S.

[21] Sometimes a singular regularity of curvature is noticed, and a spiral is formed closely resembling in configuration some of the great spiral nebulæ, as drawn by Lord Rosse, so that one is tempted to see in the centrifugal tendency of the disturbed water, and the centripetal effects caused by reflection from the basin's surface, causes which may in some sense illustrate the laws operating in wider domains of space. THE MAGELLANIC CLOUDS—ZODIACAL LIGHT—STAR GROUPS.—Amédée Guillemin

When we look on the region of the celestial vault which surrounds the South Pole, we can not help being struck with the contrast presented by the small quantity of stars which it contains, with the brilliant zone which borders the Milky Way, from Orion and Argo to the Centaur, passing by the Southern Cross. One solitary star of the first magnitude, Achernar, more distant from the pole than are the beautiful stars of the Centaur and of the Cross, shines in this part of the sky.

But even this circumstance renders the singular aspect of the two nebulous spots, which seem two detached pieces of the great galactic zone, still more striking. These half-stellar, half-nebulous systems, unequal in magnitude and brightness, but easily seen with the naked eye on a clear, moonless night, are situated, one, the larger and more brilliant, between the pole and Canopus, in the constellation of Doradus; the other, the smaller and less brilliant, ordinarily visible during the full moon, in Hydrus, between Achernar and the pole.

Both are known by astronomers and navigators under the name of "Cape Clouds," or again, "Magellanic Clouds." And, to distinguish them, we have again the Great Cloud (Nebecula Major) and the Small Cloud (Nebecula Minor).

The Clouds of Magellan are distinguished from[148] all other nebulæ by their great apparent dimensions, and by their physical structure; this last character distinguishes them from most of the branches and offshoots of the Milky Way, with which, we may also

add, they do not appear connected in any way.

The Great Cloud extends over a space which embraces not less than forty-two square degrees—about two hundred times the apparent surface of the lunar disk. The Small Cloud occupies in extent four times less than the other; according to Humboldt, it is surrounded “with a kind of desert,” where, it is true, shines the magnificent stellar cluster of Toucan. If the exterior aspect of these two remarkable nebulæ, and their situation in a celestial region poor in stars, give to the southern sky a peculiar appearance, their real structure makes them one of the wonders of the heavens.

In the Great Cloud, Herschel has counted 582 single stars, among which one only is of the fifth magnitude; six others are of the order immediately inferior, and would doubtless be visible to the naked eye if their light were not effaced by the general glare.

In the Small Cloud, the single stars are proportionally more numerous, since 200 have been counted, among which three are of the sixth magnitude, while it only includes thirty-seven of the nebulæ and seven star-clusters. These immense aggregations, the elements of which are themselves swarms of suns, remind us of the largest, in appearance at least, of all the clusters which the eye contemplates in the depths of the sky—the Milky Way.

[149]

In the evenings, about the time of the vernal equinox—in March and April, when in our climate the twilight is of short duration—if we examine the horizon toward the west, a little after sunset, we may perceive a faint light that rises in the form of a cone among the starry constellations.

This is what astronomers call the Zodiacal Light. Those unfamiliar with it, or little accustomed to the ordinary aspect of the sky, might confuse the glimmering either with the Milky Way or with the ordinary twilight, or even with an aurora. But, with a little attention, it is impossible to mistake it.

The triangular form of this luminous cone, its elevation and its inclined position to the horizon, make it a thing apart, and one eminently deserving particular mention.

As the days lengthen, and with them the duration of twilight, the Zodiacal Light disappears; it becomes invisible, at least in our climate. But it may again be seen in the morning, in the east, about the time of the autumnal equinox, in September and October, when the dawn has an equally short duration—again, however, to disappear during the period of long nights and long twilights.

It is needless to add that the sky must be clear and the night moonless for observations of the Zodiacal Light to be possible.

Among the explanations that have been given, the most probable one is that which likens the Zodiacal Light to a flattened nebulous ring surrounding the sun at some distance. It is to be remarked that the direction of the axis of the cone, or of the pyramid,[150] prolonged below the horizon, always passes through the sun.

It was believed at first that this direction precisely coincided with the solar equator; but it seems more certain that it coincides with the plane of the earth’s orbit, or the ecliptic.

Now, what is the nature of this luminous mass? Must it be considered as a zone of vapors thrown off by the sun, when in the process of consolidation, when our central star passed from a nebulous state to that of a condensed fluid sphere? This was the opinion of Laplace.

Another hypothesis, also connected with the first, is that the Zodiacal Light is formed of myriads of solid particles, analogous to the aerolites, possessing a general movement, but traveling separately around the focus of our solar world. The light of the ring would be thus produced by the accumulation of this multitude of brilliant points, reflecting toward us the light borrowed by each of them from the sun.

This explanation accounts for the intensity of the Zodiacal Light at different epochs; it would suffice to admit that the condensation of the particles or the density of the ring is not the same throughout its extent, and that its movement of circulation round the sun presents successively different parts to the earth. In this case, it becomes a question whether this lenticular ring of matter is distinct from the zone of aerolites.

Lastly, some astronomers regard the Zodiacal Light as a vaporous ring which belongs to the earth, surrounding it at some distance. But this is[151] an opinion which appears somewhat wild, and is utterly at variance with observation.

Are the stars that are visible to the naked eye spread orderless on the celestial vault? or is there not between those apparently most closely connected some real or physical connection which requires us to rank them in natural groups?

These questions have been already partly solved by what is known of the double and multiple star systems. Soon, exploring the regions of the sky visible by means of the telescope, we shall have to pass in review a multitude of stellar associations, in which suns are found so compact and so numerous, and the form of the groups so regular, that it is impossible to deny their reciprocal dependence.

But long before the discovery of these islands, these archipelagos as worlds, scattered with such astonishing profusion over the infinite, the naked eye had already distinguished a certain number of groups, the stars composing which were so near together that it was impossible to doubt their physical connection.

Such, for example, is the group of the Pleiades. Such, again, are the groups known under the names of the Hyades, of Præsepe, and of Berenice's Hair. All are visible to the naked eye, and good eyes distinguish without difficulty the principal stars of the first-named groups. The Pleiades are situated in the constellation of the Bull, which we can distinguish so easily to the northwest of Orion and Aldebaran.

Of about eighty stars which form the group of the Pleiades, six are visible without the help of telescopes.[152] Formerly, the Latin poet tells us, seven were counted, which may be held to prove that one of them is variable, and has diminished in brightness, or else has disappeared.

The most brilliant, Alcyone, is of the third magnitude; Electra and Atlas are of the fourth; Merope, Maïa, and Taygete of the fifth. Three others again have received particular names, although they are below the limit of ordinary vision; these are Pleione, Celeno, and Asterope, from the sixth to the eighth magnitude. All the others are only visible by the aid of a telescope; but with an ordinary glass it is possible to distinguish a large number. The Pleiades are known under the name of the Hen-coop, doubtless because Alcyone appears in the group as a hen surrounded with her chickens.

The Hyades, which are near the Pleiades, form a less numerous and more scattered group. The bright light of Aldebaran, which is, as is known, of the first magnitude, renders them more difficult to distinguish with the naked eye.

They appear in the rainy season. Hence their name of Hyades, from the Greek word which signifies to rain.

The connection of the stars which compose this group is not so striking as in the case of the Pleiades. Nevertheless, it seems difficult to admit that they are quite independent of each other's attraction. In examining the position of these two groups in the vicinity of the Milky Way, and observing that both are situated in the prolongation of a branch of the great zone, we are almost entitled to consider them as two[153] clusters of stars, belonging to the immense stellar stratum which surrounds us, and in the midst of which the sun himself is placed.

In Berenice's Hair, most of the stars are visible to the naked eye, and are perfectly distinguished in the sky, a little to the east of the Lion. No very brilliant star in the vicinity inconveniences the eye by effacing their light.

The next group is situated in the Crab, and is known under the name of Præsepe: it is visible to the unassisted sight; but it is impossible to distinguish the separate stars without the help of a telescope. Nevertheless, an instrument of moderate power easily separates them.

The groups which we have just described form a transition between the stars scattered over the celestial vault and the more condensed clusters, the undefined aspect of which caused them formerly to be designated under the general name of nebulæ.

Doubtless, if we could place ourselves in space, and contemplate from a sufficiently distant standpoint the whole of the stars which appear to us isolated, we should see them condensed into one or several distinct groups, analogous to those of the Pleiades; while, were we to penetrate into the midst of one of those compact clusters, we should see the stars of which it is formed separated and scattered over the celestial vault in such a way as to give it the aspect of our own heavens.

[154] THE NEBULÆ AND SWARMS OF SUNS.—J. E. Gore

We will now consider the nebulæ, properly so called, that is to say, objects which the spectroscope shows to consist of glowing gas. These are sometimes large and irregular in form, like the great nebula in the "Sword" of Orion, sometimes with spiral convolutions, and sometimes of a definite shape, like the planetary and annular nebulæ.

Of the large and irregular nebulæ, one of the most remarkable is that known as “the great nebula in Orion.” It surrounds the multiple star, Theta Orionis. It is a curious fact that it escaped the searching eye of Galileo, although he gave special attention to the constellation of Orion, for even with a good opera-glass a nebulous gleam is distinctly visible round the central star of the “Sword.” The nebula seems to have been discovered by Cysat, a Swiss astronomer, in the year 1618, and it was sketched by Huygens in 1656. It has been called the “fish-mouth” nebula, from the fancied resemblance of the centre portion to the mouth of a fish. A number of small stars are visible over the surface of the nebula, and at one time Lord Rosse thought it showed indications of resolution into stars when examined with his giant telescope; but this is now known to have been a mistake, for Dr. Huggins finds, with the spectroscope, that it consists of nothing but glowing gas.

The brightest line in the nebular spectrum—the[155] “chief nebular line,” as it is called—has not yet been identified with that of any terrestrial substance.

Mr. W. H. Pickering and Dr. Max Wolf have photographed another nebula surrounding the star Zeta Orionis—the southern star of the “Belt,” which seems to be connected with the nebula in the “Sword”; and Professor Barnard, using the “lens of a cheap oil lantern” of 1½ inches aperture and 3½ inches focal length, has photographed “an enormous curved nebulosity” stretching over nearly the whole of the constellation of Orion, and involving the “great nebula.”

Professor Keeler found, with the spectroscope, that the Orion nebula is apparently receding from the earth at the rate of nearly eleven miles a second, but this motion may be, in part at least, due to the sun’s motion in space in the opposite direction. Professor Pickering considers that the parallax of the nebula is probably not more than 0.″003, which corresponds to a thousand years’ journey for light!

In the southern constellation, Argo is a magnificent nebula, somewhat similar in appearance to the great nebula in Orion. It surrounds the famous variable star Eta Argûs. It is sometimes spoken of as the “keyhole” nebula, owing to a curious opening of that shape near its centre. It was carefully drawn by Sir John Herschel at the Cape of Good Hope in the years 1834-38. It lies in a very brilliant portion of the Milky Way, and Sir John Herschel thus describes it: “It is not easy for language to convey a full impression of the beauty and sublimity of the spectacle which the nebula offers as it enters the field[156] of view of a telescope, fixed in right ascension, by the diurnal motion, ushered in as it is by so glorious and innumerable a procession of stars, to which it forms a sort of climax, and in a part of the heavens otherwise full of interest,” and he adds: “In no part of its extent does this nebula show any appearance of resolvability into stars, being, in this respect, analogous to the nebula of Orion. It has, therefore, nothing in common with the Milky Way, on the ground of which we see it projected, and may therefore be, and not improbably is, placed at an immeasurable distance behind that stratum.” Sir John Herschel’s conclusion as to its physical constitution has been fully confirmed by the spectroscope, which shows it to consist of luminous gas. As in the Orion nebula, there are numerous stars scattered over it. Some of these may possibly have a physical connection with the nebula, while others may belong to the Milky Way. The nebula is of great extent, covering an apparent space about five times the area of the full moon, and its real dimensions must be enormous. It was photographed by Mr. Russell, director of the Sydney Observatory, in July, 1890, and the photograph shows that “one of the brightest and most conspicuous parts of the nebula”—the swan-shaped form near the centre of Herschel’s drawing—has “wholly disappeared,” and its place is now occupied by “a great, dark oval.” Mr. Russell first missed the vanished portion of the nebula in the year 1871, while examining it with a telescope of 11½ inches aperture, and the photograph now confirms the disappearance, which is very remarkable, and shows that changes are[157] actually in progress in these wonderful nebulæ, changes which may be detected after a comparatively short interval of time.

Smaller than the nebula in Argo, but somewhat similar in general appearance, is that known as 30 Doradus, which forms one of the numerous and diverse objects which together constitute the greater Magellanic Cloud. Sir John Herschel drew it carefully at the Cape of Good Hope, and describes it as “one of the most singular and extraordinary objects which the heavens present,” and he says “it is unique even in the system to which it belongs, there being no other object in either nubecula to which it bears the least resemblance.” It is sometimes called the “looped nebula,” from the curious openings it contains. One of these is somewhat similar to the “key-hole” opening in the Argo nebula. Near its centre is a small cluster of stars, and scattered over the nebula are many faint stars, of which Sir John Herschel gives a catalogue of 105, ranging from the ninth to the seventeenth magnitude. I do not know whether this nebula has been examined with the spectroscope, but its appearance would suggest that it is gaseous. It is remarkable as being the only object of its class which is found outside the zone of the Milky Way.

Among the nebulæ of irregular shape, although its spectrum is said to be not gaseous, may be mentioned that known as the “trifid nebula,” or 20 Messier. It lies closely north of the star 4 Sagittarii in a magnificent region of the heavens. In the drawing made by Sir

John Herschel at the Cape of[158] Good Hope, the principal portion consists of three masses of nebulous matter separated by dark “lanes” or “rifts.” Near the junction of the three “rifts” is a triple star. A beautiful drawing of this nebula has also been made by Trouvelot. It agrees fairly well with that of Sir John Herschel, but shows more detail.

Among other gaseous nebulæ may be mentioned that called by Sir John Herschel the “dumb-bell” nebula. It lies a little south of the sixth magnitude star 14 Vulpeculæ, and was discovered by Messier in 1779, while observing Bode’s comet of that year. In small telescopes it has the appearance of a dumb-bell, or hour-glass, but in larger telescopes the outline is filled in with fainter nebulous light, giving to the whole an elliptical form. Several faint stars have been seen in it, but these probably belong to the Milky Way, as Dr. Huggins finds the spectrum gaseous. Dr. Roberts has photographed it, and he thinks that “the nebula is probably a globular mass of nebular matter which is undergoing the process of condensation into stars, and the faint protrusions of nebulosity in the south following and north preceding ends are the projections of a broad ring of nebulosity which surrounds the globular mass. This ring, not being sufficiently dense to obscure the light of the central region of the globular mass, is dense enough to obscure those parts of it that are hidden by the increased thickness of the nebulosity, thus producing the ‘dumb-bell’ appearance. If these inferences are true, we may proceed yet a step, or a series of steps, further, and predict that the consummation[159] of the life-history of this nebula will be its reduction to a globular cluster of stars.”

Among the gaseous nebulæ may also be included those known as “annular nebulæ.” These are very rare objects, only a few being known in the whole heavens. The most remarkable is that known as 57 Messier, which lies between the stars Beta and Gamma Lyræ, south of the bright star Vega. It was discovered by Darquier, at Toulouse, in 1779, while following Bode’s comet of that year. Lord Rosse thought it resolvable into stars, and so did Chacornac and Secchi, but no stars are perceptible with the great American telescopes, and Dr. Huggins finds it to be gaseous. The central portion is not absolutely dark, but contains some faint nebulous light. Examined with the great telescope of the Lick Observatory, Professor Barnard finds that the opening of the ring is filled in with fainter light “about midway in brightness between the brightness of the ring and the darkness of the adjacent sky. The aperture was more nearly circular than the outer boundary of the nebula, so that the ends of the ring were thicker than the sides.” The entire nebula was of a milky color. A central star, noticed by some observers, was usually seen by Professor Barnard, but was never a conspicuous object. He found the extreme dimensions of the nebula about 81″ in length by about 59″ in width, or more than double the apparent area of Jupiter’s disk. It has been beautifully photographed by Dr. Roberts, and he says “the photograph shows the nebula and the interior of the ring more elliptical than the drawings and descriptions indicate;[160] and the star of the following side is nearer to the ring than the distance given. The nebulosity on the preceding and following ends of the ring protrudes a little, and is less dense than on the north and south sides. This probably suggested the filamentous appearance which Lord Rosse shows. Some photographs of the nebula have been taken between 1887 and 1891, and the central star is strongly shown on some of them, but on others it is scarcely visible, which points to the star being variable.” On a photograph taken by MM. Androyer and Montaugerand of the Toulouse Observatory, with an exposure of nine hours (in multiple exposures), about 4,800 stars are visible on and near the nebula in an area of three square degrees.

Another object of the annular class will be found a little to the southwest of the star Lambda Scorpii. It is thus described by Sir John Herschel: “A delicate, extremely faint, but perfectly well defined, annulus. The field crowded with stars, two of which are on the nebula. A beautiful, delicate ring of a faint, ghost-like appearance, about 40″ in diameter in a field of about 150 stars, eleven and twelve magnitude and under.”

Near the stars 44 and 51 Ophiuchi is another object of the annular class, which Sir John Herschel describes as “exactly round, pretty faint, 12″ diameter, well terminated, but a little cottony at the edge, and with a decided darkness in the middle, equal to a tenth magnitude star at the most. Few stars in the field, a beautiful specimen of the planetary annular class of nebula.”

[161]

The Planetary Nebulæ form an interesting class. They were so named by Sir William Herschel from their resemblance to the disks of the planets, but, of course, much fainter. They are generally of uniform brightness, without any nucleus or brighter part in the centre. There are numerous examples of this class, one of the most remarkable being that known as 97 Messier, which is situated about two degrees southeast of Beta Ursæ Majoris—the southern of the two “pointers” in the Plow. It is of considerable apparent size, and even supposing its distance to be not greater than that of 61 Cygni, its real dimensions must be enormous. Lord Rosse observed two openings in the centre with a star in each opening, and from this appearance he called it the “owl nebula.” One of the stars seems to have disappeared since 1850, and a photograph recently taken by Dr. Roberts confirms the disappearance.

Another fine object of the planetary class is one which lies close to the pole of the ecliptic. Webb saw it “like a considerable star out of focus.” Smyth found it pale blue in color. Dr. Huggins finds a gaseous spectrum, the first discovery of the kind made. Professor Holden, observing it with the great Lick telescope, finds its structure extraordinary. He says it “is apparently composed of rings overlying each other, and it is difficult to resist the conviction that these are arranged in space in the form of a true helix,” and he ranks it in a new class which he calls “helical nebulæ.”

A somewhat similar nebula lies a little to the west of the star Nu Aquarii. Secchi believed it to be in[162] reality a cluster of small stars, but Dr. Huggins finds its spectrum gaseous. A small nebula on each side gives it an appearance somewhat similar to the planet Saturn, with the rings seen edgewise. The great Lick telescope shows it as a wonderful object—“a central ring lies upon an oval of much fainter nebulosity.” Professor Holden says “the color is a pale blue,” and he compares the appearance of the central ring “to that of a footprint left in the wet sand on a sea beach.”

About two degrees south of the star Mu Hydræ is another planetary nebula, which Smyth describes as resembling the planet Jupiter in “size, equable light and color.” Webb saw it of “a steady, pale blue light,” and Sir John Herschel, at the Cape of Good Hope, speaks of its color as “a decided blue—at all events, a good sky-blue,” a color which seems characteristic of these curious objects. Although Sir William Herschel, with his large telescopes, failed to resolve it into stars, Secchi thought he saw it breaking up into stars with a “sparkling ring.” Dr. Huggins, however, finds the spectrum to be gaseous, so that the luminous points seen by Secchi could not have been stellar.

Sir John Herschel, in his Cape Observations, describes a planetary nebula which lies between the stars Pi Centauri and Delta Crucis. He says it is “perfectly round, very planetary, color fine blue ... very like Uranus, only about half as large again, and blue.... It is of the most decided independent blue color when in the field by itself, and with no lamplight and no bright star. About 10′ north of it[163] is an orange-colored star, eighth magnitude. When this is brought into view, the blue color of the nebula becomes intense ... color, a beautiful rich blue, between Prussian blue and verditer green.”

There are some rare objects called “nebulous stars.” The star Epsilon Orionis—the centre star of Orion’s Belt—is involved in a great nebulous atmosphere. The triple star Iota Orionis is surrounded by a nebulous haze. The star Beta in Canes Venatici is a 4½ magnitude star surrounded by a nebulous atmosphere.

The term elliptical nebulæ has been applied to those of an elliptical or elongated shape. This form is probably due in many cases to the effect of perspective, their real shape being circular, or nearly so. Perhaps the most remarkable object of this class is the well-known “nebula in Andromeda,” known to astronomers as 31 Messier. It can be just seen with the naked eye, on a clear moonless night, as a hazy spot of light near the star Nu Andromedæ, and it is curious that it is not mentioned by the ancients, although it must have been very visible to their keen eyesight in the clear Eastern skies. It was, however, certainly seen so far back as 905 A. D., and it is referred to as a familiar object by the Persian astronomer, Al-Sûfi, who wrote a description of the heavens about the middle of the Tenth Century. Tycho Brahe and Bayer failed to notice it, but Simon Marius saw it in December, 1612, and described it “as a light seen from a great distance through half-transparent horn plates.” It was also observed by Bullialdus, in 1664, while following the comet of[164] that year. It has frequently been mistaken for a comet by amateur observers in recent years. Closely northwest of the great nebula is a smaller one discovered by Le Gentil in 1749, and another to the south, detected by Miss Caroline Herschel in 1783. The great nebula is of an elliptical shape and considerable apparent size. The American astronomer, Bond, using a telescope of 15 inches aperture, traced it to a length of about four degrees, and a width of two and a half degrees. A beautiful photograph taken by Dr. Roberts in December, 1888, shows an extension of nearly two degrees in length, and about half a degree in width, or considerably larger than the apparent size of the full moon. Bond could not see any symptom of resolution into stars, but noticed two dark rifts or channels running nearly parallel to the length of the nebula. In Dr. Roberts’s photograph these rifts are seen to be really dark intervals between consecutive nebulous rings into which the nebula is divided. Dr. Roberts says: “A photograph which I took with the 20-inch reflector on October 10, 1887, revealed for the first time the true character of the great nebula, and one of the features exhibited was that the dark bands, referred to by Bond, formed parts of divisions between symmetrical rings of nebulous matter surrounding the large diffuse centre of the nebula. Other photographs were taken in 1887, November 15; 1888, October 1; 1888, October 2; 1888, December 29; besides several others taken since, upon all of which the rings of nebulosity are identically shown, and thus the photographs confirm the accuracy of each other, and the[165] objective reality of the details shown of the structure of the nebula.” Dr. Roberts adds: “These photographs throw a strong light on the probable truth of the Nebular Hypothesis, for they show what appears to be the progressive evolution of a gigantic stellar system.”

The largest telescopes have hitherto completely failed to resolve this wonderful object into stars. Dr. Huggins, however, finds that the spectrum is not gaseous, so that if the nebula really consists of stellar points, they must be of very small dimensions.

The question may be asked, What is the probable size and distance of this wonderful nebula? and could it be an external universe?

The temporary star which appeared near the nucleus of the nebula in August, 1885, was of the seventh magnitude. I find that our sun, if placed at the distance indicated by a parallax of 1/200th of a second, would be reduced to a star of about the eleventh magnitude, or four magnitudes fainter than the temporary star appeared to us. That is to say, the star would have been—with the assumed distance—about forty times brighter than the sun. With any greater distance, the star would have been proportionately brighter, compared with the sun. This seems improbable, and tends to the conclusion that the nebula is not an external galaxy, but a member of our own sidereal system, a system which probably includes all the stars and nebulæ visible in our largest telescopes. Dr. Common, indeed, suggests that it may be comparatively near our system. He says: “It is difficult to imagine that such an enormous object,[166] as the Andromeda nebula must be, is not very near to us; perhaps it may be found to be the nearest celestial object of all beyond the Solar System. It is one that offers the best chance of the detection of parallax, as it seems to be projected on a crowd of stars, and there are well-defined points that might be taken as fiducial points for measurement,” and he adds: “Apart from the great promise this nebula seems to give of determining parallax, there is a fair presumption that in the course of time the rotation of the outer portion may perhaps be detected by observation of the positions of the two outer detached portions in relation to the neighboring stars.”

The spiral nebulæ are wonderful objects, and were discovered by the late Lord Rosse with his great six-foot telescope. Their character has been fully confirmed by photographs taken by Dr. Roberts. One of the most remarkable of these extraordinary objects is that known as 51 Messier. It lies about three degrees southwest of the bright star Eta Ursæ Majoris—the star at the end of the Great Bear’s tail. It was discovered by Messier while comet-hunting on October 13, 1773. Telescopes of moderate power merely show two nebulæ nearly in contact, but Lord Rosse saw it as a wonderful spiral, and his drawing agrees fairly well with a photograph taken by Dr. Roberts in April, 1889. The nebula has also been photographed by Dr. Common. Dr. Roberts says: “The photograph shows both nuclei of the nebula to be stellar, surrounded by dense nebulosity, and the convolutions of the spiral in this as in other spiral nebulæ are broken up into star-like condensations[167] with nebulosity around them. Those stars that do not conform to the trends of the spiral have nebulous trails attached to them, and seem as if they had broken away from the spirals.” A tendency to a spiral structure in the smaller nebula is also visible on the original negative. Dr. Huggins finds that the spectrum is not gaseous.

The nebula known as 99 Messier is of the spiral form. It lies on the borders of Virgo and Coma Berenices, near the star 6 Comæ. In large telescopes it somewhat resembles a “Catherine wheel.” D’Arrest and Key thought it resolvable into stars. It has been photographed by M. Von Gothard.

Among the clusters and nebulæ, we may class the Magellanic Clouds, or Nubeculæ in the Southern Hemisphere, as they consist of stars, clusters, and nebulæ.

Among the so-called nebulæ are many objects which, when examined with telescopes of adequate power, are seen to be resolved into myriads of small stars; their comparative isolation from surrounding objects impresses us forcibly with the idea that they form, as it were, families of stars connected by some physical bond of union. Of these clusters, as they are called, we have naked-eye examples in the Pleiades and the “Bee-Hive” in Cancer. Others may be partially seen with a good opera-glass or binocular, but most of them require telescopes of considerable power to view them to advantage. They are of various forms and of all degrees of condensation. Some are comparatively large and irregular, others small and compressed, with the[168] component stars densely crowded. Many are of such uniform shape as to have received the name of globular clusters. These have been aptly termed “balls of stars,” and are among the most interesting objects in the stellar heavens.

The most remarkable object of this class visible in the Northern Hemisphere is that known as 13 Messier. It lies between the tolerably bright stars Zeta and Eta Herculis, nearer the latter star. It may be seen with an opera-glass as a hazy-looking star of about the sixth magnitude, with a star on each side of it. Examined with a powerful telescope, it is resolved into numerous small stars. Sir William Herschel estimated them at 14,000, but the real number is probably much less. Assuming the average magnitude of the components at twelve and a half, I find that an aggregation of 14,000 stars of this brightness would shine as a star of about the second magnitude, or a little fainter.

Another object of the globular class, but less resolvable, is that known as 92 Messier, which lies between the stars Eta and Iota in Hercules, nearer the latter. Sir William Herschel's telescopes showed it as seven or eight minutes of arc in diameter. It is considerably brighter at the centre. The larger components are easily visible in moderate-sized telescopes, but even Lord Rosse's giant instrument failed to resolve the central blaze. There is no doubt, however, that it consists wholly of small stars, as the unerring eye of the spectroscope shows a stellar spectrum, similar to that of the neighboring 13 Messier.

[169] Drawing of star regions Fig. 17.—The Region of Boötes and Hercules

Another fine example of the globular class is 5 Messier, which lies closely north, preceding the fifth magnitude star, 5 Serpentis. It is considerably compressed at the centre. Sir William Herschel counted 200 stars, but failed to resolve the central nebulosity. Messier, its discoverer, found it visible with a telescope only one foot long.

[170]

Another fine object is 3 Messier, in Boötes. Admiral Smyth describes it as "a brilliant and beautiful globular aggregation of not less than 1,000 small stars." It is beyond the power of small telescopes, but it was resolved by Buffham, even in the centre, with a 9-inch reflector.

Numerous fine examples of the globular class are found in the Southern Hemisphere, which indeed seems to be richer in these marvelous objects than the northern sky. Of these the most interesting are those known as Omega Centauri and 47 Toucani. Omega Centauri, from its great apparent size—about two-thirds of the moon's diameter—and its visibility to the naked eye, may perhaps be considered as the most remarkable object of its kind in the heavens. It shines as a hazy star of the fourth magnitude, and I have often so seen it in the Punjab sky. Its large size and globular form are clearly visible in a binocular field-glass, but, of course, its component stars are far beyond the reach of such an instrument. Sir John Herschel, observing it with his large telescope at the Cape of Good Hope, found it a "truly astonishing object. All clearly resolved into stars of two magnitudes, viz., thirteen and fifteen, the larger lying in lines and ridges over the smaller;... the larger form rings like lace-work on it." If we take the average magnitude of the components at thirteen and a half, the apparent brightness of the cluster would imply that it contains about 15,000 stars. Photo of Nebula The Great Nebula in the Constellation Cygnus

The other wonderful cluster is that known as 47 Toucani, which lies close to the smaller Magellanic[171] Cloud. It is smaller in apparent size than Omega Centauri, but Dr. Gould, observing it at Cordoba, speaks of it as "one of the most impressive and perhaps the grandest of its kind in either hemisphere," and he estimates its magnitude at four and a half, as seen with the naked eye. It is thus described by Sir John Herschel: "A most magnificent globular cluster. It fills the field with its outskirts, but within its more compressed part I can insulate a tolerably defined, circular space, of 90″ diameter, wherein the compression is much more decided, and the stars seem to run together, and this part, I think, has a pale pinkish or rose color, which contrasts, evidently, with the white light of the rest. The stars are equal, fourteen magnitude, immensely numerous and compressed.... Condensation in three distinct stages.... A stupendous object." Sir John Herschel's drawing of this cluster reminds one of a swarm of bees, and perhaps suggested to Tennyson the lines: "Clusters and beds of worlds, and bee-like swarms Of suns and starry streams."

There are other interesting specimens of the globular class in the Southern Hemisphere, but not of such large apparent dimensions as those already described. Of these may be mentioned 22 Messier, which lies about midway between the stars Mu and Sigma Sagittarii. It is described by Sir John Herschel as a fine globular cluster, with stars of two magnitudes, namely eleven or twelve, and fifteen or sixteen, the larger being visibly reddish, and he suggested that it consists of "two layers, or one shell[172] over another." Owing to the comparative brightness of the larger components, this cluster forms a good object for small telescopes. I saw the brighter stars well with a 3-inch refractor in the Punjab sky, but, of course, the greater portion of the cluster has a nebulous appearance in a telescope of this size.

Between Alpha and Beta Scorpii there is a condensed globular cluster. With small telescopes it very much resembles a telescopic comet, but with larger instruments its true character is revealed. Sir William Herschel considered it "the richest and most condensed mass of stars in the firmament." In May, 1860, a "temporary star" of the seventh magnitude suddenly appeared in the centre, almost blotting out the cluster by its superior light. The star faded away before the end of June of the same year, and has not been seen with any certainty since. It has been suggested that this temporary star lay between the cluster and the earth, but it seems to me much more probable that the outburst took place in the cluster itself, and that it was possibly caused by a collision between two of the component stars, or by a swarm of meteors rushing with a high velocity through the cluster.

The beauty and sublimity of the spectacle presented by these globular clusters, when viewed with a powerful telescope, is such as can not be adequately described, and it has been said that when seen for the first time, “few can refrain from a shout of rapture.” The component stars, although distinctly visible as points of light, defy all attempts at counting them, and seem literally innumerable. Placed[173] like a mass of glittering diamond-dust on the dark background of the heavens, they impress us forcibly with the idea that if each of these lucid points is a sun, the thousands which seem massed together in so small a space must be in reality either relatively close and individually small, or else the system of suns must be placed at a distance almost approaching the infinite.

The distance of these globular clusters from the earth is, however, certainly very great. Attempts to accurately determine their position in space have not been attended with success. As the component stars are at practically the same distance from the eye, we have no comparison stars to measure from, and their exact distance, therefore, remains unknown. We may, however, estimate their probable distance with some show of plausibility. We may assume that the stars of the Hercules cluster would, if concentrated in a point, shine as a star of about the fourth magnitude. As the components are of about the twelfth and thirteenth magnitudes, this would imply that the cluster consists of about 2,500 stars. With the data assumed, we may therefore conclude that the components of the Hercules cluster are suns of comparatively small size, separated by considerable distances, but apparently massed together by the effect of distance.

Among less condensed star clusters there are many interesting objects. The Pleiades have been already referred to. On a photograph of this remarkable group, taken at the Paris Observatory, over 2,000 stars can be counted of all degrees of brilliancy, from[174] those visible without optical aid down to points of light so faint as to be invisible to the eye in the telescope with which they were photographed. Here we have a cluster of probably larger size than that in Hercules, probably at a greater distance from the earth, and with its larger components of considerably greater mass than our sun.

Near the bright star Pollux, I see a small cluster of stars of about the seventh and eight magnitudes, which, with a binocular field-glass, very much resembles the Pleiades as seen with the naked eye. A smaller cluster (known as 39 Messier) may be seen near the star Pi Cygni.

The well-known Chi Persei may be also seen with an opera-glass, but a telescope is necessary to show the component stars to advantage, and the larger the telescope the greater the number of faint stars in these wonderful objects.

The cluster known as 35 Messier, a little north of the star Eta Geminorum, is visible in an opera-glass, but a small telescope is required to see the component stars. A well-marked clustering tendency is visible among the brighter stars of the group, two, three, four, and sometimes five stars being grouped together in subordinate collections. Admiral Smyth says: “It presents a gorgeous field of stars from the ninth to the sixteenth magnitude, but with the centre of the mass less rich than the rest. From the small stars being inclined to form curves of three or four, and often with a large one at the root of the curve, it somewhat reminds one of the bursting of a sky-rocket.” This tendency to “stream” formation in[175] the components of star clusters is also well marked in a photograph of the cluster 38 Messier (kindly sent to me by MM. Henry of the Paris Observatory). It was described by Webb as “a noble cluster arranged in an oblique cross,” and Smyth says: “The very unusual shape of this cluster recalls the sagacity of Sir William Herschel’s speculations upon the subject, and very much favors the idea of an attractive power lodged in the brightest part. For although the form is not globular, it is plainly to be seen that there is a tendency toward sphericity, by the swell of the dimensions as they draw near the most luminous part, denoting, as it were, a stream or tide of stars, setting toward the centre.”

Sir W. Herschel, speaking of a compressed cluster in Perseus, says “the large stars are arranged in lines like interwoven letters,” and Webb says “it is beautifully bordered by a brighter foreshortened pentagon.”

Observing with a 3-inch telescope in India, I noticed a beautiful cluster of stars, about 4° north of Gamma and Upsilon Scorpii, resembling in shape a bird’s foot, with remarkable streams of stars. This cluster is visible to the naked eye as a star of about the fifth magnitude.

Although these loosely associated star clusters do not show such evidence in favor of family connection as the more closely compacted globular clusters, still we can hardly escape from the conviction that their apparent aggregation is really due to some physical bond of union, and not merely the result of a fortuitous scattering of stars at different distances in the line of sight.

[176] THE GREAT NEBULA OF ORION.—Sir Robert S. Ball

The telescope, ever an ally in the study of the heavens, is in this part of the science absolutely indispensable. In other branches of astronomy we can learn something without its aid. Indeed, many great astronomical discoveries were made long before the telescope was invented. But ere this memorable event in the history of science it was impossible for us to know anything of the existence of the nebulæ. It is indeed true that there is one of these objects which can be just detected by the naked eye. It lies in the constellation of Andromeda, where, on a clear and dark night, a faint spot of light can just be discerned by a good eye. But a mere glimpse gives us really no adequate notion of the true character of the object. It might only, so far as the naked eye discloses its nature, be a cluster of stars like that we have already discerned in Perseus, or like the similar group that, under the name of the Beehive, is comparatively familiar in the constellation of Cancer. With the single exception of the nebula in Andromeda, all the objects so called are entirely telescopic, yet how important a constituent the nebulæ form in the contents of the heavens will be shown by a look at some of the lists of these objects. There are now several thousands of nebulæ known, and their positions in the sky, as well as the details of their appearances, are set forth in the catalogues.

The most glorious constellation of stars in the[177] firmament is undoubtedly that of Orion. This splendid group is seen in the south during the winter months, and toward the close of January it is situated in a very convenient position for observing early in the evening. The group is specially characterized by the number of unusually bright stars which it includes, and the three stars in the centre, forming the so-called Belt of Orion, is as well known a celestial figure as the sky contains. Directly under the belt are three much smaller stars nearly in a line, which points straight upward to the middle star of the belt. These three lower stars are usually known as the sword handle of Orion, this being the position which they occupied in the fanciful old sketches of the constellation. The three stars of the sword handle of Orion are plunged in the Great Nebula. This object can not be seen by the unassisted eye, though doubtless around the central star a little haziness is perceptible, and even the slightest telescopic aid will suffice to indicate that the central star of the sword handle is attended by a surrounding glow of light, which renders it quite unlike other stars. This can indeed be sufficiently shown with an ordinary opera-glass, one glance through which will awaken in the beholder a keen desire to study the object under more favorable conditions. But to do justice to the object, telescopes of large power are desirable.

To realize fully the magnificence of the Great Nebula, the observer who is being introduced to the object for the first time should not, strange to say, direct the telescope at the nebula; the instrument should rather be pointed at the heavens, just a little[178] to the west of the nebula. The clock driving the equatorial should not be started, and the observer should take his seat and look through the eye-piece before the nebula has entered the field. He will see, no doubt, a few stars on the black background, which gradually pass in procession across his field of view. This is merely the ordinary diurnal journey of the heavens, by which all the objects move slowly from east to west; I ought rather to say appear to move, for, of course, the motion on the heavens is only apparent, the fact being that it is the earth which is turning round.

After the observer’s eye for a minute or so has become familiarized with the dark aspect of the heavens under ordinary circumstances, he will begin to perceive on the eastern side (it will appear in the telescope no doubt as on the western side) a faint dawn of light. Gradually there will steal across his field of view a sort of ghostlike luminosity that is in marked contrast to the darkness in the rest of the field; as the seconds move on, this object will disclose itself until the full splendor of the Great Nebula comes into view; then the entire field will be filled with the light, and then it will gradually advance and gradually pass away again to emphasize the contrast between the brilliance of the nebula and the darkness of the sky. Unless this method is adopted, the full interest of a telescopic view of the Great Nebula is not attained, for when the entire field is full of the glow the beginner will hardly recognize the nebula. He will be apt to think that the fainter part of the field he sees is the ordinary[179] groundwork of the sky, and this illusion can only be dispelled by enabling him to witness the actual contrast in the way I have described. The central portions of the nebula are, however, so brilliant and so wonderfully marked with interesting detail, that even a small instrument will suffice to reveal much of its beauties.

In the centre of the nebula is the star known to astronomers at Theta Orionis, the most prominent star of the sword handle. To the eye this looks like an ordinary star, but the telescope speedily dispels that notion. Theta Orionis is found to consist of four, or rather six, stars all so close together that the unaided eye fails to distinguish them separately. A structure so complex gives to this star quite a special, indeed a unique, interest, wholly apart from the marvelous nebula of which it is the focus. We must dwell a little on the peculiarities of this star. We are familiar with stars which are called double; there are indeed some ten thousand objects so designated known to astronomers and duly registered in catalogues.

Many of these double stars are objects of extreme telescopic beauty; sometimes they offer to our admiration a delightful contrast of colors; perhaps one will be topaz color and the other bluish, or on rare occasions a pair of emerald gems will be seen with an invisible band of mutual connection. Sometimes triple stars are found, in which three stars are obviously in alliance; but multiple

stars of greater complexity are comparatively rare; and so marvelous a spectacle as Theta Orionis, in which no fewer[180] than six stars are obviously an allied group, is almost unique. It is not a little remarkable that we find the most exquisite multiple star which the sky can show, beautifully framed or set in the centre of the grandest of the nebulæ. Of course it might conceivably happen that the apparent concourse of these objects was fortuitous. The actual phenomenon could be accounted for by the belief that the Great Nebula was either very much nearer or very much further than the multiple star, and that they chanced to lie in the same line of sight, and had no other connection. But to me it appears that this view is quite at variance with every reasonable probability; that the most wondrous multiple star should have happened to lie in line with the very centre of the most wondrous nebula would have been a coincidence against the occurrence of which the probabilities were almost infinite. There can scarcely be any doubt that the multiple star and the Great Nebula are part of the same system, and that the star is, in truth, placed in the middle of the nebula, as it actually appears to be.

And now as to the composition of this mysterious object.

The word nebula means, of course, a little cloud, but the expression is apt to be a misleading one. In a sense no doubt they are little, inasmuch as the patch of the sky which a nebula covers would be small compared with one of our ordinary clouds. Indeed, a nebula which covered as large an apparent part of the sky as the size of the moon would be ranked as a large object of its class, while even the greatest of[181] them is perhaps not more than ten or twelve times as great. Nor is the word cloud, as applied to nebula, an appropriate one. What we mean by a cloud is only a vast mass of watery vapor raised by the sun from the sea, and poised aloft until such time as it shall be again dispersed into invisible water, or until it shall descend to the earth as rain. Such clouds are, of course, within the limits of our atmosphere, and are rarely more than a few miles above the earth's surface. The light which renders clouds visible only comes from reflected sunbeams, and consequently at night clouds become invisible, though the astronomer is often only too unpleasantly made acquainted with their presence by the opacity with which they shut out the stars from his view.

Utterly different in all respects are the nebulæ. They are not masses of watery vapor. It may no doubt possibly be that water in some form is there, but it is not water which we see. We are looking at some gaseous material of a bluish hue. The light with which it glows is no reflected sunlight. The nebula is indeed indebted to no foreign source for that weird—I had almost said ghostlike—radiance which it gives forth. The light comes from the nebula itself. But how, it may well be asked, should a purely gaseous substance be able to radiate forth light? It is easy for us to comprehend how stars or suns or comparatively solid bodies can, in virtue of their tremendous temperature, glow with heat like red-hot or white-hot iron. It is true that flame is gas in an incandescent state, but in flame a vehement chemical union of oxygen with some other substance[182] is in progress, and this is the source of the heat and the light that flame gives forth. We can not regard the Great Nebula in Orion as originating in anything resembling flame.

We can, however, in our physical laboratories arrange an experiment which seems to throw some light on the composition of the nebula. Into a glass tube a small quantity of hydrogen gas is admitted, the air having been previously extracted. Then, by means of two wires, one at each end of the tube, an electric current is transmitted through the gas. Here there is no combustion; the gas is merely the vehicle by which the electricity flows from one pole to the other. In doing so the gas instantly begins to glow with an intense bluish light, and a very beautiful effect is produced, which can be renewed or terminated at will by simply making or breaking the electric current. It would seem as if the gas we see in the nebula were in a condition somewhat analogous to the gas in the tube. I do not mean that the passage of electricity through the nebula is the source of its luminosity. There is, indeed, no ground for such a supposition. It is the property of electricity when passing through a conductor to warm that conductor; thus we know that if a powerful current be transmitted through a wire of the most infusible of all metals, platinum, the wire will not only get warm, but it may become red hot, white hot, and even melt under the influence of the heat which is generated. In those beautiful incandescent electric lamps which are now happily coming into extensive use a current of electricity flows through a filament of carbon, and[183] kindles that exquisite incandescence which is maintained while the current flows. It would appear that so long as the electricity is flowing through the glass tube its action on the gas is to impart a very high temperature. It is in consequence of this temperature that the gas glows. Now we can offer a reasonable account of the luminosity of the Great Nebula in Orion. The particles of gaseous or vaporous material of which it is formed are of an extremely high temperature, sufficient to enable them to glow with the brilliancy which renders them visible.

It is now almost twenty years since a marvelous accession to our knowledge of such objects as the Great Nebula in Orion was made by Dr. Huggins. I have used our gas hydrogen as an illustration in describing the character of the nebula, but I have now to add that the presence of hydrogen is no mere fiction but a substantial verity. Truly we here open up one of the most marvelous

chapters which science has to disclose. The chemist can analyze the different substances on the earth with his test tubes, and he can tell the elements of which they are composed. But in this old-fashioned chemistry it was at least reasonable for the chemist to demand a portion of the substance he was expected to analyze. Unless he were provided with a sample, how could it be possible for him to grind it up or submit it to the various operations of his laboratory? In these modern days the chemist can perform operations of which his predecessors never even dreamed. No doubt the old method is still used—nay, is indeed at this moment cultivated with greater skill and means than[184] in any previous age—but side by side with the old method, and as an invaluable supplement thereto, the new method of chemical research, called spectrum analysis, has been created, and has already conducted to many profoundly interesting discoveries in the most varied branches of science.

In the application of the spectroscopic method it is not indispensably necessary that we actually have a fragment of the substance; all we require is a beam of light which that substance can be made to yield when heated to a sufficiently high temperature.

When a beam of the nebular light is transmitted through the prisms, it declares at once that the object from which that light has come is totally different from a star like the sun. Instead of the beautifully colored band, decked in all the glowing hues of the rainbow, the nebular beam is seen to be composed simply of six or seven widely separated strips. It is important to test the character of the light in these strips. Fortunately this can be done in a way that is completely satisfactory. We can produce artificial lights from known sources, and observe them through the spectroscope simultaneously with the light of the nebula.

There are in the composition of this globe some sixty or seventy different elementary substances, and under suitable conditions each one of these substances can afford a perfectly characteristic spectrum. Thus the way of making the comparison with the nebula is to try the different elements one after another, until one can be discovered which pours forth a light that behaves under the prism as does the light[185] from the nebula. Pursuing this inquiry, Dr. Huggins found that when hydrogen gas was ignited to incandescence by the passage of electricity, it emitted light which, after passage through the prisms, came to coincidence with one of the lines in the spectrum of nebula; and the hydrogen character of two of the other lines has been since demonstrated. It was thus established that hydrogen is one of the constituents of the Great Nebula in Orion. Further confirmation of this important discovery was forthcoming when the photographs of the spectrum of the Great Nebula were subsequently obtained. On these photographs lines were present which are constituted by light of such a nature as to be wholly invisible to the eye, though perceptible on the photographic plate. It is of the greatest interest to discover that these invisible rays from the nebula are also indicative of the presence of hydrogen. Thus we obtain a beautiful confirmation of the fact that the nebula is partly composed of glowing hydrogen.

There are, however, some remaining lines, the character of which has not yet been ascertained.

It would be a little premature to assert that there must be some substance in the Great Nebula not at present known to us on the earth. This would be, no doubt, one interpretation of the facts. We must, however, admit the possibility of another explanation. It is frequently found that the lines yielded by an incandescent material vary to some extent when the physical conditions of temperature and of pressure are modified. It is, therefore, not impossible[186] that the unknown lines in the spectrum of the Great Nebula may be due to some element known to us, but which has not yet been tested under the conditions which would make it yield the particular rays we are speaking of.

The composition of a nebula as disclosed to us by these researches is very instructive. Here we are looking at an object which seems to lie at the very limits of the visible universe—an object so remote that our attempts to fathom its distance are quite unsuccessful; yet in this inconceivably distant part of our system we find at least one ingredient which we know well on the earth. Previous to actual trial no one would have expected, I think, to find the Great Nebula largely constituted from such a familiar element as hydrogen. This gas enters into the composition of water, and is thus an element of extreme abundance on the earth. That an element so common with us here should also be abundant in these awfully distant regions of the universe is one of the most astonishing facts that modern science has revealed.

As the eye follows these ramifications of the Great Nebula, ever fading away in brightness until it dissolves in the blackness of the sky; as we look at the multitudes of bright stars which sparkle out from the depths of the great glowing gas; as we ponder on the marvelous outlines of a portion of the nebula, we are tempted to ask what the true magnitude of this object must really be. Here, again, we have to confess that science is unable to satisfy this very legitimate curiosity. The only means of learning[187] the true length and breadth of a celestial object depends upon our first having discovered the distance from us at which the object is situated. Unhappily we are, as I have said, entirely ignorant of what this distance may be in the case of the Great Nebula in Orion.

Our ordinary methods of conducting such an inquiry are hardly applicable to such an object, and its position so near the Equator introduces fresh difficulties into the problem. We shall, however, certainly not err on the side of exaggeration if we assert that the Great Nebula must be many millions of times larger than that group of bodies which we call the Solar System. COLORED, DOUBLE, MULTIPLE, BINARY, VARIABLE AND TEMPORARY STARS.—J. E. Gore

On a clear night a careful observer will notice a marked difference in the colors of the brighter stars. The brilliant white or bluish-white light of Sirius, Rigel, and Vega contrasts strongly with the yellowish color of Capella, the deeper yellow, or orange, of Arcturus, and the ruddy light of Aldebaran and Betelgeuse. These colors are, however, limited to various shades of yellow and red. No star of a decided blue or green color is known, at least among those visible to the naked eye in the Northern Hemisphere. The third magnitude star Beta Libræ is described by Webb as of a "beautiful pale green hue," but probably such a tint in the light of this star will to most people prove quite imperceptible. Dr.[188] Gould, observing it in the Southern Hemisphere—under, of course, more favorable conditions—says: "There is a decidedly greenish tinge to the light of Beta Libræ, although its color can not properly be called conspicuous."

Among the ruddy stars visible to the naked eye, Mu Cephei, Herschel's "garnet star," is generally admitted to be the reddest, but it is not sufficiently bright to enable its color to be well distinguished without the aid of an opera-glass. With such an instrument, however, its reddish hue is striking and beautiful, and very remarkable when compared with other stars in its vicinity. Like so many of the red stars, Mu Cephei is variable in its light, but seems to have no regular period, and often remains for many weeks without perceptible change. It may be seen near the zenith in the early evening hours toward the end of October, and when in this position its ruddy color is very conspicuous.

Among the brightest stars, Betelgeuse is perhaps the reddest, and the contrast between its ruddy tint and the white color of Rigel in the same constellation (Orion) is very noticeable. Like Mu Cephei, Betelgeuse is irregularly variable in its light, but not to such an extent, and, like the "garnet star," it frequently remains for protracted periods nearly constant in brightness. There are other cases of reddish color among the naked-eye stars. Among these may be mentioned Antares (Alpha Scorpii), Alphard (Alpha Hydræ), noted as red by the Persian astronomer Al-Sûfi, in the Tenth Century, and called by the[189] Chinese "The Red Bird"; Eta and Mu Geminorum; Mu and Nu Ursæ Majoris; Delta and Lambda Draconis; Beta Ophiuchi; Gamma Aquilæ, and others in the Southern Hemisphere.

But it is among the stars below the limit of naked-eye vision that we meet with the finest examples of the red stars. Some of these are truly wonderful objects. The small star, No. 592 of Birmingham's Catalogue of Red Stars (No. 713 of Espin's edition), which lies a little south of the 5½ magnitude star 79 Cygni, was described as "splendid red" by Birmingham, "very deep red" by Copeland and Dreyer, and "orange vermilion" by Franks. The star 248 Birmingham, which lies about 5° south of Gamma Hydræ, is another fine specimen. Birmingham described it as "fine red" and "ruby"; Copeland as "brown red"; Dreyer as "copper red"; and Espin as "magnificent blood red." This star is variable in light, as the estimates of magnitude range from 6.7 to below 9. About 3° to the northeast of this remarkable object is another highly-colored star, known as R Crateris. It is easily found, as it lies in the same telescopic field of view with Alpha Crateris, a 4½ magnitude star. Sir John Herschel described it as "scarlet, almost blood-color; a most intense and curious color." Birmingham called it "crimson"; and Webb "very intense ruby." Observing it with a 3-inch refractor in India in 1875, I noted it as "full scarlet." It varies in light from above the eighth magnitude to below the ninth, and has near it a star of the ninth magnitude of a paler blue tint.

[190]

Another very red star is No. 4 of Birmingham's Catalogue, which will be found about 5° north, preceding the great nebula in Andromeda. It is of about the eighth magnitude, and may be well seen with a 3-inch refractor. Krüger describes it as "intensiv roth"; Birmingham as "fine red" and "crimson"; Franks as "fine color, almost vermilion"; and Espin as "intense red color, most wonderful."

Another fine object is R Leporis, which forms roughly an equilateral triangle with Kappa and Mu Leporis. This is also variable from 6½ to 8½ magnitude. It was discovered by Hind in 1845, and described by him as "of the most intense crimson, resembling a blood-drop on the background of the sky; as regards depth of color, no other star visible in these latitudes could be compared with it." Schönfeld called it "intensiv blutroth," but Dunér, observing its spectrum in 1880, gives its color as a less intense red than that of other stars. Possibly it may vary in color as well as in light.

The variable star U Cygni, which lies between Omicron and Omega Cygni, is also very red. Webb described it as showing "one of the loveliest hues in the sky." It varies from about the seventh to 11½ magnitude, with a period of about 461 days.

Another deeply colored star is the well-known variable R Leonis. Hind says: “It is one of the most fiery-looking variables on our list—fiery in every stage from maximum to minimum, and is really a fine telescopic object in a dark sky about the time of greatest brilliancy, when its color forms a striking contrast with the steady white light of the sixth magnitude[191] a little to the north.” This latter star is 19 Leonis.

In the Southern Hemisphere there are some fine examples of red stars. Epsilon Crucis, one of the stars in the Southern Cross, is very red. Mu Muscæ is described by Dr. Gould as of “an intense orange red.” Delta2 Gruis is a very reddish star of about the fourth magnitude. Pi1 Gruis was observed by Gould as “deep crimson,” and forming a striking contrast with its white neighbor Pi2 Gruis, which he notes as “conspicuously white.” The variable L2 Puppis is described as “red in all its stages, and remarkably so when faint.” Miss Clerke, observing—at the Cape of Good Hope—R Doradûs, another southern variable, says: “This extraordinary object strikes the eye with the glare of a stormy sunset,” and with reference to the variable R Sculptoris, described by Gould as “an intense scarlet,” she says: “The star glows like a live coal in the field,” a description I have found myself very applicable to other small red stars.

An eighth magnitude star about 5° north of Beta Pictoris is noted by Sir John Herschel, in his Cape Observations, as “vivid sanguine red, like a blood-drop. A superb specimen of its class.” With reference to a star of about 8½ magnitude in the field with Beta Crucis, Herschel says: “The fullest and deepest maroon red; the most intense blood-red of any star I have seen. It is like a drop of blood when contrasted with the whiteness of Beta Crucis.”

Of stars of other colors, the asserted green tint of Beta Libræ has already been referred to. Among[192] the brighter stars of the Southern Hemisphere, Theta Eridani, Epsilon Pavonis, Upsilon Puppis, and Gamma Tucanæ are said to be decidedly blue. The wonderful cluster surrounding the star Kappa Crucis contains several bluish, greenish and red stars, and is described by Sir John Herschel as resembling “a superb piece of fancy jewelry.”

Among the double stars we find many examples of colored suns. Of these may be mentioned Epsilon Boötis, of which the colors are “most beautiful yellow” and “superb blue,” according to Secchi; Beta Cephei, “yellow and violet”; Beta Cygni, “golden yellow and smalt blue”; Gamma Delphini, of which I noted the colors in 1874 as “reddish yellow and grayish lilac”; Alpha Herculis, “orange and emerald or bluish green,” and described by Admiral Smyth as “a lovely object, one of the finest in the heavens”; Zeta Lyræ, “pale yellow and lilac” (Franks); and Beta Piscis Australis, of which I observed the colors in India as white and reddish lilac.

Some distant telescopic companions to red stars have been described as blue. This may be in some case due, partly at least, to the effect of contrast. In others the blue color seems to be real. This has been shown spectroscopically to be the case with the bluish companions of Beta Cygni.

The physical cause of the difference of color is still more or less a matter of mystery. Although we can not consider it proved that the red stars are cooling and “dying out” suns, as has been suggested, we may, I think, conclude that their temperature, although doubtless very high, must be lower than that[193] of the white stars. We know that a bar of iron when heated to redness is not so hot as when raised to “white heat,” and although the analogy between hot iron and stellar photospheres may not be a perfect one, it seems probable that the higher the temperature of a star, the whiter its color will be. Most of the white stars, as Sirius, Vega, and those only yellow or slightly colored, show spectra of Secchi’s first and second types, while the great majority of the red stars exhibit banded spectra of the third and fourth types.

To this rule there are, however, like other rules, some notable exceptions. For instance, Aldebaran, Alpha Hydræ, Xi Cygni, and 31 Orionis, although distinctly reddish stars, show well-marked spectra of the second or solar type. On the other hand, Rho Ursæ Majoris and Omega Virginis, which, according to Dunér, are only slightly yellow, have well-marked spectra of the third type.

An apparent change of color seems in some cases to be well established. The supposed red color of Sirius in ancient times is well known. A certain established change is found in the case of the famous variable star Algol, which is distinctly described as red by Al-Sûfi in the Tenth Century. It is now pure white, or nearly so, and this is probably the best attested instance on record of change of color in a bright star.

Schmidt’s Nova Cygni of 1876 was noted as “golden yellow” on the night of its discovery. When it had faded to the eighth magnitude, Dr. Copeland called it “decided red,” but when examined at Lord[194] Crawford’s observatory in September, 1877, its color was recorded as “faint blue”! The new star in the Andromeda nebula was considered to be yellowish or reddish by most observers when near its maximum, but about a month later its color was noted as “bluish.”

Among the red and variable stars, there are many suspected cases of color variation. Espin and other observers have noted that the wonderful variable Mira Ceti is much less red at maximum than at minimum. My own observations confirm this. When at its maximum brightness, Mira does not seem to me a very highly-colored star, while at one of its minima I noted it as “fiery red.” Possibly, however, the great difference between its maximum and minimum brilliancy may have an influence on estimations of its color. The remarkable variable Chi Cygni is said to be “strikingly variable in color.” Espin’s observations in different years show it “sometimes quite red, at others only pale orange red.” The star Birmingham 118 was described by Schjellerup in 1863 as “decided red,” but it was found yellow by Secchi in 1868; “bluish” by Birmingham, 1873-76; “no longer red” by Schjellerup in March, 1876; and “white” by Franks in 1885. Espin omits it from his revised edition of Birmingham’s Catalogue.

Birmingham 169 was found red by Struve, blue or bluish-white by Birmingham in 1874, and white at Greenwich in the same year. Espin also saw it white in March, 1888. The star Birmingham 30, which lies close to Phi Persei (54 Andromedæ), was described[195] by Schweizer as a “red star with a little disk” in January, 1843; Birmingham noted it as “light red” in December, 1875; Copeland “deep red” in January, 1876; and Dreyer “reddish” in September, 1878; but Espin, in November and December, 1887, found it “certainly not red, and nothing peculiar in the star’s appearance.” It might be expected that these curious changes of color, if real, would be accompanied by corresponding changes in the star’s spectrum. Such may be the case, and observations in this direction would probably lead to some interesting results.

There seems to be some law governing the distribution of the colored stars. The white stars appear to be most numerous, as a rule, in those constellations where bright stars are most abundant, for instance, in Orion, Cassiopeia, and Lyra; yellow and orange stars in large and ill-defined constellations, such as Cetus, Pisces, Hydra, Virgo, etc. The very reddish stars are most numerous in or near the Milky Way, and one portion of the Galaxy—between Aquila, Lyra, and Cygnus—was termed by Birmingham “the red region in Cygnus.”

Many of the stars when examined with a good telescope are seen to be double, some triple, and a few quadruple, and even multiple. These when viewed with the naked eye, or even a powerful binocular, seem to be single, and show no sign of consisting of two components. These telescopic double stars should be carefully distinguished from those which appear very close together with the naked eye, and which in opera-glasses or telescopes[196] of small power might be mistaken for wide double stars by the inexperienced observer. These latter stars, such as Mizar—the middle star in the tail of the Great Bear—and its small companion, Alcor, have been called “naked-eye doubles,” but they are not, properly speaking, double stars at all. Telescopic double stars are far closer, and even the widest of them could not possibly be seen double without optical aid, even by those who are gifted with the keenest vision. Of these so-called “naked-eye doubles,” we may mention Alpha Capricorni, which on a very clear night may be seen with the naked eye to consist of two stars. On a very fine night two stars may be seen in Iota Orionis, the most southern star in Orion’s Sword. The star Zeta Ceti has near it a fifth magnitude star, Chi, which may be easily seen with the unaided vision. The star Epsilon Lyræ (near Vega) is a severe test for naked-eye vision. Bessel, the famous German astronomer, is said to have seen it when thirteen years of age. Omicron Cygni (north of Alpha and Delta Cygni) forms another naked-eye double, and other objects of this class may be noticed by a sharp-eyed observer.

The star Mizar, already referred to, is itself a wide telescopic double, and it seems to have been the first double star discovered with the telescope (by Riccioli in 1650). It consists of two components, of which one is considerably brighter than the other. It will give an idea of the closeness of even a “wide” telescopic double when we say that the apparent distance between Mizar and Alcor is nearly forty times[197] the distance which separates the close components of the bright star. From this it will be seen that even a powerful binocular field-glass would fail to show Mizar as anything but a single star. The components may, however, be well seen with a 3-inch telescope, or even with a good 2-inch. The colors of the two stars are pale green and white. Between Mizar and Alcor is a star of the eighth magnitude, and others fainter. Mizar was the first double star photographed by Bond.

The Pole Star has a small companion at a little greater distance than that which separates the components of Mizar, but owing to the faintness of this small star, the object is not so easy as Mizar.

The star Beta Cygni is composed of a large and small star, of which the colors are described as “golden yellow and smalt blue.” This is a very wide double, and may be seen with quite a small telescope. Another fine double star is that known to astronomers as Gamma Andromedæ. The magnitudes of the components are about the same as those of Mizar, but a little closer. Their colors are beautiful (“gold and blue”). This is one of the prettiest double stars in the heavens. It is really a triple star, the fainter of the pair being a very close double star; but this is beyond the reach of all but the largest telescopes. The star Gamma Delphini is another beautiful object, the components being a little more unequal in magnitude, but the distance between them about the same as in

Gamma Andromedæ. I have noted the colors with a 3-inch telescope as “reddish yellow and grayish lilac.” Gamma Arietis, the faintest of the[198] three well-known stars in the head of Aries, is another fine double star, a little closer than Gamma Delphini. This is an interesting object, from the fact that it was one of the first double stars discovered with the telescope—by Hooke, in 1664, when following the comet of that year.

Another beautiful double star is Eta Cassiopeiæ, the components being about equal in brightness to those of Gamma Delphini, but the distance less than one-half. The colors are, according to Webb, yellow and purple; but other observers have found the smaller star garnet or red. This is a very interesting object, the components revolving round each other, and forming what is called a binary star.

Another fine double star is Castor, which is composed of two nearly equal stars separated by a distance about half that between the components of Gamma Andromedæ. This is also a binary, or revolving double star, but the period is long. Gamma Virginis is another fine double star, with components at about the same distance as those of Castor, and the colors very similar. It is also a remarkable binary star.

Among double stars of which the components are closer than those mentioned above, but which are within the reach of a good 3-inch telescope—a common size with amateur observers—the following may be noticed: Alpha Herculis, colors, orange or emerald green; the light of this star is slightly variable. Gamma Leonis, another binary star with a long period; colors, pale yellow and purple. Epsilon Boötis, a lovely double star, the colors of which[199] Secchi described as “most beautiful yellow, superb blue.”

For observers in the Southern Hemisphere, the following fine double stars may be seen with a 3-inch telescope: Alpha Centauri; this famous star, the nearest of all the fixed stars to the earth, is also a remarkable binary; its period, as recently computed by Dr. See, is eighty-one years. Theta Eridani is a splendid pair, but closer than Alpha Centauri. It is, however, an easy object with a 3-inch telescope, and with a telescope of this size I noted the colors in India as light yellow and dusky yellow. The star known as *ƒ* Eridani is a very similar double to Theta, but the components are fainter. I noted the colors in India as yellowish-white and very light green.

Of triple, quadruple, and multiple stars, there are several which may be well seen with a small telescope. Of these may be mentioned Iota Orionis, the lowest star in the Sword of Orion, which consists of a bright star accompanied by two small companions. In Theta Orionis, the middle star of the Sword, four stars may be seen forming a quadrilateral figure, known to observers as the “trapezium.” There are two fainter stars in this curious object, which lie in the midst of the Orion nebula, but a somewhat larger telescope is required to see them. Within the trapezium are two very faint stars, which are only visible in the largest telescopes. In Sigma Orionis—a star closely south of Zeta, the lowest star in Orion’s Belt—six stars may be seen with a 3-inch telescope.

Double and multiple stars may be either optical or real. Optical double stars are those in which the[200] component stars are merely apparently close together, owing to their being seen in nearly the same direction in space. Two stars may seem to be close together, while, in reality, one of them may be placed at an immense distance behind the other. Just as two lighthouses at sea may, on a dark night, appear close together when viewed from a certain point, whereas they may be really miles apart. In the case of double stars it is, of course, always difficult to determine whether the apparent closeness of the stars is real or merely optical. But when, from a long series of observations of their relative position, we find that one is apparently moving round the other, we know that the stars must be comparatively close, and linked together by some physical bond of union. These most interesting objects are known to astronomers as binary, or revolving double stars. The probable existence of such objects was predicted from abstract reasoning by Mitchell in the Eighteenth Century; but the discovery of their actual existence was made by Sir William Herschel, while engaged on an attempt to determine the distance of some of the double stars from the earth. Unlike the planetary orbits, which are nearly circular, at least those of the larger planets of the Solar System, it is found that the orbits of these double stars differ, in many cases, widely from the circular form, in some cases, indeed, approaching in shape more the orbit of a comet than a planet.

The binary stars are among the most interesting objects in the heavens. The number now known probably amounts to nearly one thousand. In most[201] of them, however, the motion is very slow, and in only about seventy cases has the change of position, since their discovery, been sufficient to enable an orbit to be computed.

Savary, in 1830, was the first astronomer who attempted to compute the orbit of a binary star, namely, the star Xi Ursæ Majoris. This remarkable pair was discovered by Sir William Herschel in 1780, and as the period of revolution is about sixty-one years, a considerable portion of the ellipse had been described in 1830, when it was attacked by Savary.

The binary star with the shortest period known at present seems to be the fourth magnitude star Kappa Pegasi. It was discovered as a wide double star by Sir William Herschel in 1786, the companion star being of the ninth magnitude. In August, 1880, Mr. Burnham, the famous American double star observer, examining the star with the 18½-inch refractor of the Dearborn Observatory, found the brighter star to be a very close double, with a distance between the components of only a quarter of a second of arc. A few years' observations showed that this pair were in rapid motion round each other (about eleven years).

Another binary star, with a period of about the same length, is Delta Equulei, which was discovered to be a close double by Otto Struve in 1851. Next in order of shortness of period comes the southern binary star Zeta Sagittarii, for which an orbit was first computed in the year 1886 by the present writer. The orbit of this star will, I think, require still further[202] revision, but the period of about eighteen years is probably not far from the truth.

Another remarkably rapid binary star is 85 Pegasi. Next in order of rapidity of motion we have the southern binary star 9 Argûs.

The star 42 Comæ Berenices has a period of about 25¾ years, according to Otto Struve. The orbit is remarkable from the fact that its plane passes through, or nearly through, the earth, and is, therefore, projected into a straight line, the companion star oscillating backward and forward on each side of its primary.

The star Beta Delphini—the most southern of the four stars in the "Dolphin's Rhomb"—is also a fast-moving binary, discovered by Burnham in 1873. Burnham thinks the period will prove to be about twenty-eight years. The spectrum of the light of Beta Delphini is similar to that of our sun, so that the two bodies should be comparable in intrinsic brilliancy.

Another remarkable binary star with a comparatively short period is Zeta Herculis. This pair have now performed three complete revolutions since their discovery in 1782 by Sir William Herschel. Several orbits have been computed, but Dr. See's period of thirty-five years is probably the best. The companion is, however, rather faint, being only 6½ magnitude, while the primary star is of the third.

In the case of the binary star, Eta Coronæ Borealis, it was, some forty years ago, uncertain whether its period was forty-three or sixty-six years, but now that two complete revolutions have been performed[203] since its discovery by Sir William Herschel in 1781, the question has been finally decided in favor of the shorter period.

The brilliant star Sirius is also an interesting binary star. The companion, which is relatively very faint—about tenth magnitude—was discovered by Alvan Clark in 1862. The existence of some such disturbing body was previously suspected by astronomers, owing to observed irregularities in the proper motion of Sirius. Several orbits, giving periods of about fifty years, have been computed. The great brilliancy of Sirius, the brightest star in the heavens, naturally suggests a sun of great size. Recent investigations do not favor this idea. Its spectrum is, however, of the first type, and the star is therefore not comparable with the sun in brilliancy. The above result would indicate that stars of the first, or Sirian type, are intrinsically brighter than our sun.

Sirius is about eleven magnitudes brighter than its faint companion. This makes the light of Sirius about 25,000 times the light of the small star. The two bodies must, therefore, be differently constituted, and, indeed, the companion must be nearly a dark body. If Sirius has any planets revolving round it—like those of our solar system—they must forever remain invisible in our largest telescopes. This remark, of course, applies to all the fixed stars, single and double. They may possibly have attendant families of planets, like our sun, but if so, the fact can never be ascertained by direct observation.

The star Zeta Cancri is a well-known triple star, the close pair revolving in a period of about sixty[204] years. Nearly two revolutions have now been completed since its discovery by Sir William Herschel in 1781. All three stars probably form a connected system, but the motion of the third star round the binary pair is very slow and irregular. Drawing of binary star Fig. 18.—System of the Double Sun Alpha Centauri

Another interesting binary star is Xi Ursæ Majoris. As already stated, this was the first pair for which an orbit was computed. More than a complete revolution has now been performed since its discovery by Sir William Herschel in 1780. The period has, therefore, been well determined, and seems to be about sixty years.

The bright southern star, Alpha Centauri, the nearest of all the fixed stars to the earth, so far as[205] is known at present, is also a remarkable binary star. It seems to have been first noticed as a double star by Richaud in 1690.

Assuming my value of the sun's stellar magnitude (about 27), I find that the sun, if placed at the distance of Alpha Centauri, would appear of about the same brightness as the star does to us. As, according to Professor Pickering, the spectrum of Alpha Centauri is

of the second or solar type, it would seem that in mass, brightness, and physical condition the star closely resembles our sun.

We next come to another very interesting binary star, known to astronomers as 70 Ophiuchi. It is a very fine double star, the magnitudes of the components being about four and six, and the colors yellow and orange. More than a complete revolution has now been described by the components since its discovery by Sir William Herschel in 1779. Placed at the distance indicated by Krüger's parallax, I find that our sun would be reduced to a star of about magnitude 3½, which shows that the sun and star are of about equal brightness. The spectrum is of the solar type, according to Vogel.

A very famous binary star is that known to astronomers as Gamma Virginis. Its history is a very interesting one. It lies close to the celestial equator, about one degree to the south and about fifteen degrees to the northwest of the bright star Spica (Alpha of the same constellation), with which it forms the stem of a Y-shaped figure formed by the brightest stars of the constellation Virgo, or the Virgin, Gamma being at the junction of the two upper[206] branches. The brightness of Gamma Virginis is a little greater than an average star of the third magnitude. Variation of light has, however, been suspected in one or both components. The Persian astronomer, Al-Sûfi, in his description of the heavens, written in the Tenth Century, rates it of the third magnitude, and describes it as "the third of the stars of al-auvâ, which is a mansion of the moon," the first and second stars of this "mansion" being Beta and Eta Virginis, the fourth star Delta, and the fifth Epsilon, these five stars forming the two upper branches of the Y-shaped figure above referred to. Gamma was called Zawiyah-al-auvâ, "the corner of the barkers!" perhaps from its position in the figure, which formed the thirteenth Lunar Mansion of the old astrologers. It was also called Porrima and Postvarta in the old calendars. The fact that Gamma Virginis really consists of two stars very close together seems to have been discovered by the famous astronomer, Bradley, in 1718. The rapid decrease in the apparent distance from 1780-1834 indicated that the apparent orbit is very elongated, and that possibly the two stars might "close up" altogether, and appear as a single star even in telescopes of considerable power. This actually occurred in the year 1836, or, at least, the stars were then so close together that the most powerful telescopes of that day failed to show Gamma Virginis as anything but a single star. Of course, it would not have been beyond the reach of the giant telescopes of our day. From the year 1836 the pair began to open out again.

Another interesting binary star is Eta Cassiopeiæ.[207] Periods ranging from 149 to 222½ years have been found by different computers. The most recent computation makes it about 196 years.

The bright star Gamma Leonis, situated in the well-known "Sickle in Leo," is also a binary star, but only a small portion of the orbit has been described since its discovery by Sir William Herschel in 1782. Dr. Doberck finds a period of 407 years. It is remarkable for its very high "relative brightness." This pair forms a fine object for a small telescope.

The star known as 12 Lyncis is a triple star, the components being 5, 6, and 7½ magnitude. The close pair forms a binary system, for which an orbit has been computed by the present writer, who finds a period of about 486 years. Sir John Herschel predicted in 1823 that the angular motion of the pair would "bring the three stars into a straight line in 57 years." This prediction was fulfilled in 1887, when measures by Tarrant showed that the stars were then exactly in a straight line.

The bright star Castor is a famous double star, and has been known since the year 1718, when it was observed by Bradley and Pond. It was also observed by Maskelyne in 1759, and frequently by Sir William Herschel from 1799 to 1803. Numerous orbits have been computed, with periods ranging from 199 years by Mädler and 1,001 years by Doberck. I find that the mass of the system of Castor is only 1/19th of the sun's mass, a result which would imply that the components are masses of glowing gas! Dr. Bélopolsky has found, with the spectroscope,[208] that the brighter component is a close binary star with a dark companion, like Algol. The period of revolution is about three days, and the relative orbital velocity about 20¾ miles a second. Dr. Bélopolsky's observations show that the system is receding from the earth at the rate of about 4½ miles per second.

With reference to the colors of the components of binary stars, the following relation between color and relative brightness has been established:

(1) When the magnitudes of the components are equal, or approaching equality, the colors are generally the same, or similar.

(2) When the magnitudes of the components differ considerably, there is also a considerable difference in color.

A new class of binary stars has been discovered within the last few years by means of the spectroscope. These have been called "spectroscopic binaries," and the brighter component of Castor, referred to above, is an example of the class. They are supposed to consist of two component stars, so close together that the highest powers of the largest telescopes fail to show them as anything but single stars. Indeed, the velocities indicated by the spectroscope show that they must be so close that the components must

forever remain invisible by the most powerful telescopes which could ever be constructed by man. In some of these remarkable objects, the doubling of the spectral lines indicates that the components are both bright bodies, but in others, as in Algol, the lines are merely shifted from their normal position, not doubled, thus denoting that one of the components is[209] a dark body. In either case, the motion in the line of sight can be measured by the spectroscope, and we can, therefore, calculate the actual dimensions of the system in miles, and thence its mass in terms of the sun's mass, although the star's distance from the earth remains unknown. Judging, however, from the brightness of the star, and the character of its spectrum, we can make an estimate of its probable distance from the earth.

The bright star Spica has also been found by the spectroscope to be a close binary star. Vogel finds a period of four days with a distance between the components of about 6¼ millions of miles, and assuming that the components have equal mass and are moving in a circular orbit, he finds the mass of the system about 2.6 times the mass of our sun. In addition to its orbital motion, Vogel finds that Spica is approaching the sun at the rate of over nine miles per second.

To ordinary observers, the light of the stars seems to be constant. Even to those who are familiar with the constellations, the stars appear to maintain their relative brilliancy unchanged. To a great extent this is, of course, true; the great majority of the stars remaining of the same brightness from day to day, and from year to year. There are, however, numerous exceptions to this rule. Many of the stars, when carefully watched, are found to fluctuate in their light, being sometimes brighter and sometimes fainter. These are known as "variable stars"—one of the most interesting class of objects in the heavens. Some of these have been known for a great number[210] of years, and their variations having been carefully watched, the laws governing their light changes have been well determined.

We will first consider the variable stars with long periods of variation, as these generally show the largest fluctuations of light. Among these, the first star in which variation of light seems to have been noticed is the extraordinary object, Omicron Ceti, popularly known as Mira, or the "wonderful" star. It appears to have been first noticed by David Fabricius in the year 1596. He observed that the star now called Omicron, in the constellation Cetus, was of the third magnitude on April 13 of that year, and that in the following year it had disappeared. Bayer saw it again in 1603, when forming his maps of the constellations, and assigned to it the Greek letter Omicron, but does not seem to have noticed the fact that it was the same star which had been observed by Fabricius seven years previously. No further attention seems to have been paid to it until 1638 and 1639, when it was observed at Francker by Professor Phocylides Holwarda to be of the third magnitude in December, 1638, invisible in the following summer, and again visible in October, 1639. From 1648 to 1662 it was carefully observed by Hevelius, and in subsequent years by several observers. Its variations are now regularly followed from year to year, and it forms one of the most interesting objects of its kind in the heavens. Its light varies from about the second magnitude to the ninth, but its brightness at maximum is variable to a considerable extent.

[211]

Perhaps the long period variable star next in order of interest—at least to observers in the Northern Hemisphere—is that known as Chi Cygni. It was discovered by Kirch in 1686. The star varies at maximum from 4 to 6½ magnitude, and at the minimum it sinks to below the thirteenth magnitude. At some maxima, therefore, it is easily visible to the naked eye, and at others it is just below the limit of ordinary vision. At the maximum of 1847, it was visible to the naked eye for a period of 97 days. The average period is about 406 days; but according to Schönfeld—a well-known authority on the variables—observations indicate a small lengthening of the period. Chi Cygni is said to be "strikingly variable in color." Espin's observations in different years show it "sometimes quite red, at others only pale orange-red." In the spectroscope, its light shows a splendid spectrum of the third type (or banded spectrum, very characteristic of these long period variables), in which bright lines were observed by Espin in May, 1889.

R Leonis is another remarkable variable star, which is sometimes visible to the naked eye at maximum. It lies closely south of the star known as 19 Leonis. It was discovered by Koch in 1782. At the maximum, its brightness varies from 5.2 to 7 magnitude, and at minimum it fades to about the tenth magnitude. The mean period is about 313 days. The star is red in all phases of its light, and forms a fine telescopic object. Close to it are two small stars, which form, with the variable, an isosceles triangle.

There is a very remarkable variable star in the[212] Southern Hemisphere known as Eta Argûs. It lies in the midst of the great nebula in Argo, and the history of its fluctuations in light is very interesting. Observed by Halley in 1677 as a star of the fourth magnitude, it was seen of the second magnitude by Lacaille in 1751. After this, it must have again faded, for Burchell found it of only the fourth magnitude from 1811 to 1815. From 1822 to 1826 it was again of the second magnitude, as observed by Fallows

and Brisbane; but on February 1, 1827, it was estimated of the first magnitude by Burchell. It then faded again, for on February 29, 1828, Burchell found it of the second magnitude. From 1829 to 1833 Johnson and Taylor rated it of the second magnitude; and it was still of this magnitude, or a little brighter, when Sir John Herschel commenced his observations at the Cape of Good Hope in 1834. It does not seem to have varied much in brightness from that time until December, 1837, when Herschel was astonished to find its light "nearly tripled." He says: "It very decidedly surpassed Procyon, which was about the same altitude, and was far superior to Aldebaran. It exceeded Alpha Orionis, and the only star (Sirius and Canopus excepted) which could at all be compared with it was Rigel."

From this time its light continued to increase. On the 28th December it was far superior to Rigel, and could only be compared with Alpha Centauri, which it equaled, having the advantage of altitude, but fell somewhat short of it as the altitudes approached equality. The maximum of brightness[213] seems to have been obtained about the 2d of January, 1838, on which night, both stars being high and the sky clear and pure, it was judged to be very nearly matched, indeed, with Alpha Centauri. In 1843 it again increased in brightness, and in April of that year it was observed by Maclear to be brighter than Canopus, and nearly equal to Sirius! It then faded slightly, but seems to have remained nearly as bright as Canopus until February, 1850, since which time its brilliancy gradually decreased. It was still of the first magnitude in 1856, according to Abbott, but was rated a little below the second magnitude by Powell in 1858. Tebbutt found it of the third magnitude in 1860; Abbott a little below the fourth in 1861. Ellery rated it fifth magnitude in 1863, and Tebbutt sixth magnitude in 1867. In 1874 it was estimated 6.8 magnitude at Cordoba, and only 7.4 in November, 1878. Tebbutt's observations from 1877-86 show that it did not rise above the seventh magnitude in those years, and in March, 1886, it was rated 7.6 magnitude by Finlay at the Cape of Good Hope. This seems to have been the minimum of light, for in May, 1888, Tebbutt found that it "had increased fully half a magnitude" since April, 1887. The star is very reddish in color.

We will now consider the variables of short period, which are particularly interesting objects, owing to the comparative rapidity of their light changes. The periods vary in length from about 17¼ days down to a few hours. Perhaps the most interesting of these short period variables, at least to the amateur observer, is the star Beta Lyræ, which[214] is easily visible to the naked eye in all phases of its light. It can be readily identified, as it is the nearest bright star to the south of the brilliant Vega, and one of two stars of nearly the same magnitude, the second being Gamma Lyræ. The variability of Beta Lyræ was discovered by Goodricke in the year 1784. The period is about 12 days, 21 hours, 46 minutes, 58 seconds. Recent observations with the spectroscope indicate that the star is a very close double or "spectroscopic binary," although it does not seem certain that an actual eclipse of one component by the other takes place, as in the case of Algol. Bright lines were detected in the star's spectrum by Secchi so far back as 1866. In 1883 M. Von Gothard noticed that the appearance of these bright lines varied in appearance, and from an examination of photographs taken at Harvard Observatory in 1891, Mrs. Fleming found displacements of bright and dark lines in a double spectrum, the period of which agreed fairly well with that of the star's light changes.

Another interesting star of short period is Delta Cephei, which is one of three stars forming an isosceles triangle a little to the west of Cassiopeia's Chair, the variable being at the vertex of the triangle, and the nearest of the three to Cassiopeia. Its variability was also discovered by Goodricke in 1784. It varies from 3.7 to 4.9 magnitude, with a period of 5 days, 8 hours, 47 minutes, 40 seconds. The amount of the variation is, therefore, the same as in the case of Algol, the star's light at maximum being about three times its light at minimum. The observations[215] also show that Delta Cephei is approaching the earth at the rate of about 8¾ miles a second. The color of the star is yellow, and it has a distant bluish companion of about the fifth magnitude, which may possibly have some physical connection with the brighter star, as both stars have a common proper motion through space.

Another remarkable star of short period is Eta Aquilæ, the variability of which was discovered by Pigott in 1784. It varies from magnitude 3.5 to 4.7, with a period of 7 days, 4 hours, 14 minutes, but Schönfeld found marked deviations from a uniform period. Its color is yellow, and its spectrum, like that of Delta Cephei, of the second or solar type.

A remarkable variable star of short period was discovered in 1888 by Mr. Paul in the southern constellation Antlia. It varies from magnitude 6.7 to 7.3, with the wonderfully short period of 7 hours, 46 minutes, 48 seconds, all the light changes being gone through no less than three times in twenty-four hours! It was for some years believed that the variation was of the Algol type, but recent measures made at the Harvard College Observatory show that it belongs to the same class as Delta Cephei and Eta Aquilæ.

A telescopic variable with a wonderfully short period was discovered by Chandler in 1894. It lies a little to the west of the star Gamma Pegasi, and has been designated U Pegasi. It varies from magnitude 8.9 to 9.7, and was first supposed to be of the Algol type with a period of about two days, but further observations showed that the period was[216] much shorter, and only 5 hours, 31 minutes, 9 seconds. The remarkable rapidity of its light changes, which are gone through four times in less than twenty-four hours,

make this remarkable star a most interesting object. Possibly there may be other stars in the heavens with a similar rapidity of variation which have hitherto escaped detection.

Unlike the variable stars of long period which seemed scattered indifferently over the surface of the heavens, the great majority of the short period variables are found in a zone which nearly coincides with the course of the Milky Way. The most notable exceptions to this rule are W Virginis with the comparatively long period of 17¼ days, and U Pegasi, above described, which has the shortest known period of all the variable stars. Another peculiarity is that most of them are situated in what may be called the following hemisphere, that is between 12 hours and 24 hours of right ascension. The most remarkable exception to this rule is Zeta Geminorum.

Algol, or Beta Persei, is a famous variable star, and the typical star of the class to which it belongs. Its name, Algol, is derived from a Persian word, meaning the “demon,” which suggests that the ancient astronomers may have detected some peculiarity in its behavior. The real discovery of its variation was, however, made by Montanari in 1667, and his observations were confirmed by Maraldi in 1692. Its fluctuations of light were also noticed by Kirch and Palitzsch, but the true character of its variations was first determined by the English astronomer, Goodricke, in 1782. Its fluctuations of[217] light are very curious and interesting. Shining with a constant, or nearly constant, brightness for a period of about 59 hours as a star of a little less than the second magnitude, it suddenly begins to diminish in brightness, and in about 4½ hours it is reduced to a star of about magnitude 3½. In other words, its light is reduced to about one-third of its normal brightness. If we suppose three candles placed side by side at such a distance that their combined light is merged into one, and equal to the usual brightness of Algol, then, if two of these candles are extinguished, the remaining candle will represent the light of Algol at its minimum brilliancy. The star remains at its minimum, or faintest, for only about 15 minutes. It then begins to increase, and in about 5 hours recovers its normal brightness, all the light changes being gone through in a period of about 10 hours out of nearly 69 hours, which elapse between successive minima. These curious changes take place with great regularity, and the exact hour at which a minimum of light may be expected can be predicted with as much certainty as an eclipse of the sun.

Goodricke, comparing his own observations with one made by Flamsteed in the year 1696, found the period from minimum to minimum to be 2 days, 20 hours, 48 minutes, 59½ seconds, and he came to the conclusion that the diminution in the light of the star is probably due to a partial eclipse by “a large body revolving round Algol.” This hypothesis was fully confirmed in the years 1888-89 by Professor Vogel with the spectroscope. As no close[218] companion to Algol is visible in the largest telescopes, we must conclude that either the satellite is a dark body, or else so close to the primary that no telescope could show it. Now, if the diminution in Algol’s light is due to a dark body revolving round it, and periodically coming between us and the bright star, it follows that both components will be in motion, and both will revolve round the common centre of gravity of the pair. A little before a minimum of light takes place, the dark companion should therefore be approaching the eye, and, consequently, the bright companion will be receding. During the minimum there will be no apparent motion in the line of sight, as the motion of both bodies will be at right angles to the visual ray. After the minimum is over, the motion of the two bodies will be reversed, the bright one approaching the eye, and the dark one receding. Now, this is exactly what Vogel found. Before the diminution in the light of Algol begins, the spectroscope showed that the star is receding from the earth and after the minimum that it is approaching the eye. That the companion is dark and not bright, like the primary, is evident from the fact that the spectral lines are merely shifted from their normal position and not doubled, as would be the case were both components bright, as in the case of some of the “spectroscopic binaries”—for example, Beta Aurigæ. Vogel found that before the minimum of light, Algol is receding from the earth with the velocity of 24½ miles a second, and after the minimum it is approaching at the rate of 28½ miles a second. The difference between the observed[219] velocities indicates that the system is approaching the earth with a velocity of about 2 miles a second. Knowing, then, the orbital velocity, which is evidently about 26½ miles a second, and assuming the orbit to be circular, it is easy, with the observed period of revolution, or the period of light variation, to calculate the diameter of the orbit in miles, although the star’s distance from the earth remains unknown. Further, comparing its period of revolution and the dimensions of the orbit with that of the earth round the sun, it is easy to calculate, by Kepler’s third law of motion, the mass of the system in terms of the sun’s mass, and the probable size of the component bodies. Calculating in this way, Vogel computes that the diameter of Algol is about 1,061,000 miles, and that of the dark companion 830,300 miles, with a distance between their centres of 3,230,000 miles, and a combined mass equal to two-thirds of the sun’s mass, the mass of Algol being four-ninths, and that of the companion two-ninths, of the mass of the sun. Taking the diameter of the sun as 866,000 miles, and its density as 1.44 (water being unity), I find that the above dimensions give a mean density for the components of Algol of about one-third that of water, so that the components are probably gaseous bodies, as Hall has already concluded. Sun spot Portion of the Sun’s Surface. Sunspot nearly 60,000 Miles Across

It is a curious fact that Al-Sûfi, the Persian astronomer, in his Description of the Heavens, written in the Tenth Century, speaks distinctly of Algol as a red star (étoile, brillant; d'un éclat, rouge), while at present it is white or at the most of a yellow[220] color. A similar change of color is supposed to have taken place in the case of Sirius, but the change in Algol seems more certain, as Al-Sûfi's descriptions are generally most accurate and reliable.

Stars of the Algol type of variable are very rare objects, only a dozen or so having been hitherto discovered in the whole heavens. Those visible to the naked eye, when at their normal brightness, are: Algol, Lambda Tauri, Delta Libræ, R Canis Majoris, and U Ophiuchi.

A remarkable peculiarity about the variable stars in general is that none of them has any considerable proper motion. As a large proper motion is generally considered to indicate proximity to the earth, we may conclude, with great probability, that the variable stars, as a rule, lie at a great distance from our system. In other words, it appears that the sun does not lie in a region of variable stars, and, with the exception of Alpha Cassiopeiæ and Alpha Herculis, a measurable parallax has not yet been found, so far as I know, for any known variable star.

We now come to the interesting and mysterious class of objects known as "new" or "temporary" stars. These phenomena are of very rare occurrence, and but few undoubted examples of the class are recorded in the annals of astronomy. Possibly in some cases they have been merely variable stars, of irregular period and fitful variability; but others may have been due to a real catastrophe, such as the collision of two dark bodies in space, or, possibly, the passage of a bright or dark body through a gaseous nebula.

[221]

The earliest temporary star of which we have any reliable information seems to be one which is recorded in the Chinese annals of Ma-tuan-lin, as having appeared in the year 134 B. C. in the constellation Scorpio. Its position seems to have been somewhere between the stars Beta and Rho of Scorpio. Pliny informs us that it was the sudden appearance of a new star which induced the famous astronomer Hipparchus to form his catalogue of stars, the first ever constructed. As the date of Hipparchus's catalogue is 125 B. C., it seems highly probable that the new star referred to by Pliny was the same as that recorded by the Chinese astronomer as having appeared nine years previously.

A new star is said to have appeared in the year 76 B. C. between the stars Alpha and Delta in the Plow, but the accounts are vague.

In 101 A. D., a small "yellowish-blue" star is said to have appeared in the "sickle" in Leo, but its exact position is not known. In 107 A. D., a new star is mentioned near Delta, Epsilon and Eta in Canis Major, three bright stars southeast of Sirius. In 123 A. D., another new star is recorded by Ma-tuan-lin to have appeared between Alpha Herculis and Alpha Ophiuchi.

The Chinese annals record that on December 10, 173 A. D., a brilliant star appeared between Alpha and Beta Centauri in the Southern Hemisphere. It remained visible for eight months, and is described as resembling "a large bamboo mat!"—a curious description. There is at present, close to the spot indicated, a known variable star—R Centauri—of[222] which the period seems to be long and the variation of light irregular. Possibly an unusually bright maximum of this variable star formed the star of the Chinese annals, or perhaps the variable star is the remnant of the outburst which took place in the First Century. The variable is a very reddish star, and at present varies from about the sixth to the tenth magnitude.

A new star is recorded in the year 386 A. D. as having appeared between Lambda and Phi Sagittarii. Near the position indicated, Flamsteed observed a star, No. 65 of his catalogue, which is now missing; and it has been conjectured that the star seen by Flamsteed may possibly have been a return of the star mentioned in the Chinese annals.

Cuspianus relates that a star as bright as Venus appeared near Altair in 389 A. D., during the reign of the Emperor Honorius, and that he had himself seen it. There is some doubt, however, about the exact date, as other accounts give the year 388 or 398. The star seems to have disappeared in about three weeks.

In the year 393 A. D., another strange star is recorded in the tail of Scorpio. An extraordinary star is said to have been seen near Alpha Crateris in 561 A. D. Here again a known variable and red star—R Crateris—is close to the position indicated by the ancient records.

The Chinese annals record a new star in 829 A. D., somewhere in the vicinity of the bright star Procyon, and in this locality there are several known variable stars.

[223]

The Bohemian astronomer, Cyprianus Leoviticus, mentions the appearance of new stars in Cassiopeia in the years 945 A. D. and 1264, and it has been conjectured that perhaps these were apparitions of Tycho Brahe's famous star of 1572 (to be presently described), forming a variable star with a period of over 300 years. Lynn and Sadler, however, have shown that the supposed stars of 945 and 1264 were, in all probability, comets.

Extraordinary stars are recorded near Zeta Sagittarii in 1011 A. D., near Mu Scorpii in 1203, and near Pi Scorpii on July 1, 1584. It is remarkable how many of these objects seem to have appeared in this portion of the heavens.

A very brilliant star is mentioned by Hepidannus as having appeared in Aries in May, 1012. He describes it as "dazzling the eye." Other temporary stars are mentioned in 1054 A. D., near Zeta Tauri, and in 1139 near Kappa Virginis; but the accounts of these are very vague, and it seems by no means certain that they were really new stars.

No possible doubt, however, can be entertained with reference to the appearance of the object which suddenly blazed out in Cassiopeia's Chair in November, 1572. It was called the "Pilgrim Star," and was observed by the famous astronomer, Tycho Brahe, who has left us a very elaborate account of its appearance, position, etc. Although usually spoken of as Tycho Brahe's star, it seems to have been really discovered by Cornelius Gemma on the evening of November 9. That its appearance was very sudden may be inferred from Cornelius Gemma's[224] statement that it was not visible on the preceding night in a clear sky. Tycho Brahe's attention was first attracted to it on November 11. His description of the new star is as follows—as quoted by Humboldt: "On my return to the Danish islands from my travels in Germany, I resided for some time with my uncle, Steno Bille, in the old and pleasantly situated monastery of Herritzwadt, and here I made it a practice not to leave my chemical laboratory until the evening. Raising my eyes, as usual, during one of my walks, to the well-known vault of heaven, I observed with indescribable astonishment, near the zenith in Cassiopeia, a radiant fixed star of a magnitude never before seen. In my amazement, I doubted the evidence of my senses. However, to convince myself that it was no illusion, and to have the testimony of others, I summoned my assistants from the laboratory, and inquired of them, and of all the country people that passed by, if they also observed the star that had thus suddenly burst forth. I subsequently heard that in Germany, wagoners and other common people first called the attention of astronomers to this great phenomenon in the heavens—a circumstance which, as in the case of non-predicted comets, furnished fresh occasion for the usual raillery at the expense of the learned. This new star I found to be without a tail, not surrounded by any nebula, and perfectly like all other fixed stars, with the exception that it scintillated more strongly than stars of the first magnitude. Its brightness was greater than that of Sirius, Alpha Lyræ, or Jupiter. For splendor, it was only comparable to Venus when[225] nearest to earth (that is, when only a quarter of her disk is illuminated). Those gifted with keen sight could, when the air was clear, discern the new star in the daytime, and even at noon. At night, when the sky was overcast, so that all other stars were hidden, it was often visible through the clouds, if they were not very dense (nubes non admodum densas). Its distances from the nearest stars of Cassiopeia, which throughout the whole of the following year I measured with great care, convinced me of its perfect immobility. Already in December, 1572, its brilliancy began to diminish, and the star gradually resembled Jupiter, but by January, 1573, it had become less bright than that planet. Toward the month of November the new star was not brighter than the eleventh in the lower part of Cassiopeia's Chair. The transition to the fifth and sixth magnitudes took place between December, 1573, and February, 1574. In the following month the new star disappeared, and, after having shone seventeen months, was no longer discernible to the naked eye." (The telescope was not invented until thirty-seven years afterward.) Humboldt adds: "At its first appearance, as long as it had the brilliancy of Venus and Jupiter, it was for two months white, and then passed through yellow into red. In the spring of 1573, Tycho Brahe compared it to Mars; afterward he thought it nearly resembled Betelgeuse, the star in the right shoulder of Orion. The color for the most part was like the red tint of Aldebaran. In the spring of 1573, and especially in May, its white color returned (albedinam quandam sublividam induebat,[226] qualis Saturni stellæ subesse videtur). So it remained in January, 1574; being, up to the time of its entire disappearance in the month of March, 1574, of the fifth magnitude, and white, but of a duller whiteness, and exhibiting a remarkably strong scintillation in proportion to its faintness."

Ma-tuan-lin speaks of a star in 1578 "as large as the sun" (!) but does not state its position.

The star known as P (34) Cygni is sometimes spoken of as a "Nova," or new star; but it is still visible to the naked eye as a star of the fifth magnitude. It was observed of the third magnitude by Jansen in 1600 and by Kepler in 1602. After the year 1619 it appears

to have diminished in brightness, and is said to have vanished in 1621; but it may merely have become too faint to be seen with the naked eye. It was again observed of the third magnitude by Dominique Cassini in 1655, and it afterward disappeared. It was again seen by Hevelius in November, 1655. In 1667, 1682, and 1715 it is recorded as of the sixth magnitude, and there is no further record of any marked increase in its light. A period of about 18 years was assumed by Pigott; but this is now disproved, and it seems probable that the star is a variable of irregular period and fitful variability, and not, properly speaking, a temporary star. Its present color is yellow, and bright lines have been seen in its spectrum.

A new star of the third magnitude was observed near Beta Cygni by the Carthusian monk Anthelmus in 1670. It remained visible for about two years, and is said to have increased and diminished several[227] times before its final disappearance. Schönfeld computed its exact position from observations made by Hevelius and Picard. Quite close to the spot indicated, a star of the eleventh magnitude has been observed at the Greenwich Observatory, and fluctuations of light were suspected in this small star by Hind and others.

A very remarkable star, sometimes called the “Blaze Star,” suddenly appeared in Corona Borealis, in May, 1866. It was first seen by the late Mr. Birmingham, at Tuam, Ireland, about midnight on the evening of May 12, when it was of the second magnitude, and equal to Alphecca, “the gem of the coronet.” Its appearance must have been very sudden, for Schmidt, the Director of the Athens Observatory, stated that he was observing the constellation on the same evening, about two and one-half hours previous to Birmingham’s discovery, and observed nothing unusual. He was certain that no star, of even the fifth magnitude, could possibly have escaped his notice. On the following night it was seen by several observers in different parts of the world.

A remarkable and very interesting temporary star was discovered in 1892 in the constellation Auriga.

It is a remarkable fact that the great majority of the temporary stars appeared in or near the Milky Way. The chief exceptions to this rule are: the star of 76 B. C., in the Plow, the star recorded by Hepidannus in Aries, 1012 A. D., and the “Blaze Star” of 1866 in Corona Borealis.

[228] A WORLD ON FIRE—NOVA PERSEI.—Alexander W. Roberts

In the small hours of the morning of 22d February, 1901, Dr. Anderson of Bonnington, Edinburgh, saw a bright star shining in the constellation of Perseus, where he knew no such star was ever seen before. The circumstances connected with this discovery afford another striking instance of how Nature keeps her secrets for her true amateur, using the word in its highest sense.

The evening of 21st February was cloudy, and nine out of ten astronomers would have gone to bed when there seemed little prospect of the night clearing; but Dr. Anderson was the tenth man. At twenty minutes to three in the morning the clouds rolled away from over the old gray Scottish capital, and the trained eye of the patient observer saw right in the heart of Perseus a new star. Never before had its light, blue-white, like an unpolished diamond, shone down on this strange earth of ours.

Next day the news of the wonderful discovery was flashed to all the great observatories of the world, and telescopes and spectroscopes, cameras and photometers, were directed toward the strange phenomenon, and by testing, measuring, examining, sought to wrest its secrets from it.

Much is still a mystery; but what has been ascertained during the period that the rhythm of its light-waves beat upon our shores is of great interest and importance as bearing directly on the life-history[229] of each individual star in the heavens, and of our own sun and planet among them.

The first and simplest question that arises for settlement is the date when the new star blazed forth in our terrestrial sky. The curious reader will notice the reservation: in our terrestrial sky. When the star actually burst forth into resplendent light is another matter, as we shall discover later on. It was certainly before Dr. Anderson was born, and probably before another Scotsman—Ferguson by name—combined, like many another sage, counting and watching sheep with counting and watching stars.

With regard to the date of the appearance in our sky of the new star, Nova Persei, as it is called in astronomical literature, when Dr. Anderson discovered it at twenty minutes to three o’clock on the morning of 22d February, it was bright enough to be straightway evident to a trained astronomer. In these later days of strenuous scientific activities every portion of the sky is constantly being examined and charted, and no sooner was the discovery of Nova Persei announced than a searching of records began, in order to ascertain if, at any time, the star had ever been seen before. Drawing of Perseus region Fig. 19.—Chart Showing Position of Nova

Persei

It so chanced that on the evenings of 18th and 19th February two photographs of the very spot where three days later the new star appeared were taken at Harvard Observatory. On neither of these photographs is there the slightest evidence of the star's existence. It was, therefore, on these dates non-existent so far as our earth was concerned. On the evening of 20th February a well-known English observer,[230] Mr. Stanley Williams, had also taken a photograph of the same portion of the sky; and again there was no trace of the star. Mr. Williams's photograph was taken twenty-eight hours before Dr. Anderson saw it. Still more strange is the fact that on the evening of 21st February three observers on the Continent testify that they had the constellation Perseus under[231] observation from seven o'clock to eleven, and had the new star then been visible they could not have failed to see it. The star, therefore, blazed out some time between eleven o'clock and three on the night of its discovery.

Now, what does this mean? It means this: that by some cause a star, quite dark before, or so faint that it could not be seen even by means of a powerful telescope, in a few hours, or perhaps in a few minutes, blazed forth as a star of conspicuous brightness. In this brief space of time a dark and probably chill globe became a seething mass of fire, a million times hotter than it was before. Fierce, fervent heat lit up the orb with a glow that reached from rim to rim of the stellar universe. We have here a catastrophe that goes beyond our wildest conceptions: the conflagration of a world, the ruin of a star. What guarantee have we for an assumption of this kind? What of certitude is there in our vision of such a Day of Doom for any part of our universe? Let us consider the salient facts regarding the recent changes in the appearance and structure of this star. We shall relate only those facts that are beyond controversy, as far as our present knowledge goes.

Nova Persei did not reach its maximum brightness till the evening of 25th February, when it was probably the most conspicuous object in the midnight sky. It was then at least six times brighter than at the time of its discovery. After this date it began to wane slowly. At intervals there were spurts of brightness lasting for two or three days, as if the fires had not exhausted themselves. On the whole,[232] however, the light of the star waned, and by the end of the year its enfeebled light was just bright enough to be evident to the naked eye; twelve months after its appearance it could only be seen with the aid of a telescope.

Now, one of the most powerful instruments of research in the new astronomy is the spectroscope. It takes hold of the rays of light that come to us from a star, and makes these rays reveal the condition of things in the world they come from. One of the spectroscopes turned on the new star in Perseus was Professor Copeland's magnificent instrument at Blackford Hill Observatory, Edinburgh. Professor Copeland described the new star as "a feebly developed" sun. As the star, however, increased in brightness the spectroscope chronicled the fact that great physical changes were taking place in its composition and structure. The star soon ceased to be a feebly developed sun, for development had gone on apace with the increase of light. Round the solid or semi-molten mass there was rapidly aggregating an ocean of fiery gases, probably thrown up from the nucleus.

Put simply, Nova Persei, for long ages a cold, dark, solid globe, was in the brief space of a few days transformed from circumference to core into a luminous, heated gaseous sphere. By what chance or circumstance this vast change came about may be inquired into later on. We only note here that this was the story spelled out by those skilled in deciphering the observations recorded by the spectroscope. In July, 1901, Professor Pickering of Harvard[233] Observatory announced that the star had become a nebula; that, indeed, its once solid globe had practically dissolved into thinnest air. Not only had its elements become molten with fervent heat, but they had become transformed into shimmering wisps of matter more diaphanous than a gossamer web.

Everything connected with the history of this star is of exceptional interest; but all that had already been ascertained was completely overshadowed by the astonishing discovery made in November, 1902, that nebulous prominences were observed darting out from the star with a velocity of at least 100,000 miles every second of time. These astonishing changes have been confirmed at the two great American observatories, the Yerkes and the Lick.

Whence and how had destruction come upon this particular star? At one hour the star is dark, cold, solid. A few hours later this dark, solid, cold body is a blazing world, its solid mass blown apparently into countless fragments; from every fragment, big or little, there pour streams of fiery vapor; for millions of miles round the star there is a whirlpool of fire, a tempest of flame; and from end to end of this great universe of ours the brightness of the burning star pulsates. Three explanations have been given.

The one that naturally arises in our mind is that it was struck by another star. Two worlds, each moving at the rate of twenty miles a second, come into collision, and the result is the annihilation of both. The force of their impact, changed into heat, drives their elements into vapor. Such a catastrophe is quite possible in a universe like ours, where stars[234] and worlds, millions and millions in number, sweep down the great avenues of space with a velocity far beyond our comprehension.

We take it that when the crack of doom comes to this earth of ours it will be in this fashion. Some great dark star will strike our sun fair and square, and then in the twinkling of an eye, before the inhabitants of earth know what has taken place, sun and moon and planet will be wrapped up and dissolved in an atmosphere of fire.

We can in a certain rough way compute the increase in temperature that would arise from the collision of two great orbs. Thus, let us suppose that Nova Persei was moving onward through space with a velocity of ten miles a second—a moderate velocity, be it noted, for a star—when it collided with the body that wrought its destruction. The impact would be terrific, and the result of it would be not only the complete disintegration of both stars, but a sudden rise in temperature of about five hundred thousand degrees, an increase sufficient to vaporize the hardest adamant.

The second theory which has been suggested as explanatory not only of Nova Persei, but of all new stars, is a modification of the foregoing. This theory is that the new star in its flight through space suddenly plunged into a nebula, or into some portion of space denser than that through which it had already passed. This explanation is not only intelligible but reasonable. If the new star plunged into a region filled with matter even as rare as air, the friction would immediately set the star on fire. We see[235] the same phenomenon every night when a meteor hustles through our atmosphere. The meteoric rocks, with the chill of empty space in and around them, dash into our upper air. A few seconds are ample for the practical annihilation of most of them: in that brief space of time they have been subjected to a heat many times greater than that of a Bessemer furnace.

We can imagine Nova Persei as some monster meteor, a meteor larger than the sun, plunging into a gaseous mass somewhat like our air. In a few hours its temperature would be increased a million-fold. This increase would fill the surrounding space with fire, and there would be an immense and ever-increasing area at fervent heat.

To the mind of the writer this explanation has most to commend it. It is the one that is most in harmony with the information which has been gathered by hundreds of observers aided by the finest of modern scientific equipment. But there are other explanations. There will always be other explanations so long as the world lasts.

One of these explanations is of more interest than the rest, inasmuch as it makes a link of connection between the recent terrible volcanic eruption in the West Indies and the sudden appearance of a new star like Nova Persei. It is suggested that Nova Persei is, or rather was, a world somewhat like our own, only vastly larger—that is, there was an inner core of molten matter and an outer shell of solid material. One day, according to the explosion theory, this outer shell burst, and the interior fires[236] rushed hither and thither like a devouring flood all over the stellar globe. Vast chemical changes went on as the lambent flames turned everything solid into streams of lava. Great electrical disturbances took place all round the star. The whole phenomenon of Nova Persei, according to this theory, is just the destruction of St. Pierre on a sidereal scale.

Such a doom, of course, is possible in any star or planet whose interior is still molten. At any moment the imprisoned fires might break their barriers and change a cold, fruitful, life-bearing earth into a furnace; but it is far from probable that any such fate will ever be meted out to our planet or to any other, and, at any rate, destruction did not come to Nova Persei in this manner. No explosion could account for an access of heat and light any way comparable to that which was observed. Neither could any interior disruption be violent enough to hurl the star into fragments. The gravitational hold of the star would prevent this dismemberment. Yet during the ages the mind of man has been irresistibly drawn to this conception of the world's end, so much so that perhaps, after all, our instinct is right and our science wrong, and the vision of the Minorite Celano of the Dies iræ, dies illa Solvet sæculum in favilla,

is a vision of those things that will be in the later days.

We have already touched on one strange circumstance connected with the appearance of Nova[237] Persei. Dr. Anderson saw it for the first time at a few minutes to three o'clock on the morning of 22d February—that is, the news of the strange occurrence reached our planet then; but when did the event actually take place?

At Greenwich and at some of the other foremost observatories attempts have been made directly and indirectly to determine the distance of Nova Persei. And yet this distance defies measurement. The star is so far away that we have no instruments refined enough to deal with the problem. But we know that the sudden blazing up of Nova Persei was over and done with before our great-grandfathers were born. It happened more than two hundred years ago—perhaps two thousand years ago. All this time the news was swiftly traveling earthward, traveling on and on and on, two hundred thousand miles every second of the clock, past star and nebula and system, never halting, never faltering—yet it took hundreds of years to come to us; and beyond us lie countless worlds that will not see the new star for centuries to come. Hundreds of years hence in their sky will appear suddenly in the

constellation of Perseus a strange star; it will increase in brightness for a few days just as it did in ours; it will fade away intermittently just as it did in ours. There is no imagination here; only sober facts.

We may be allowed, in closing our narrative of this wonderful star, to make one excursion into the region of imagination. As the news of the star passes on through space, are there any beings beyond ourselves who will take record of its appearance? It[238] has taken centuries to come to us. Did any other creatures in some far-off world lift their eyes to the stars and wonder, as we do, what all this meant? Will some mortal, like ourselves, in some remoter world, in a day yet to come, see the sight, and have the intelligence to say, “Lo! a new star?” We have room enough here for the most extravagant fancy. Perhaps there is so much room that we shall lose ourselves if we venture to stray in such directions. TELESCOPES.—A. Fowler

The Refracting Telescope.—The function of a telescope is twofold. First, to magnify the heavenly bodies, or, what comes to the same thing, to make them look as if they were nearer to us, so that we can see them better. Second, to collect a much greater number of rays of light than the unassisted eye alone can grasp, so that objects too dim to be otherwise perceptible are brought within our range of vision.

There are two forms of telescope, distinguished as Refractors and Reflectors. The simplest form of refracting telescope is exemplified by the common opera-glass, and large refractors are not essentially different. Such instruments depend for their action upon the formation of an image by a lens. One can easily illustrate this by producing upon the wall of a room an inverted image of a candle or gas flame with a spectacle lens (one adapted for a long-sighted person), or with one of the larger lenses from an opera-glass. Having such an image, it may be magnified[239] by means of another lens, just as one may magnify a photograph with an ordinary reading glass. Technically, the lens which forms the primary image is called the object-glass of the telescope, and that which is used to magnify this image is called the eye-piece. The object-glass is usually a large lens, which is placed at one end of a tube, while the eye-piece is a much smaller lens, placed at the other end. Means are provided for adjusting the distance between the two lenses so as to admit of distinct vision.

Matters are, however, not quite so simple as has been stated. There is a very great difficulty introduced by the fact that a lens made out of a single piece of glass gives an image which is surrounded by fringes of color, so that some device has to be adopted in order to destroy, as far as possible, this enemy of good definition. In the early history of the telescope, this so-called chromatic aberration was considerably reduced by making small object-glasses of very great focal length.[22]

Lenses of 100-foot focus, however, are not easy to employ as object-glasses, and astronomy was, therefore, greatly benefited by Dollond’s invention of the achromatic lens in 1760. This is a compound lens, usually consisting of a double convex crown-glass lens and a concavo-convex, or double concave, lens of flint glass. The curvatures of the lenses, and the optical properties of the two kinds of glass composing[240] them, are such that the color due to one of them is practically neutralized by that due to the other acting in opposition. A section of such an object-glass, with the “cell” in which it rests, is shown in Fig. 20. Drawing of double lens Fig. 20.—The Achromatic Object-Glass

In this way the focal length of the lens, and, therefore, the length of the telescope tube, can be kept within reasonable dimensions, while the definition is improved. There is, however, usually a little outstanding color, due to the imperfect matching of the two lenses, and if one looks through a large refractor, even of a good quality, a purple fringe will be noticed round all very bright objects. This only affects a few of the brighter objects, while millions of others which are dimmer may be seen free from spurious color.

It may be remarked that the curved surfaces of the lenses forming telescopic object-glasses must not[241] be parts of spheres. If they are, the images will be rendered indistinct by spherical aberration, and the optician has to design his curves to get rid of this defect at the same time as chromatic aberration.

A new form of telescopic objective, consisting of three lenses, which has many important advantages, has been invented by Mr. Dennis Taylor, of the well-known firm of T. Cooke & Sons, York, England.

Such a lens as this illustrates the perfection which the optician’s art has now attained. Six surfaces of glass have to be so accurately figured that every ray of light falling upon the surface of the lens shall pass through the finest pin-hole at a distance of eighteen times the diameter of the lens.

The Reflector.—In a reflecting telescope, the object-glass of the refractor is replaced by a concave mirror. In order that such a mirror may reflect all the rays from a star to a single point, its concave surface must be part of a paraboloid of revolution, that is, a surface produced by the revolution of a parabola on its axis. If a spherical surface be employed, all the rays will not be reflected to a

single point and the images which it gives will be ill-defined. Yet it is astonishing to find that the difference between a parabolic and spherical surface, even in the case of a large mirror, is exceedingly small. Sir John Herschel states that in the case of a mirror four feet in diameter, and forming an image at a distance of forty feet, the parabolic only departs from the spherical form at the edges by less than a twenty-one thousandth part of an inch. Drawing of a telescope Fig. 21.—The Newtonian Reflector

An image being formed by a mirror, it is next to[242] be viewed with an eye-piece just as in the case of a refracting telescope. Here there is a little difficulty, for if the eye-piece be applied in the direct line of the mirror, the interposition of the observer's head will block out the light. Several ways of overcoming this have been devised, but the plan most generally followed is that which Newton adopted in the first reflecting telescope which was ever constructed. With his own hands Newton made a small reflector, 6¼ inches long and having an aperture of 1■ inches, with which he was able to study the phases of Venus and the phenomena of Jupiter's satellites. This precious little instrument is now one of the greatest treasures in the collection of the Royal Society of London. The general design of this telescope is shown in Fig. 21. The concave mirror is at the bottom of the telescope tube, and normally it would form an image of a star near the end of the tube. A plane mirror, however, of small size intercepts the rays and reflects them to the side, where they converge to a focus. This image is observed and magnified by an eye-piece, as in the refractor.[243] It is true that in this arrangement the plane mirror, or flat, renders the central part of the principal mirror ineffective, but the loss of light is very much less than would be the case if the eye-piece were placed in position to view the image centrally.

In the hands of Sir William Herschel the reflecting telescope was greatly developed. The great telescope with which he enriched astronomical science had a mirror four feet in diameter, and its tube was forty feet in length. With the view of utilizing the whole surface of the mirror and dispensing with a second reflecting surface, the 4-foot mirror was placed at a small angle to the bottom of the tube, so that its principal focal point was no longer at the centre, but at the side of the tube.

In practice, however, it is found that the Herschelian form of reflector does not give the best definition, and it is now very seldom seen.

Among other forms, the "Cassegrain" is perhaps the most important. During the last years this form has received a great deal of attention, more especially in regard to its special adaptability for photographic purposes.

In the Cassegrain telescope, the plane mirror of the Newtonian form is replaced by a small convex mirror which is part of a hyperboloid of revolution, its axis and focal point being coincident with those of the primary mirror. The rays are in this way reflected back to the mirror at the bottom of the tube, and in order that the image may be seen, it is necessary to cut out the middle part of the mirror to admit the eye-piece.

[244]

Although the small mirror must theoretically be hyperbolic, tolerable definition is obtained even if it be spherical or ellipsoidal, and its actual departure from these forms is so slight as to be beyond detection by measurement, so that the figuring of such mirrors can only be tested in the telescope. For photographic purposes this telescope has the very important advantage that a short telescope is equivalent to a very long one of the Newtonian form, or refracting telescope, so that the image of sun, moon, or planets formed at the focus is very large in comparison with the size of the telescope. A modification of this form of telescope, in which the small mirror is out of the path of the rays falling upon the larger one, and no longer obstructing the central part, has been revived by Dr. Common, and has become generally known as the "Skew Cassegrain."

In reflecting telescopes the mirrors were formerly made of speculum metal (an alloy of copper and tin), and the word speculum is even now commonly employed to signify a telescopic mirror, although it is usual to make the mirror of glass, with the concave surface silvered and highly polished.

One is frequently asked for an opinion as to which is the better form of telescope, the reflector or refractor, and it is a question that one finds some little difficulty in answering. On one point, however, all are agreed, namely, that the reflector has the advantage in regard to its achromatism; it is indeed perfectly achromatic, while the so-called "achromatic" refractor is at best only a compromise. For the rest, one can not do better than quote the evidence of Dr.[245] Isaac Roberts before the International Astrophotographic Congress: "The reflector requires the exercise of great care and patience, and a thorough personal interest on the part of the observer using it. In the hands of such a person it yields excellent results, but in other hands it might be a bad instrument. The reflector gives results at least equal, if not superior, to those obtained with the refractor, if the observer be careful of the centring, and of the polish of the mirror, and keeps the instrument in the highest state of efficiency; but when intrusted to an ordinary

assistant the conditions necessary for its best performance can not be so well fulfilled as the same could be in the case of the refractor." One great practical advantage of the reflector is that there are fewer optical surfaces, so that a large reflector may be obtained for the price of a much smaller refractor. Drawing of a telescope Fig. 22.—The Cassegrain Reflector

Eye-Pieces.—So far we have regarded the eye-piece of a telescope as a simple lens, but it is evident that the spherical and chromatic aberration of such a lens will interfere with its performance. For occasional[246] use, however, even a simple lens is very serviceable if the object observed is brought to the centre of the field of view.

Compound eye-pieces are of various forms, each having certain advantages, the desiderata being freedom from color and "flatness of field"—that is, stars in different parts of the field are to be equally well in focus. Those most commonly employed are the Ramsden and Huyghenian eye-pieces. The former consists of two plano-convex lenses of equal focal lengths, having their curved faces toward each other, and being placed at a distance apart equal to two-thirds of the focal length of either lens. Such an eye-piece can be used as a magnifying-glass, and it is therefore placed outside the focal image formed by the telescope with which it is used; on this account it is called a positive eye-piece. This kind of eye-piece is not quite achromatic, but its flat field of view gives it a special value for many purposes.

In the Huyghenian eye-piece there are again two lenses, made of the same kind of glass. That which comes nearest to the eye has a focal length of only one-third that of the field lens, and the distance between the two lenses is half the sum of the focal lengths. This form of eye-piece can not be used as a magnifying-glass in the ordinary sense, and as the field lens must be placed on the object-glass or mirror side of the focus, it is called a negative eye-piece. The Huyghenian eye-piece is more achromatic than the Ramsden, and is more widely used when it is only required to view the heavenly bodies. In instruments employed for purposes of measurement, a positive[247] eye-piece is essential in order that the spider threads may be placed at the focus of the telescope. The images formed by an astronomical telescope are upside down, and neither of the eye-pieces described reinverts them.

A special form of eye-piece is therefore used when a telescope is employed for terrestrial sight-seeing. The desired result is obtained by the introduction of additional lenses, but there is a corresponding reduction of brightness.

For viewing the sun some device is necessary to reduce the quantity of light entering the eye. To look at the sun directly, even with a small instrument, is very dangerous. The arrangement usually adopted is a solar diagonal, in which the light is reflected from a piece of plane glass before entering the eye-piece; the piece of glass is wedge-shaped, so that the reflection from one surface only is effective; if the glass had parallel sides, the solar image would be double.

Magnifying Power.—The magnifying power of a telescope depends upon the focal length of the object-glass, or speculum, and that of the eye-piece. Optically, it is equal to the former divided by the latter, so that the greater the focal length of an object-glass, or the smaller the focal length of the eye-piece, the greater will be the magnifying power. In a given telescope, the object-glass, or speculum, is a constant factor and the magnifying power can only be varied by changing the eye-piece. The focal length of the Lick telescope, for example, is about 600 inches; with an eye-piece which is equivalent to a lens of one-inch focus, the magnifying power[248] would be 600; with a lens of half an inch focus, it would be 1,200, and so on.

The magnifying power which can be effectively employed, however, depends upon a great variety of circumstances. First, the clearness and steadiness of the air; then there is the quality of the object-glass, or speculum, to be considered; and also the brightness of the object to be observed, for when the object is very dim, its light will be spread out into invisibility if too high a power be used.

In practice, good refractors perform well with powers ranging up to 80 or 100 for each inch in the diameter of the object-glass. Thus, on sufficiently bright objects, a six-inch telescope will work well with a power of about 500, while a 30-inch may be effectively employed with powers between 2,000 and 3,000.

Illuminating Power.—It has already been pointed out that magnification is not the only function of a telescope. As a matter of fact, the most powerful telescopes in the world fail to produce the slightest increase in the apparent size of a star, for even if these objects be brought to apparently a 3,000th part of their real distances, they are still too far away to have any visible size. But although a star can not be magnified, it can be rendered more visible by the telescope, for the reason that the object-glass collects a greater number of rays than the naked eye. The pupil of the eye may be taken to have a diameter of one-fifth of an inch; a lens one-inch in diameter will have twenty-five times the area of the pupil, and will therefore collect twenty-five times[249] the amount of light from a star; a two-inch lens will grasp one hundred times, and a 36-inch 32,400 times as much light as the pupil alone.

Practically all these rays collected by the object-glass, or speculum, of a telescope can not be brought into the eye; some are lost through the imperfect transparency of the glass, or the imperfect reflecting power of the speculum. Still, allowing a considerable percentage for loss, there is an enormous concentration of light when a large telescope is employed.

The Altazimuth Mounting.—Having got a telescope, we have next to see how it can be best supported, for unless it be a very small instrument indeed, it will be impossible to hold it in the hand like a spy-glass. However a telescope be mounted, provision must be made for turning it to any part of the sky whatsoever. Very frequently one of the axes on which the instrument turns is vertical, while the other is horizontal. Such a stand for a telescope is called an altazimuth mounting, for the reason that it permits the instrument to be moved in altitude and in azimuth.

As a rule, one finds only small telescopes mounted in this manner. The objection to it is that, as one continues to observe a heavenly body, two independent movements must be given to the telescope in order to follow the body in its diurnal movement across the heavens. If we commence observing a star newly risen, for example, the telescope must trace a star-like path in order to follow it as it ascends into the heavens.

The Equatorial Telescope.—A much more convenient[250] method of setting up a telescope is to mount it as an equatorial. The essential feature of this instrument is that one of the axes of movement, instead of being vertical, is placed parallel to the axis of the earth. This is called the polar axis, and, when the telescope is turned around such an axis, it traces out curves in the sky which are identical with those described by the stars in their diurnal motions. If, then, the telescope be directed to a star or other heavenly body, it can be made to follow the object and keep it in view by a single movement. The axis at right angles to the polar axis is called the declination axis, and is necessary in order that the telescope may be moved toward and from the poles so that all the heavenly bodies above the horizon may be included in its sweep.

One very important advantage of the equatorial is that, as only one motion is required to keep a star in view, so long as it is above the horizon, the necessary movement may be furnished by clockwork. A good equatorial is accordingly provided with a driving-clock, which is regulated so that it would drive the telescope through a whole revolution once a day. Unlike an ordinary clock, the driving-clock of a telescope is regulated by a governor, in order that the instrument may have a continuous and not a jerky movement.

The telescope is also provided with clamps and fine adjustments, one each in R. A. and declination, in order that it may be under the control of the observer. It is evident that the telescope must be capable of moving independently of the driving-gear, so[251] that it may first be placed in the desired direction; when this is accomplished, the R. A. clamp is used to put the telescope in gear with the clock. The declination clamp is then made to fix the telescope firmly to the declination axis. Fine adjustments in both directions are necessary, because it is impossible to sight a large instrument with such precision as to bring an object exactly to the centre of the field of view.

Some of the driving-clocks fitted to equatorials are very elaborate. As clocks regulated by governors are not such reliable timekeepers as those regulated by pendulums, arrangements are made by which the accuracy of a pendulum can be electrically communicated to a governor clock. One of the best forms of electrically controlled clocks is that devised by Sir Howard Grubb.

Another important feature of an equatorial is that it can be provided with circles which enable the telescope to be pointed to any desired object of known right ascension and declination. One of these is the declination circle, attached to the declination axis and read by a vernier fixed to the sleeve in which the axis turns; this is adjusted so as to read 0° when the telescope points to any part of the celestial equator, and 90° when it is directed to the pole. The other circle is attached to the polar axis, and determines the position of the telescope with regard to the meridian; this is called the hour circle, and is divided into twenty-four hours. When the telescope is on the meridian, the hour circle reads zero, so that its reading in any other position gives the hour angle[252] of the telescope. Having given the right ascension and declination of a heavenly body which it is desired to observe, the telescope is turned until the declination circle reads the proper angle, and the hour circle indicates the hour angle which is calculated for the particular moment of pointing the telescope. [The hour angle is the difference between the right ascension of the object and the sidereal time of observation.] In this way it is easy to find objects of known position which are invisible to the naked eye, and one can even pick up the planets and brighter stars in full sunshine. Conversely, one can determine from the circles the right ascension and declination of any object under observation, but for various reasons only approximate results can be obtained in this way. The chief use of the circles on an equatorial is therefore to provide a means of pointing the telescope.

Telescopes of four inches aperture and upward are usually provided with a smaller companion called a finder. This has a larger field of view than the main telescope, so that objects which are of sufficient brightness can readily be picked up and brought to the centre of the finder, the adjustments being such that the object is then also at the centre of the field of the large telescope.

There are, of course, many practical details connected with the working of an equatorial with which space does not permit us to deal. It may be remarked, however, that the adjustment of the polar axis is very simply performed by first inclining it at an angle approximately equal to the latitude of the[253] place where it is set up, and setting it as nearly as possible in the meridian by means of a compass or by observations of the sun at noon. The final adjustment is then made by a series of observations of stars of known position.

Some of the World's Great Telescopes.—Thanks to the wide public interest taken in astronomical matters, a large number of powerful telescopes have been set up in various parts of the world. To the British Islands belongs the honor of possessing the largest telescope in the world. This is the giant reflector erected by Lord Rosse, in 1842, at Parsonstown, the mirror being six feet in diameter, and the focal length sixty feet. Many very valuable observations were made with this instrument in its early days, but of late years it seems to have fallen into disuse. One reason may be that the mounting is not of the most convenient form, and makes the telescope unsuitable for photographic work.

Coming next in point of size to the Rosse telescope is the reflector erected at Ealing by Dr. A. A. Common. The glass mirror of this telescope is five feet in diameter, five inches thick, and weighs more than half a ton. Dr. Common aimed specially at constructing the largest possible telescope which could be equatorially mounted and provided with a driving-clock, and he was only limited to an aperture of five feet by the impossibility of obtaining a glass disk of larger size. He has attained such great skill in this work that he was able to produce a perfect mirror five feet in diameter in three months' time, although[254] no less than 410,000 strokes of the polishing machine were required.

The telescope is of the Newtonian form, and the mounting is quite unique. The polar axis consists of an iron cylinder, made up of boiler plate, seven feet eight inches in diameter, and about fifteen feet long. From the top of the cylinder, near its outer edge, two horns, each six feet long, project outward, and the tube of the telescope swings on trunnions attached to the ends of the horns. The main part of the telescope tube is square, built up of steel angle iron, and carries the mirror at its lower end; the upper part of the tube, which carries the "flat" and eye-piece, is round, and of tinned steel strengthened by a skeleton framework.

It is evident that such an enormous instrument as this can not be made to travel by clockwork with the necessary uniformity without some very efficient arrangement for reducing friction. Dr. Common's plan—and it is here that his instrument is unlike others—is to make the hollow polar axis watertight, and to fix it in a tank of water. At the bottom of the polar axis is a ball and socket joint to keep it in position, and at the top is another bearing, which can be adjusted so that the polar axis lies truly in the meridian. It was found necessary to introduce nine tons of iron into the bottom of the hollow polar axis in order to sink it to the proper angle, and to put sufficient weight on the bearings to give stability to the instrument. In this way the great mass is brought into the region of manageability, and the driving-clock, which is driven by a weight of one and a half[255] tons, is able to do its work efficiently. Such, in general outline, is this wonderful telescope, which, although not so large as Lord Rosse's famous instrument, is undoubtedly its superior in light-grasping power and general utility, and more especially in its adaptability for photographing the heavens.

Among other large reflecting telescopes now in use are the 4-foot reflectors at Melbourne and Paris, and the 3-foot reflectors at South Kensington and the Lick Observatory, California.

The largest refracting telescope yet constructed is one of forty inches aperture for the Yerkes Observatory of the University of Chicago. It is interesting to note here that Professor Keeler, in his report as an expert upon the performance of the object-glass, considers that there is "evidence for the first time that we are approaching the limit of size in the construction of great objectives." Unlike a mirror, a lens can be supported only upon its circumference, and it is the bending by its own weight that proves detrimental to its defining power. If the lens be made thicker with a view of overcoming this defect, the absorption of light by the glass increases, so that there is in the end no special gain by increasing the size.

The length of the Yerkes telescope is 62 feet, and is provided with all accessories pertaining to astrophysical research. The world-renowed Lick Telescope is of thirty-six inches aperture. The story of the foundation of this monster instrument is not much less wonderful than the telescope itself.[256] Brought up in poor circumstances, with few opportunities for intellectual development, James Lick, nevertheless, amassed a fortune in business, and having few relations, he was anxious to dispose of his wealth in such a way as to bring him that fame which he had failed to achieve in other directions. Although it is very probable that he had

never looked through a telescope in his life, the idea of a large telescope had taken a very firm hold upon his mind, and, thanks to the influence of his advisers, it was definitely announced in 1873 that Mr. Lick's bid for immortality was to take this form. Several sites were examined by experts, and finally Mount Hamilton, California, 4,200 feet above sea-level, was selected. An excellent road, twenty-six miles in length, made at the cost of the county authorities, connects the observatory with the nearest town, San José, thirteen miles distant.

Owing to various delays, operations were not commenced until 1880, and five years were consumed in clearing away 72,000 tons of rocks and in erecting the buildings.

Mr. Lick had stipulated for the erection of "a telescope superior to and more powerful than any telescope yet made," and Messrs. Alvan Clark & Co. contracted to supply a lens of thirty-six inches aperture for the sum of $50,000. It turned out, however, that it was much easier to make such a contract than to fulfil it. To produce large disks of optically perfect glass, even in the rough, requires the greatest possible skill and patience, and this part of the work was undertaken by Feil & Co. of Paris. The flint[257] glass disk was safely delivered in America in 1882, but the crown disk was cracked in packing. The elder Feil having retired from business, the duty of providing a new block of crown glass devolved upon his sons, who, after two years spent in vain attempts, ended in bankruptcy, and it was only through the elder Feil again resuming business that the much-required disk was finally completed in 1885. After the lapse of another year, the rough disks were fashioned, in the workshops of the Clarks, into the most marvelous of telescopic lenses.

The mounting of the object-glass is worthy of the occasion. The tube is no less than thirty-seven feet long, and four feet in diameter in the middle part. An iron pier, thirty-eight feet high, beneath which lie the remains of Mr. Lick, supports the equatorial head, and a winding staircase enables the observer to reach the setting circles. Inside the hollow pier is the powerful driving-clock which turns the telescope to follow the heavenly bodies in their apparent movements. Finders of six, four, and three inches diameter, rods for the manipulation of the instrument, and all necessary accessories, complete what must long remain one of the most perfect instruments at the service of astronomical science. The $200,000 expended upon it have already been amply justified by the work accomplished, while Mr. Lick's dream of immortality has become a reality.

The following list indicates some of the large refractors now doing active service:

[258] Aperture Observatory 36 inch [Lick] California. 30 ” Pulkowa, Russia. 30 ” [Bischoffeim] Nice. 28 ” Greenwich. 27 ” Vienna. 26 ” Washington. 25 ” [Newall] Cambridge. 24 ” [Lowell] Mexico. 23 ” Princeton, New Jersey.

It is right to add, however, that opinion is still greatly divided as to whether these telescopes of large aperture really repay the expense and labor involved in their erection and use. On the very rare occasion when the "seeing" is practically perfect—which occurs perhaps only a few hours in a year—it is probable that the superiority of a large telescope is very marked, but under average conditions there seems to be little advantage over instruments of moderate size for many classes of observations.

Certain it is that a great deal of valuable work is done with comparatively small telescopes, ranging from six to fifteen inches aperture, and this in all departments of astronomical research. Hence, some of the most active observatories do not figure in the above list; among them may be mentioned the observatories of Harvard College, Potsdam, Paris, Heidelberg, Cape of Good Hope, Edinburgh, South Kensington, Stonyhurst College, and the observatory of Dr. Isaac Roberts at Crowborough, England.

Housing of Equatorials.—The building which accommodates an equatorial telescope must evidently be designed to admit of giving a clear opening to any part of the sky. Usually this is accomplished[259] by making the roof, or dome, with a circular base, provided with wheels, which run on rails. It is then only necessary to open a narrow portion of the dome, extending from top to base, and to turn the dome until this aperture is in the required direction. One of the most elaborate domes now in existence is that built by M. Eiffel for the great refractor of the Nice Observatory. The lower part of the building is in the form of a square, having a side of about eighty-seven feet and a height of about thirty feet. The dome itself is seventy-four feet in diameter, and the moving parts alone weigh ninety-five tons.

There are two shutters, each a little wider than half the possible opening; these run on short rails, and are moved simultaneously by means of an endless rope. The whole of the dome is built up of steel angle iron, covered with very thin sheet steel. In order to facilitate the manipulation of the dome, its great weight is buoyed up by means of a float attached to its base and immersed in a circular tank of water of a little greater size than the base of the dome. If any mishap occurs with this gigantic tank, the dome rests on wheels which run on a circular rail, so that the work need not be interrupted. The whole arrangement is very easily turned with

the aid of a winch by one man when the dome is floating, but when resting on the wheels several men are required at the winch.

This brief description will serve to illustrate some of the problems which confront the possessor of a very large telescope. For smaller instruments, the observatories follow pretty nearly the same plan, except[260] that it is unnecessary to provide an arrangement for floating the dome.

The observatory which shelters a reflecting telescope need not differ very greatly from one which contains a refractor. If the instrument be a Newtonian, it is generally convenient to sink the polar axis below the level of the floor in order that the observer may not be at too great a height from the ground, and in that case, the dome, or its equivalent, is all that is necessary. For his five-foot reflector, Dr. Common designed an observatory which is not of the ordinary form, but gives the necessary opening partly by means of large shutters and partly by a revolution of the whole house. It is not every one who is able to lay out $40,000 on such a dome as that erected at Nice by M. Bischoffeim.

The varying position of the eye end of a telescope, when it is turned to different parts of the sky, makes it necessary to provide comfortable and safe seating accommodation for the observer, more especially when the telescope is a very large one. In the case of the Yerkes telescope, the eye-piece is thirty feet higher when observing near the horizon than when observing near the zenith, and the observer must necessarily follow the telescope. The most convenient arrangement in such a case is to raise or lower the floor of the observatory as occasion demands. The floor of the Yerkes Observatory is seventy-five feet in diameter, and by means of electric motors it can be given a vertical motion of twenty-two feet. A similar arrangement was provided for the Lick telescope from the designs of Sir Howard[261] Grubb. With smaller instruments, observing ladders and adjustable chairs of various forms are employed.

The Equatorial Coudé.—A form of equatorial telescope which has possibly a great future before it is one introduced at Paris under the name of the equatorial coudé, or elbowed telescope. Its practical advantage is that the observer remains in a constant and comfortable position, so that revolving domes and elevating floors, or other arrangements serving similar purposes, are no longer necessary. The telescope tube is of two parts of nearly equal length, and what is ordinarily the lower half of the tube forms part of the polar axis, while the other half is attached to it at right angles. At the point of intersection of the two halves of the tube is a plane mirror, and there is another mirror in front of the object-glass. If the latter mirror were removed, such a telescope would only enable the observer to see objects lying along the celestial equator, but by its means objects in all parts of the heavens can be brought within range to an observer gazing down the hollow polar axis. The largest instrument is that at the Paris Observatory, which has an object-glass 23½ inches in diameter for visual observations, and another of the same size for photographic purposes.

Fixed Telescopes.—There is still another method of using a telescope. The telescope itself may be fixed, and the light of the heavenly bodies may be reflected into it by means of a mirror which is made to revolve so as to keep pace with their movements. Foucault devised an instrument called the siderostat[262] for this purpose, and although it is not largely employed for telescopic observations, it is very widely utilized for spectroscopic work, where the spectroscope is of a kind not readily attached to a telescope.

Another instrument used for the same purpose has recently been brought forward under the name of the cœlostat. This is simply a mirror which is made to turn on a polar axis in its own plane, and since a reflected ray of light moves through twice the angle that the reflecting surface turns through, the mirror is made to revolve at the rate of one revolution in two days. As the name indicates, the whole heavens appear stationary in such an instrument, whereas in a siderostat only one star at a time appears at rest, while its neighbors slowly revolve round it.

Photographic Telescopes.—The application of photography to the study of the heavenly bodies marks one of the greatest advances of the present century. The instruments which are employed for this purpose range from the ordinary tourist camera to the largest telescope. Unlike a person sitting for a portrait, the heavenly bodies can not be made to stand still for the purpose, and as instantaneous photographs can only be obtained in the case of the sun and moon, it is usually necessary to make the camera follow the stars very exactly during the time of exposure in order that the images may fall on precisely the same parts of the photographic plate.

Some guiding arrangement is, therefore, essential, and generally the photographic camera or telescope is attached to an ordinary equatorial which is driven[263] by clockwork, or very carefully by hand if the camera be a small one. In the guiding telescope are two spider-threads at right angles to each other, and it is by constantly keeping the image of a star at the intersection of these “wires” that the operator ensures the images remaining in a constant position upon the sensitive plate.

An ordinary portrait camera, in the hands of a skilled observer, yields very beautiful pictures, but they are naturally on a small scale. The field of view of such an instrument is so large that a whole constellation may be photographed with a single exposure.

Portrait lenses of six inches aperture in the hands of Dr. Max Wolf and Professor Barnard have given magnificent delineations of the Milky Way, and of the extremely faint nebulosities which are to be found in many parts of the heavens.

For many purposes, however, telescopes of greater power are required, and here it may be remarked that the distance between the images of any two adjacent stars will vary in direct proportion to the focal length of the telescope. In the same way the size of the image of a planet, the moon, or a comet, increases as the focal length of the objective is increased.

Refracting telescopes which are employed for photography require object-glasses which are specially “corrected” for the photographic rays. White light is compounded of light of all colors, but it is the blue and violet constituents which are effective in producing photographic action on an ordinary[264] sensitive plate. Now, an object-glass which is intended for visual purposes is made to focus at the same point as many as possible of the rays which are most effective to the human eye, that is the green, yellow, and red, and usually there is a blue or purple halo round the images of the brighter objects, which is, however, too feeble as a rule to interfere with visual observations. This blue halo will evidently result in defective definition if the lens be employed for photography. By putting the plate at the point where the blue rays are most nearly focused, a better image is obtained; but for really good work a photographic object-glass must be so designed that all the blue and violet rays are brought to one and the same focus. Such a lens will consequently be a very poor one for visual observations.

The new “photo telescopic” object-glass now manufactured by Messrs. Cooke appears to be full of promise. In this lens all the colors of the spectrum are brought to almost exactly the same focal point, so that it serves equally well for photographic or visual purposes.

This difficulty in regard to achromatism does not exist in the case of the reflecting telescope, since rays of light of every color are reflected at precisely the same angles. For this reason reflectors, when properly managed, give the best photographic results. Dr. Isaac Roberts and Dr. Common are especially identified with the application of the reflecting telescope for celestial photography. The instrument employed by the former consists of a 20-inch reflector and a 7-inch guiding telescope of[265] the refracting form. The two telescopes are mounted on the extreme ends of the declination axis of an equatorial.

Dr. Common does not employ a guiding telescope at all. The photographic plate which he places at the focus of the reflector is smaller than the field of view, so that by means of an eye-piece fitted with a cross wire at the side of the dark slide, he is able to watch a star near the edge of the field. Both eye-piece and dark slide are attached to a frame which can be controlled by two screws at right angles to each other. If the guiding star leaves the cross wire through errors in driving, or other causes, the eye-piece and dark slide are bodily moved after it by means of the adjusting screws. This method not only has the advantage of saving the cost of a guiding telescope, but reduces the effects of vibration consequent upon the correction of errors by moving the whole telescope.

For photographing the sun a special instrument called a photoheliograph is usually employed. This differs only from an ordinary photographic telescope in being provided with a secondary magnifier, by which means the focal image formed by the object-glass is amplified before falling upon the photographic plate. On a bright, clear day pictures of the sun eight inches in diameter can be taken with an exposure of about 1/500th of a second, and such a photograph will frequently record more facts as to the state of the solar surface than a whole day’s observation. Lenses or mirrors of very long focus are also occasionally employed in solar photography,[266] and in this way a large image is obtained without the use of a secondary magnifier.

Photographs of the moon and planets may be taken either with or without a secondary magnifier, but in either case the exposures are longer than for the sun.

Finally, it may be added that the sensitive plates and processes used in astronomical photography do not differ from those employed by ordinary photographers. FOOTNOTES:

[22] The focal length of a lens is the distance from its centre at which an image of a very distant object, such as the sun, is formed. METEORS.—Sir Robert S. Ball

Our present knowledge as to the natural history of the shooting stars has been mainly acquired during the last hundred years. The first important step in the comprehension of these bodies was to recognize that the brilliant flash of light was caused by some object

which came from without and plunged into our air. This was known at the end of the Eighteenth Century, largely by the labors of the philosopher Chladni in 1794. Photo of a moon region A Portion of the Moon's Disk Where Four Mountain Ranges Meet

Could an ordinary shooting star tell us its actual history, the narrative would run somewhat as follows:

"I was a small bit of material, chiefly, if not entirely, composed of substances which are formed from the same chemical elements as those you find on the earth. Not improbably I may have had some iron in my constitution, and also sodium and carbon, to mention only a few of the most familiar elements. I only weighed an ounce or two, perhaps more, perhaps less—but you could probably have held me in[267] your closed hand, or put me into your waistcoat pocket. You would have described me as a sort of small stone, yet I think you would have added that I was very unlike the ordinary stones with which you were familiar. I have led a life of the most extraordinary activity; I have never known what it was to stay still; I have been ever on the move. Through the solitudes of space I have dashed along with a speed which you can hardly conceive. Compare my ordinary motion with your most rapid railway trains; my journey will be done ere the best locomotive ever built could have drawn the train out of the station. Pit me against your rifle bullets, against the shots from your one-hundred-ton guns; before the missile from the mightiest piece of ordnance ever fired shall have gone ten yards I have gone 1,000 yards. I do not assert that my speed has been invariable—sometimes it has been faster, sometimes it has been slower; but I have generally done my million miles a day at the very least. Such has been my career, not for hours or days, but for years and for centuries, probably for untold ages. And the grand catastrophe in which I vanished has been befitting to a life of such transcendent excitement and activity; I have perished instantly, and in a streak of splendor. In the course of my immemorial wanderings I have occasionally passed near some of the great bodies in the heavens; I have also not improbably in former years hurried by that globe on which you live. On those occasions you never saw me, you never could have seen me, not even if you had used the mightiest telescope that has ever been directed to the heavens. But too close[268] an approach to your globe was at last the occasion of my fall. You must remember that you live on the earth buried beneath a great ocean of air. Viewed from outside space, your earth is seen to be a great ball, everywhere swathed with this thick coating of air. Beyond the appreciable limits of the air stretches the open space, and there it is that my prodigious journeys have been performed. Out there we have a freedom to move of which you who live in a dense atmosphere have no conception. Whenever you attempt to produce rapid motion on the earth, the resistance of your air largely detracts from the velocity that would be otherwise attainable. Your quick trains are impeded by air, your artillery ranges are shortened by it. Movements like mine would be impossible in air like yours.

"And this air it is which has ultimately compassed my destruction. So long as I merely passed near your earth, but kept clear of that deadly net which you have spread, in the shape of your atmosphere, to entrap the shooting stars, all went well with me. I felt the ponderous mass of the earth, and I swerved a little in compliance with its attraction; but my supreme velocity preserved me, and I hurried past unscathed. I had many narrow escapes from capture during the lapse of those countless ages in which I have been wandering through space. But at last I approached once too often to the earth. On this fatal occasion my course led me to graze your globe so closely that I could not get by without traversing the higher parts of the atmosphere. Accordingly, a frightful catastrophe immediately occurred. Not[269] to you; it did you no harm; indeed, quite the contrary. My dissolution gave you a pleasing and instructive exhibition. It was then, for the first time, that you were permitted to see me, and you called me a shooting star or a meteor.

"When from the freedom of open space I darted into the atmosphere, I rubbed past every particle of air which I touched in my impetuous flight, and in doing so I experienced the usual consequence of friction—I was warmed by the operation.

"You can readily comprehend the immense quantity of heat that will have been produced ere friction could deprive me of a speed of twenty miles a second. That heat not merely warmed me, but I rapidly became red-hot, white-hot, then I melted, even though composed of materials of a most refractory kind. Still friction had much more to do, and it actually drove me off into vapor, and I vanished. You, standing on your earth many miles below, never saw me—never could have seen me—until this supreme moment, when, glowing with an instantaneous fervor, I for a brief second became visible.

"Nature knows no annihilation, and though I had been driven off into vapor and the trial by fire had scattered and dispersed me, yet in the lofty heights of the atmosphere those vapors cooled and condensed. They did not, they never could again reunite and reproduce my pristine structure. Here and there in wide diffusion I repassed from the vaporous to the solid form, and in this state I wore the appearance of a streak of minute granules distributed all along the highway I had followed. These granules[270] gradually subsided through the air to the earth. On Alpine snows, far removed from the haunts of men and from contamination of chimneys, minute particles have been gathered, many of which have unquestionably been derived from the scattered remains of shooting

stars. Into the sea similar particles are forever falling, and they have been subsequently dredged up from profound depths, having subsided through an ocean of water after sinking through an ocean of air."

Those splendid shooting stars which are often called fire-balls move in every direction. They come from the east, and from the west, from the north, and from the south. There is no hour of the night at which they have not occasionally been seen. Even in daylight it has happened not once or twice, but on several occasions, that a brilliant meteor has forced itself upon our astonished notice. They generally first make their appearance at a height which is between fifty and one hundred miles above the ground. They hurry down their inclined path, but generally become extinguished while still at least twenty miles aloft. In their more ambitious flights meteors have been known to span a kingdom. Nor are even greater strides unrecorded. The length of a continent may be compared with the track of that terrific meteor of 5th September, 1868, which broke into visibility at an appalling height above the Black Sea, and had not expended its stupendous energy until it passed over the smiling vineyards of France.

Great fire-balls are much more numerous than any[271] one would suppose who had not paid attention to the subject. Nor need this be a matter for surprise if it be remembered that when a fire-ball does arrive it is only by a favorable combination of circumstances that any particular individual is privileged to witness the exhibition. As a random example of the yearly crop of fire-balls, I take from the middle of 1877 to the middle of 1878. A list of the fire-balls noticed during this period will be found in that store-house of valuable information, the Reports of the British Association. In the year referred to I see that eighty-six great fire-balls have been recorded. They have appeared in various localities, both in the old hemisphere and in the new. The most arduous observer may think himself fortunate if he has even seen one of them.

As to the brilliant light from some of these great fire-balls, there are numerous statements. We are not infrequently told that even the beams of the full moon are ineffectual in comparison with the blaze of the meteor; and we find a high authority asserting that one of these bodies displayed a flash as "blinding as the sun." On the 29th July, 1878, a fire-ball was seen which created so splendid an illumination that "the smallest objects were visible at Manchester."

Fortunate, indeed, would the astronomer have been who, guided by some miraculous prescience, had gone to the ancient city of York on the evening of the 23d of February, 1879, and on the tower of the glorious minster spent the night in observation of the heavens. It would have been his privilege to[272] witness a majestic meteor under circumstances of almost unique magnificence.

It was at seven minutes before three that such few stragglers as the streets of York still contained saw a pear-shaped ball of fire traveling across the sky. It drenched the ancient city with a flood of light. The superb front of the minster never before glowed with a more romantic illumination. The unwonted brilliancy streamed through every aperture in every window in the city; every wakeful eye was instantly on the alert; every light sleeper started up suddenly to know what was the matter. Even those whom the blaze of midnight light had failed to awaken were only permitted to protract their slumbers for another minute and a half—only until an awful crash, like a mighty peal of thunder, burst over the town, shaking the doors, the windows, and even the houses themselves. The whole city was thus alarmed. Every one started at the noise. But that noise was not a clap of thunder. Nor was it produced by an earthquake. It was merely the explosion of the fire-ball which flung itself against the atmosphere after its immeasurable voyage through space.

Perhaps the most remarkable instance of the explosion of a meteor is recorded in the case of the great fire-ball so widely observed in America on the 21st of December, 1876. The movements of this superb object have been carefully studied by Professor H. A. Newton and Professor D. Kirkwood. For the prodigious span of a thousand miles this meteor tore over the American continent with a speed[273] of some ten or fifteen miles a second. It first appeared over Kansas at a height of seventy-five miles. Thence it glided over the Mississippi, over the Missouri; it passed to the south of Lake Michigan; it made a short voyage over Lake Erie, and it can not have been very far from the Falls of Niagara, when by becoming invisible all further traces of its movements were lost. While passing a point midway between Chicago and St. Louis a frightful explosion shivered the meteor into a cluster of brilliant balls of fire, which seemed to chase each other across the sky. This cluster must have been about forty miles long and five miles wide. The detonation by which the explosion was accompanied was a specially notable incident of this meteor. It was not only heard with terrific intensity in the neighborhood, but the volume of sound was borne to great distances.

The glory of a meteor is often so evanescent that we just get a glimpse and it is gone. The sky resumes its ordinary aspect; the familiar stars are there, and even the very situation of the brilliant streak has become unrecognizable. But this is not always so; it sometimes happens that the brief career of the meteor leaves a notable trace behind it, so that for seconds and for minutes the sky is diversified by an unwonted spectacle. The path of the meteor leaves a stain of pearly light on the sky to mark the highway

pursued by our celestial visitor.

In its fearful career the meteor is often rent to fragments, reduced to dust, dissolved into vapor. The glowing atoms of the wreck lie strewn along the path, just as the ghastly remnants of Napoleon's[274] mighty army limned out the awful retreat from Moscow.

A pencil-shaped cloud of meteoric débris, perhaps eighty or a hundred miles in length, and four or five miles in diameter, thus hangs poised in air. It is at night. The sun has sunk so far below the horizon that there is no trace of the feeblest twilight glow. An ordinary cloud would, of course, be invisible except as concealing the stars; no beams of light fall upon it; there is nothing to render it luminous. So, too, the meteoric streak will often pass instantly into invisibility, but, as I have said, this is not always the case. There is a well-authenticated instance in which the trail of a superb meteor remained visible for nearly an hour. I have endeavored up to the present to explain the various phenomena presented to us in the fall of a meteor, but here, for the first time, we have to note a circumstance for which it is not easy to account. We can explain why it is that the long meteoric cloud should be there, but we can not so easily explain why we should be able to see it. Whence comes this beautiful pearly luminosity? It seems that the meteoric dust must glow with some intrinsic luminosity.

We have spoken of dazzling fire-balls which generate for a brief moment a light which eye-witnesses, with possibly a pardonable exaggeration, have ventured to compare with the beams of the sun himself. Other meteors are described as being as bright as the full moon. Descending still lower in the scale of splendor, we read of fire-balls as bright as Venus or Jupiter, as bright as Sirius, or as a star of the first[275] magnitude. With each step downward in brilliancy we find the meteors to increase in numerical abundance. Shooting stars as bright as the stars of the second or third magnitude are comparatively frequent; they are still more numerous of the fourth and fifth magnitudes. Every night brings its tale of shooting stars whose brightness is just sufficient to impress the unaided eye. Nor do the shooting stars which even the most attentive eye can detect represent a fraction of their entire number. As there are telescopic stars which the unaided eye can not see, so it might fairly be conjectured that, as we can trace meteors of successive stages of brightness down to the limit of unaided eye visibility, so there may be meteors still and still smaller which would be detected could we only direct a telescope toward them.

If we reflect that for every one that is seen there must be thousands which dart in unseen, we obtain an imposing idea of the myriads of shooting stars that daily rain in upon our globe.

The world is thus pelted on all sides day and night, year after year, century after century, by troops and battalions of shooting stars of every size, from objects not much larger than grains of sand up to mighty masses which can only be expressed in tons. In the lapse of ages our globe must thus be gradually growing by the everlasting deposit of meteoric débris. Looking back through the vistas of time past, it becomes impossible to estimate how much of the solid earth may not owe its origin to this celestial source.

The first and most important truth with regard to[276] the recurrence of the meteors is their occasional appearance in what are known as "meteoric showers." During such displays it sometimes happens that shooting stars in shoals break forth simultaneously, so as to produce a spectacle which we now regard as of the utmost beauty and interest, but which in earlier times has often been the source of the direst terror and dismay.

Let me, for the sake of illustration, give some account of one of these great showers of shooting stars.

In the year 1866 I occupied the position of astronomer to the late Earl of Rosse. The memorable night between November 13th and 14th, 1866, was a very fine one; the moon was absent—a very important consideration in regard to the effectiveness of the display. The stars shone out clearly, and I was diligently examining some faint nebulæ in the eye-piece of the great telescope, when a sudden exclamation from the attendant caused me to look up from the eye-piece just in time to catch a glimpse of a fine shooting star, which, like a great sky-rocket, but without its accompanying noise, shot across the sky over our heads. The great shooting star which had already appeared was merely the herald announcing the advent of a mighty host. At first the meteors came singly, and then, as the hours wore on, they arrived in twos and in threes, in dozens, in scores, in hundreds. Our work at the telescope was forsaken; we went to the top of the castellated walls of the great telescope and abandoned ourselves to the enjoyment of the gorgeous spectacle.

To number the meteors baffled all our arithmetic;[277] while we strove to count on the one side many of them hurried by on the other. The vivid brilliance of the meteors was sharply contrasted with the silence of their flight. We heard on that marvelous night no sounds save those with which we were familiar. The flights of the celestial rockets were attended with no noises that we could hear. The meteors were no doubt somewhat various as to size, but the characteristic feature of this shower, as contrasted with another

great shower I have also seen, was the remarkable brilliance of the shooting stars. It was their exceptional splendor even more than their innumerable profusion that gave to the shower its peculiarity. As to the actual brilliancy of the meteors, I am enabled to give the accurate estimate made by Mr. Baxendell at Manchester, where the shower was well seen. Out of every hundred of these meteors ten were brighter than a first magnitude star, and two or three of them were brighter than Sirius. Fifteen out of each hundred were between the first and second magnitudes, and twenty-five were between the second and third magnitudes, while the remainder were smaller.

Some important facts with regard to ancient shooting-star showers have survived the thousand and one casualties to which historical records are exposed. A careful discussion of those which are sufficiently accurate to be intelligible discloses to us the startling fact that in general every thirty-three years a grand shooting-star shower has rained down on our earth. It sometimes happens that two consecutive years are rendered memorable by great showers. At present[278] the day of the year on which this particular shower is wont to appear is about the 13th November; but in earlier ages we find the date to shift slowly toward the commencement of the year. Thus the display which took place in A. D. 1698 was on the 9th of November; while, looking back still further to one of the very earliest records, viz., that of the year 934, we find the date has receded to October 14th. This change of the day on which the shower occurs is of profound theoretical importance in connection with the discovery of the orbit which these meteors pursue. The advance of the date is, however, so slow that for the past few generations, as well as for the next, we may sufficiently define this particular shower by the meteors which enliven the skies between the 12th and the 14th of November. In fact, the poetaster has parodied the well-known lines for the days of the month by a similar effort, which will serve to remind us also of another periodic shower of shooting stars which occurs in August. He writes: “If you November’s stars would see, From twelfth to fourteenth watching be. In August too stars shine from heaven, On nights between nine and eleven.”

These lines are intended to imply that the days named will usually bring, in every November, a few meteors at all events belonging to the grand shower. These are stragglers, as it were, from the mighty host which visits us three times in the century.

Astronomers have a special name for this group of November meteors. They are called the “Leonids.” To explain why this name has been given, and why it[279] is appropriate, we must dwell on an important part of the phenomena of the shower. Star map of Leo region Fig. 23.—Position of Leo, Source of the Leonids

Among the constellations there is a fine sickle-shaped group, forming a part of Leo, one of the signs of the Zodiac. That part of the sky defined by Leo is curiously related to the meteors of the 12th to the[280] 14th of November. Every shooting star truly belonging to that great shower pursued a track across the heavens, the direction of which, if carried back far enough, was always found to pierce through the sickle of Leo. Indeed, the paths of all the meteors formed a set of rays spreading away from that one point in the constellation. An invariable characteristic of this particular shower is its connection with the constellation of Leo, hence the appropriateness of the name of Leonids.

It must be borne in mind that we can never see the meteors until the fatal moment when they dive into our atmosphere. We could, indeed, at any time point our telescope to the spot in the heavens where we know the great shoal must certainly be located. But the mightiest telescope in the world does not disclose the shoal to us. In fact, we would never have seen these Leonids at all, we would never have become conscious that such a shoal of meteors existed, had it not been for a certain circumstance, which, for want of a better expression, I must speak of as accidental.

Our globe pursues a certain definite track around the sun. Year after year, with undeviating regularity, the earth performs the stages of its journey. If it reaches certain points on the 1st of January and the 12th of October in one year, then it reaches the same points on the 1st of January and the 12th of October respectively on next year, or any other year.

The Leonids and the earth have each a certain track. It might of course have happened that one of these tracks lay quite outside or quite inside the[281] other. In the case of the Leonids, it has chanced that their orbit does intersect the orbit of the earth, and to this circumstance we are indebted for the glorious displays every thirty-three years.

There are many other periodic showers of shooting stars besides those notable Leonids. None of the other showers, however, possess the same importance as the Leonids, nor do they ever manifest celestial splendor comparable with that of those of the 13th of November. The Perseids, for example, which appear from the 9th to the 11th of August, are tolerably constant in their appearance, but have little spectacular interest. There is also another shower called the Andromedes, which occurs on the 27th of November. It has produced certain displays, one of the most remarkable of which took place in 1872. The meteors were excessively numerous on that occasion, but they were so short in their paths, and so insignificant as to brilliance, that the

spectacle, though of great scientific interest, could not be compared as to splendor with that of the Leonids in 1866.

There are also several other showers which appear with greater or less regularity. Each of these possesses two distinct characteristics by which its meteors can be identified. One of these characters is the date on which the shower appears. The other is the constellation or point on the heavens from which all the meteors appear to radiate. Thus when we speak of the Andromedes on the 27th of November, we express that the shower on the 27th November comes from the part of the heavens marked by the constellation of Andromeda.

[282]

A striking discovery has been made which points to a curious connection between comets and shooting stars. It has been found that the track followed by a great shower of meteors is often identical with the track pursued by a comet. It is wholly beyond the province of mere chance that an orbit such as that of the Leonids should, both as to its size and its position in space, be likewise that of a comet, unless the comet and the meteor swarm were objects related to each other.

The great sun guides our world through its long annual journey. The mighty mass of the earth yields compliance to the potent sway of the ruler of our system. But the sun does not merely exercise a control over the vast planets which circulate around him. The supreme law of gravitation constrains the veriest mote that ever floated in a sunbeam, with the same unremitting care that it does the mightiest of planets. Thus it is that each little meteor is guided in its journeys for untold ages. Each of these little objects hurries along, deflected at every moment, to follow its beautifully curved path by the incessant attraction of the sun. At last, however, the fatal plunge is taken. The long wanderings of the meteor have come to an end and it vanishes in a streak of splendor.
COMETS.—Sir John Herschel

The extraordinary aspect of comets, their rapid and seemingly irregular motions, the unexpected manner in which they often burst upon us, and the imposing magnitudes which they occasionally[283] assume, have in all ages rendered them objects of astonishment, not unmixed with superstitious dread to the uninstructed, and an enigma to those most conversant with the wonders of creation and the operations of natural causes. Even now, that we have ceased to regard their movements as irregular, or as governed by other laws than those which retain the planets in their orbits, their intimate nature, and the offices they perform in the economy of our system, are as much unknown as ever. No distinct and satisfactory account has yet been rendered of those immensely voluminous appendages which they bear about with them, and which are known by the name of their tails (though improperly, since they often precede them in their motions), any more than of several other singularities which they present.

The number of comets which have been astronomically observed, or of which notices have been recorded in history, is very great, amounting to several hundreds, and when we consider that in the earlier ages of astronomy, and indeed in more recent times, before the invention of the telescope, only large and conspicuous ones were noticed; and that, since due attention has been paid to the subject, scarcely a year has passed without the observation of one or two of these bodies, and that sometimes two and even three have appeared at once; it will be easily supposed that their actual number must be at least many thousands. Multitudes, indeed, must escape all observation, by reason of their paths traversing only that part of the heavens which is above the horizon in the daytime. Comets so circumstanced[284] can only become visible by the rare coincidence of a total eclipse of the sun—a coincidence which happened, as related by Seneca, sixty-two years before Christ, when a large comet was actually observed very near the sun. Several, however, stand on record as having been bright enough to be seen with the naked eye in the daytime, even at noon and in bright sunshine. Such were the comets of 1402, 1532 and 1843, and that of 43 B. C. which appeared during the games celebrated by Augustus in honor of Venus shortly after the death of Cæsar, and which the flattery of poets declared to be the soul of that hero taking its place among the divinities.

Comets consist for the most part of a large and more or less splendid but ill-defined nebulous mass of light called the head, which is usually much brighter toward its centre, and offers the appearance of a vivid nucleus, like a star or planet. From the head, and in a direction opposite to that in which the sun is situated from the comet, appear to diverge two streams of light, which grow broader and more diffused at a distance from the head, and which most commonly close in and unite at a little distance behind it, but sometimes continue distinct for a great part of their course; producing an effect like that of the trains left by some bright meteors, or like the diverging fire of a sky-rocket (only without sparks or perceptible motion). This is the tail. This magnificent appendage attains occasionally an immense apparent length. Aristotle relates of the tail of the comet of 371 B. C., that it occupied a third of the[285] hemisphere, or 60°; that of A. D. 1618 is stated to have been attended by a train no less than 104° in length. The comet of 1680, the most celebrated of modern times, and on many accounts the most remarkable of all, with a head not exceeding in brightness a

star of the second magnitude, covered with its tail an extent of more than 70° of the heavens, or, as some accounts state, 90°; that of the comet of 1769 extended 97°, and that of the comet of 1843 was estimated at about 65° when longest.

The tail is, however, by no means an invariable appendage of comets. Many of the brightest have been observed to have short and feeble tails, and a few great comets have been entirely without them. Those of 1585 and 1763 offered no vestige of a tail; and Cassini describes the comets of 1665 and 1682 as being as round and as well defined as Jupiter. On the other hand, instances are not wanting of comets furnished with many tails or streams of diverging light. That of 1744 had no less than six, spread out like an immense fan, extending to a distance of nearly 30° in length. The small comet of 1823 had two, making an angle of about 160°, the brighter turned as usual from the sun, the fainter toward it, or nearly so. The tails of comets, too, are often somewhat curved, bending, in general, toward the region which the comet has left, as if moving somewhat more slowly, or as if resisted in their course.

The smaller comets, such as are visible only in telescopes, or with difficulty by the naked eye, and which are by far the most numerous, offer very frequently no appearance of a tail, and appear only[286] as round or somewhat oval vaporous masses, more dense toward the centre, where, however, they appear to have no distinct nucleus, or anything which seems entitled to be considered as a solid body. This was shown in a very remarkable manner in the case of the comet discovered by Miss Mitchell in 1847, which on the 5th of October in that year passed centrally over a star of the fifth magnitude: so centrally that with a magnifying power of 100 it was impossible to determine in which direction the extent of the nebulosity was greatest. The star's light seemed in no degree enfeebled; yet such a star would be completely obliterated by a moderate fog, extending only a few yards from the surface of the earth. And since it is an observed fact that even those larger comets which have presented the appearance of a nucleus have yet exhibited no phases, though we can not doubt that they shine by the reflected solar light, it follows that even these can only be regarded as great masses of thin vapor, susceptible of being penetrated through their whole substance by the sun-beams, and reflecting them alike from their interior parts and from their surfaces. Nor will any one regard this explanation as forced, or feel disposed to resort to a phosphorescent quality in the comet itself, to account for the phenomena in question, when we consider the enormous magnitude of the space thus illuminated, and the extremely small mass which there is ground to attribute to these bodies. It will then be evident that the most unsubstantial clouds which float in the highest regions of our atmosphere, and seem at sunset to be drenched in light, and to[287] glow throughout their whole depth as if in actual ignition, without any shadow or dark side, must be looked upon as dense and massive bodies compared with the filmy and all but spiritual texture of a comet. Accordingly, whenever powerful telescopes have been turned on these bodies, they have not failed to dispel the illusion which attributes solidity to that more condensed part of the head which appears to the naked eye as a nucleus; though it is true that in some a very minute stellar point has been seen, indicating the existence of something more substantial. Fig. 24.—Head of Comet

That the luminous part of a comet is something in the nature of a smoke, fog, or cloud, suspended in a transparent atmosphere, is evident from a fact which has been often noticed, viz., that the portion of the tail where it comes closest to and surrounds the head is yet separated from it by an interval less luminous, as if sustained and kept off from contact by a transparent stratum, as we often see one layer of clouds over another with a considerable clear space between. These, and most of the other facts observed in the history of comets, appear to indicate that the structure of a comet, as seen in section in the direction of its length, must be that of a hollow envelope, of a parabolic form, inclosing near its vertex the[288] nucleus and head, something as represented in the preceding figure. This would account for the apparent division of the tail into two principal lateral branches, the envelope being oblique to the line of sight at its borders, and therefore a greater depth of illuminated matter being there exposed to the eye. In all probability, however, they admit great varieties of structure, and among them may very possibly be bodies of widely different physical constitution, and there is no doubt that one and the same comet at different epochs undergoes great changes, both in the disposition of its materials and in their physical state.

We come now to speak of the motions of comets. These are apparently most irregular and capricious. Sometimes they remain in sight only for a few days, at others for many months; some move with extreme slowness, others with extraordinary velocity; while not infrequently the two extremes of apparent speed are exhibited by the same comet in different parts of its course. The comet of 1472 described an arc of the heavens of 40° of a great circle in a single day. Some pursue a direct, some a retrograde, and others a tortuous and very irregular course; nor do they confine themselves, like the planets, within any certain region of the heavens, but traverse indifferently every part. Their variations in apparent size, during the time they continue visible, are no less remarkable than those of their velocity; sometimes they make their first appearance as faint and slow-moving objects, with little or no tail; but by degrees accelerate, enlarge, and throw out from them this appendage,[289] which increases in length and brightness till (as always

happens in such cases) they approach the sun, and are lost in his beams. After a time they again emerge on the other side, receding from the sun with a velocity at first rapid, but gradually decaying. It is for the most part after thus passing the sun that they shine forth in all their splendor, and that their tails acquire their greatest length and development; thus indicating plainly the action of the sun's rays as the exciting cause of that extraordinary emanation. As they continue to recede from the sun, their motion diminishes and the tail dies away, or is absorbed into the head, which itself grows continually feebler, and is at length altogether lost sight of, in by far the greater number of cases never to be seen more.

Without the clew furnished by the theory of gravitation, the enigma of these seemingly irregular and capricious movements might have remained forever unresolved. But Newton, having demonstrated the possibility of any conic section whatever being described about the sun, by a body revolving under the dominion of that law, immediately perceived the applicability of the general proposition to the case of cometary orbits; and the great comet of 1680, one of the most remarkable on record, both for the immense length of its tail and for the excessive closeness of its approach to the sun (within one-sixth of the diameter of that luminary), afforded him an excellent opportunity for the trial of his theory. The success of the attempt was complete. From that time it became a received truth, that the motions of comets are[290] regulated by the same general laws as those of the planets. Drawing of comet orbit Fig. 25.—Orbit of Newton's Comet (1680)

Now calculations lead to the surprising fact, that the comets are by far the most voluminous bodies in our system. The following are the dimensions of some of those which have been made the subjects of such inquiry.

The tail of the great comet of 1680, immediately after its perihelion passage, was found by Newton to have been no less than 20,000,000 of leagues in length, and to have occupied only two days in its emission from the comet's body! a decisive proof[291] this of its being darted forth by some active force, the origin of which, to judge from the direction of the tail, must be sought in the sun itself. Its greatest length amounted to 41,000,000 leagues, a length much exceeding the whole interval between the sun and earth. The tail of the comet of 1769 extended 16,000,000 leagues, and that of the great comet of 1811, 36,000,000. The portion of the head of this last, comprised within the transparent atmospheric envelope which separated it from the tail, was 180,000 leagues in diameter. It is hardly conceivable that matter once projected to such enormous distances should ever be collected again by the feeble attraction of such a body as a comet—a consideration which accounts for the surmised progressive diminution of the tails of such as have been frequently observed.

The most remarkable of those comets which have been ascertained to move in elliptic orbits is that of Halley, so called from the celebrated Edmund Halley, who, on calculating its elements from its perihelion passage in 1682, when it appeared in great splendor, with a tail 30° in length, was led to conclude its identity with the great comets of 1531 and 1607, whose elements he had also ascertained. The intervals of these successive apparitions being 75 and 76 years, Halley was encouraged to predict its reappearance about the year 1759. So remarkable a prediction could not fail to attract the attention of all astronomers, and, as the time approached, it became extremely interesting to know whether the attractions of the larger planets might not materially[292] interfere with its orbital motion. The computation of their influence from the Newtonian law of gravity, a most difficult and intricate piece of calculation, was undertaken and accomplished by Clairaut, who found that the action of Saturn would retard its return by 100 days, and that of Jupiter by no less than 518, making in all 618 days, by which the expected return would happen later than on the supposition of its retaining an unaltered period—and that, in short, the time of the expected perihelion passage would take place within a month, one way or other, of the middle of April, 1759. It actually happened on the 12th of March in that year. Its next return was calculated by several eminent geometers, and fixed successively for the 4th, the 7th, the 11th, and the 26th of November, 1835; the two latter determinations appearing entitled to the higher degree of confidence, owing partly to the more complete discussion bestowed on the observations of 1682 and 1759, and partly to the continually improving state of our knowledge of the methods of estimating the disturbing effect of the several planets. The last of these predictions, that of M. Lehmann, was published on the 25th of July. On the 5th of August the comet first became visible in the clear atmosphere of Rome as an exceedingly faint telescopic nebula, within a degree of its place as predicted by M. Rosenberger for that day. On or about the 20th of August it became generally visible, and, pursuing very nearly its calculated path among the stars, passed its perihelion on the 16th of November; after which, its course carrying it south, it ceased to be[293] visible in Europe, though it continued to be conspicuously so in the Southern Hemisphere throughout February, March, and April, 1836, disappearing finally on the 5th of May. Drawing of conic paths Fig. 26.—Forms of Cometary Orbits

Its first appearance, while yet very remote from the sun, was that of a small round or somewhat oval nebula, quite destitute of tail, and having a minute point of more concentrated light eccentrically situated within it. It was not before the 2d of October that the tail began to be developed, and thenceforward[294] increased pretty rapidly, being already 4° or 5° long on the 5th. It attained its

greatest apparent length (about 20°) on the 15th of October. From that time, though not yet arrived at its perihelion, it decreased with such rapidity that already on the 29th it was only 3°, and on November the 5th 2½° in length. There is every reason to believe that before the perihelion, the tail had altogether disappeared, as, though it continued to be observed at Pulkowa up to the very day of its perihelion passage, no mention whatever is made of any tail being then seen.

Reflecting on these phenomena, and carefully considering the evidence afforded by the numerous and elaborately executed drawings which have been placed on record by observers, it seems impossible to avoid the following conclusions: 1st. That the matter of the nucleus of a comet is powerfully excited and dilated into a vaporous state by the action of the sun's rays, escaping in streams and jets at those points of its surface which oppose the least resistance, and in all probability throwing that surface or the nucleus itself into irregular motions by its reaction in the act of so escaping, and thus altering its direction.

2. That this process chiefly takes place in that portion of the nucleus which is turned toward the sun; the vapor escaping chiefly in that direction.

3. That when so emitted, it is prevented from proceeding in the direction originally impressed upon it by some force directed from the sun, drifting it back and carrying it out to vast distances behind the nucleus, forming the tail or so much of the tail as[295] can be considered as consisting of material substance.

4th. That this force, whatever its nature, acts unequally on the materials of the comet, the greater portion remaining unvaporized, and a considerable part of the vapor actually produced remaining in its neighborhood, forming the head and coma.

5th. That the force thus acting on the materials of the tail can not possibly be identical with the ordinary gravitation of matter, being centrifugal or repulsive, as respects the sun, and of an energy very far exceeding the gravitating force toward that luminary. This will be evident if we consider the enormous velocity with which the matter of the tail is carried backward, in opposition both to the motion which it had as part of the nucleus and to that which it acquired in the act of its emission, both which motions have to be destroyed in the first instance, before any movement in the contrary direction can be impressed.

6th. That unless the matter of the tail thus repelled from the sun be retained by a peculiar and highly energetic attraction to the nucleus, differing from and exceptional to the ordinary power of gravitation, it must leave the nucleus altogether; being in effect carried far beyond the coercive power of so feeble a gravitating force as would correspond to the minute mass of the nucleus; and it is therefore very conceivable that a comet may lose, at every approach to the sun, a portion of that peculiar matter, whatever it be, on which the production of its tail depends, the remainder being of course less excitable[296] by the solar action, and more impassive to his rays, and therefore, pro tanto, more nearly approximating to the nature of the planetary bodies.

7th. That, considering the immense distances to which at least some portion of the matter of the tail is carried from the comet, and the way in which it is dispersed through the system, it is quite inconceivable that the whole of that matter should be reabsorbed—that therefore it must lose during its perihelion passage some portion of its matter, and if, as would seem far from improbable, that matter should be of a nature to be repelled from, not attracted by, the sun, the remainder will, by consequence, be, pro quantitate inertiæ, more energetically attracted to the sun than the mean of both. If then the orbit be elliptic, it will perform each successive revolution in a shorter time than the preceding, until, at length, the whole of the repulsive matter is got rid of. Drawing of the orbit Fig. 27.—Halley's Comet

Besides the comet of Halley, several other of the great comets recorded in history have been surmised with more or less probability to return periodically, and therefore to move in elongated ellipses around the sun. Such is the great comet of 1680, whose period is estimated at 575 years, and which has been considered, with at least a high prima facie probability, to be identical with a magnificent comet observed at Constantinople and in Palestine, and referred by contemporary historians, both European and Chinese, to the year A. D. 1106; with that of A. D. 531, which was seen at noonday close to the sun; with the comet of 43 B. C., already spoken of as having appeared[297] after the death of Cæsar, and which was also observed in the daytime; and finally with two other comets, mention of which occurs in the Sibylline Oracles, and in a passage of Homer, and which are referred, as well as the obscurity of chronology and the indications themselves will allow, to the years 618 and 1194 B. C. It is to the assumed near approach of this comet to the earth, about the time of[298] the Deluge, that Whiston ascribed that overwhelming tide-wave to whose agency his wild fancy ascribed that great catastrophe—a speculation, it is needless to remark, purely visionary. These coincidences of time are certainly remarkable, especially when it is considered how very rare are the appearances of comets of this class. Professor Encke, however, has discussed, with all possible care, the observations recorded of the comet of 1680, taking into consideration the perturbations of the planets (which are of trifling importance, by reason of the great inclination of its orbit to the

ecliptic), and his calculations show that no elliptic orbit, with such a period as 575 years, is competent to represent them within any probable or even possible limits of error, the most probable period assigned by them being 8814 Julian years. Independent of this consideration, there are circumstances recorded of the comet of A. D. 1106 incompatible with its motion in any orbit identical with that of the comet of 1680, so that the idea of referring all these phenomena to one and the same comet, however seducing, must be relinquished.

Another great comet, whose return about the year 1848 had been considered by more than one eminent authority in this department of astronomy highly probable, is that of 1556, to the terror of whose aspect some historians have attributed the abdication of the Emperor Charles V. This comet is supposed to be identical with that of 1264, mentioned by many historians as a great comet, and observed also in China.

In 1661, 1532, 1402, 1145, 891, and 243 great comets appeared—that of 1402 being bright enough to[299] be seen at noonday. A period of 129 years would conciliate all these appearances, and should have brought back the comet in 1789 or 1790 (other circumstances agreeing). That no such comet was observed about that time is no proof that it did not return, since, owing to the situation of its orbit, had the perihelion passage taken place in July it might have escaped observation.

We come now, however, to a class of comets of short period, respecting whose return there is no doubt, inasmuch as two at least of them have been identified as having performed successive revolutions round the sun; have had their return predicted already several times; and have on each occasion scrupulously kept to their appointments. The first of these is the comet of Encke, so called from Professor Encke of Berlin, who first ascertained its periodical return. It revolves in an ellipse of great eccentricity (though not comparable to that of Halley's), the plane of which is inclined at an angle of about 13° 22′ to the plane of the ecliptic, and in the short period of 1,211 days, or about 3■ years. This remarkable discovery was made on the occasion of its fourth recorded appearance, in 1819. From the ellipse then calculated by Encke, its return in 1822 was predicted by him, and observed at Paramata, in New South Wales, by M. Rümker, being invisible in Europe: since which it has been repredicted and reobserved in all the principal observatories, both in the Northern and Southern Hemispheres, as a phenomenon of regular occurrence.

Another comet of short period is that of Biela,[300] so called from M. Biela of Josephstadt, who first arrived at this interesting conclusion on the occasion of its appearance in 1826. It is considered to be identical with comets which appeared in 1772, 1805, etc., and describes its very eccentric ellipse about the sun in 2,410 days, or about 6¾ years; and in a plane inclined 12° 34′ to the ecliptic. It appeared again, according to the prediction, in 1832 and in 1846.

This comet is small and hardly visible to the naked eye, even when brightest. Nevertheless, as if to make up for its seeming insignificance by the interest attaching to it in a physical point of view, it exhibited, at its appearance in 1846, a phenomenon which struck every astronomer with amazement, as a thing without previous example in the history of our system. It was actually seen to separate itself into two distinct comets, which, after thus parting company, continued to journey along amicably through an arc of upward of 70° of their apparent orbit, keeping all the while within the same field of view of the telescope pointed toward them. The first indication of something unusual being about to take place might be, perhaps, referred to the 19th of December, 1845, when the comet appeared to Mr. Hind pear-shaped, the nebulosity being unduly elongated in a direction inclining northward. But on the 13th of January, at Washington, in America, and on the 15th and subsequently in every part of Europe, it was distinctly seen to have become double; a very small and faint cometic body, having a nucleus of its own, being observed appended to it, at a distance of about 2′ (in arc) from its centre, and[301] in a direction forming an angle of about 328° with the meridian, running northward from the principal or original comet. From this time the separation of the two comets went on progressively, though slowly. On the 30th of January the apparent distance of the nucleus had increased to 3′, on the 7th of February to 4′, and on the 13th to 5′, and so on, until on the 5th of March the two comets were separated by an interval of 9′ 19″, the apparent direction of the line of junction all the while varying but little with respect to the parallel.

During this separation, very remarkable changes were observed to be going on, both in the original comet and its companion. Both had nuclei, both had short tails, parallel in direction and nearly perpendicular to the line of junction; but whereas at its first observation, on January 13th, the new comet was extremely small and faint in comparison with the old, the difference both in point of light and apparent magnitude diminished. On the 10th of February they were nearly equal, although the day before the moonlight had effaced the new one, leaving the other bright enough to be well observed. On the 14th and 16th, however, the new comet had gained a decided superiority of light over the old, presenting at the same time a sharp and star-like nucleus, compared by Lieutenant Maury to a diamond spark. But this state of things was not to continue. Already, on the 18th, the old comet had regained its superiority, being nearly twice as bright as its companion, and offering an unusually bright and star-like nucleus. From this period

the new companion began to fade[302] away, but continued visible up to the 15th of March. On the 24th the comet appeared again single, and on the 22d of April both had disappeared.

While this singular interchange of light was going forward, indications of some sort of communication between the comets were exhibited. The new or companion comet, besides its tail, extending in a direction parallel to that of the other, threw out a faint arc light which extended as a kind of bridge from the one to the other; and after the restoration of the original comet to its former pre-eminence, it, on its part, threw forth additional rays, so as to present the appearance of a comet with three faint tails forming angles of about 120° with each other, one of which extended toward its companion.

On the 22d of August, 1844, Signor de Vico, director of the observatory of the Collegio Romano, discovered a comet, the motions of which, a very few observations sufficed to show, deviated remarkably from a parabolic orbit. It passed its perihelion on the 2d of September, and continued to be observed until the 7th of December. Elliptic elements of this comet, agreeing remarkably well with each other, were accordingly calculated by several astronomers, from which it appears that the period of revolution is about 1,990 days, or 5½ (5.4357) years, which (supposing its orbit undisturbed in the interim) would bring it back to the perihelion on or about the 13th of January, 1850, on which occasion, however, by reason of its unfavorable situation with respect to the sun and earth, it could not be observed.

This comet, when brightest, was visible to the[303] naked eye, and had a small tail. It is especially interesting to astronomers from the circumstance of its having been rendered exceedingly probable by the researches of M. Leverrier, that it is identical with one which appeared in 1678, with some of its elements considerably changed by perturbation. This comet is further remarkable from having been concluded, by Messrs. Laugier and Mauvais, to be identical with the comet of 1585 observed by Tycho Brahe, and possibly also with those of 1743, 1766, and 1819.

By far the most remarkable comet, however, which has been seen during the present century, is that which appeared in the spring of 1843, and whose tail became visible in the twilight of the 17th of March in England as a great beam of nebulous light, extending from a point above the western horizon, through the stars of Eridanus and Lepus, under the belt of Orion. This situation was low and unfavorable; and it was not till the 19th that the head was seen, and then only as a faint and ill-defined nebula, very rapidly fading on subsequent nights. In more southern latitudes, however, not only the tail was seen, as a magnificent train of light extending 50° or 60° in length; but the head and nucleus appeared with extraordinary splendor, exciting in every country where it was seen the greatest astonishment and admiration. Indeed, all descriptions agree in representing it as a stupendous spectacle, such as in superstitious ages would not fail to have carried terror into every bosom. In tropical latitudes in the Northern Hemisphere, the tail appeared on the 3d of[304] March, and in Van Diemen's Land so early as the 1st, the comet having passed its perihelion on the 27th of February.

There is abundant evidence of the comet in question having been seen in full daylight, and in the sun's immediate vicinity. It was so seen on the 28th of February, the day after its perihelion passage, by every person on board the H.E.I.C.S. "Owen Glenndower," then off the Cape, as a short dagger-like object close to the sun a little before sunset. On the same day at 3h 6m P. M., and consequently in full sunshine, the distance of the nucleus from the sun was actually measured with a sextant by Mr. Clarke of Portland, United States, the distance centre from centre being then only 3° 50′ 43″. Drawing of orbits Fig. 28.—Orbits of the Nine Comets Captured by Jupiter Scale: 5 millimetres = 1 radius of the Earth's orbit

It is by no means merely as a subject of antiquarian interest, or on account of the brilliant spectacle which comets occasionally afford, that astronomers attach a high degree of importance to all that regards them. Apart even from the singularity and mystery which appertains to their physical constitution, they have become, through the medium of exact calculation, unexpected instruments of inquiry into points connected with the planetary system itself, of no small importance. We have seen that the movements of the comet Encke, thus minutely and perseveringly traced by the eminent astronomer whose name is used to distinguish it, have afforded ground for believing in the presence of a resisting medium filling the whole of our system. Similar inquiries, prosecuted in the cases of other periodical comets, will extend, confirm, or modify our conclusions[305] on this head. The perturbations, too, which comets experience in passing near any of the planets, may afford, and have afforded, information as to the magnitude of the disturbing masses, which could not well be otherwise obtained. Thus the approach of this comet to the planet Mercury in 1838 afforded an estimation of the mass of that planet the more precious, by reason of the great uncertainty under which all previous determinations of that element labored. Its approach to the same planet in the[306] year 1848 was still nearer. On the 22d of November their mutual distance was only fifteen times the moon's distance from the earth.

It is, however, in a physical point of view that these bodies offer the greatest stimulus to our curiosity. There is, beyond question, some profound secret and mystery of nature concerned in the phenomenon of their tails. Perhaps it is not too much to hope that future observation, borrowing every aid from rational speculation, grounded on the progress of physical science generally (especially those branches of it which relate to the ethereal or imponderable elements), may ere long enable us to penetrate this mystery, and to declare whether it is really matter in the ordinary acceptation of the term which is projected from their heads with such extravagant velocity, and if not impelled, at least directed, in its course by a reference to the sun, as its point of avoidance. In no respect is the question as to the materiality of the tail more forcibly pressed on us for consideration than in that of the enormous sweep which it makes round the sun in perihelio, in the manner of a straight and rigid rod, in defiance of the law of gravitation, nay, even of the received laws of motion, extending (as we have seen in the comets of 1680 and 1843) from near the sun's surface to the earth's orbit, yet whirled round unbroken: in the latter case through an angle of 180° in little more than two hours. It seems utterly incredible that in such a case it is one and the same material object which is thus brandished. If there could be conceived such a thing as a negative shadow, a momentary impression[307] made upon the luminiferous ether behind the comet, this would represent in some degree the conception such a phenomenon irresistibly calls up. But this is not all. Even such an extraordinary excitement of the ether, conceive it as we will, will afford no account of the projection of lateral streamers; of the effusion of light from the nucleus of a comet toward the sun; and its subsequent rejection; of the irregular and capricious mode in which that effusion has been seen to take place; none of the clear indications of alternate evaporation and condensation going on in the immense regions of space occupied by the tail and coma—none, in short, of innumerable other facts which link themselves with almost equally irresistible cogency to our ordinary notions of matter and force. LIFE IN OTHER WORLDS.—J. E. Gore

The question is often asked, Are the stars inhabited? To this we can confidently answer, No. The stars themselves are certainly not habitable by any forms of life with which we are familiar. That the stars are luminous incandescent bodies, similar to the sun, seems almost self-evident. That they shine by their own inherent light, and not by light reflected from another body, like the planets of the Solar System, is a fact which scarcely needs demonstration. There are no bright objects near them from which they could derive their light, and they are too far from the sun to obtain any illumination[308] from that source. But if any proofs were necessary, we have the evidence of the spectroscope, which shows unmistakably that their light emanates from incandescent bodies. Many of the stars show spectra very similar to that of the sun. The light of others, although differing somewhat in quality when analyzed by the prism, indicates clearly that they are at a very high temperature—in many cases, indeed, suggesting that they are actually hotter than the sun. It may be objected, however, that in the case of binary or revolving double stars, the smaller component may possibly shine by light reflected from the brighter star. Indeed, this has been suggested in the case of Sirius and its faint companion. But, if the companion of Sirius shone merely by reflected light from its primary, it would be much fainter than it is, and, indeed, would be utterly invisible in our largest telescopes. Further, in some double stars, spectroscopic observations suggest that the component stars have different spectra. This is, of course, conclusive evidence against the hypothesis of borrowed light; for were the smaller star to shine by reflected light from the larger, the spectra of both would be identical, as in the case of the sun and moon. We may therefore conclude that all the visible stars are suns, and totally unfit for the habitation of living creatures.

But may not the stars have planets revolving round them, forming solar systems similar to our own? As they are evidently suns shining by inherent light, may they not form centres of planetary systems? In the case of those stars having spectra differing from[309] the solar spectrum, we can not speak with any confidence; but for those which show spectra similar to that of our sun, and having, therefore, probably a similar chemical constitution, the existence of planets revolving round them seems from analogy very probable. I refer to single stars, that is stars which have no telescopic close companion; for the double stars may, perhaps, form systems differently constituted. In any case these binary systems would not be strictly comparable with ours, for the sun is certainly a single star.

Whether systems of planets really revolve round the stars referred to, is a question which, unfortunately, can not be decided by observation. If a planet equal in size to the "giant planet," Jupiter, were revolving round the nearest star—Alpha Centauri—at the same distance from that star that Jupiter is from the sun, it would be utterly invisible in our largest telescopes. The invisibility of planets circling round the stars is therefore no proof whatever of their non-existence. Each star of the solar type may possibly be attended by a retinue of planets which may, perhaps, remain forever invisible in the largest telescopes which man can construct. We can, therefore, draw our conclusions only from analogy. If other suns exist resembling our own sun in chemical constitution, which we know to be a fact, is it not reasonable to suppose that they also form centres of planetary systems similar to the Solar System? "Consult with reason, reason will reply, Each lucid point which glows in yonder sky, Informs a system in the boundless space, And fills with glory its appointed place; [310] With beams unborrowed brighten other skies, And worlds to the unknown with heat and light supplies."

The suns, which we call stars, were clearly not created for our benefit. They are of very little practical use to the earth's inhabitants. They give us very little light; an additional small satellite—one considerably smaller than the moon—would have been much more useful in this respect than the millions of suns revealed by the telescope. They must, therefore, have been formed for some other purpose.

On Laplace's Nebular Hypothesis, the condensation of an original nebulous mass endowed with a motion of rotation would result not only in the formation of a sun, similar to ours, but also in a system of planets revolving round the central body. If, indeed, the primitive nebula had no rotation or motions of any kind, the result would be a sun without planets or satellites; but the motions with which all the stars seem to be animated lead us to suppose that this would be a case of very rare occurrence. We may therefore conclude, with a high degree of probability, that the stars—at least those with spectra of the solar type—form centres of planetary systems somewhat similar to our own.

This being surmised, let us consider the conditions necessary for the existence of life on these planets. There are various conditions which must be complied with before we can imagine life, as we know it, to be possible on any planet. Perhaps the most important of these is the question of temperature. We know that in the universe a great range of temperature[311] exists, from the cold of interstellar space—estimated at about 460° below the freezing-point of water—to the intense heat which rages in the solar photosphere. In this long thermal scale life is, at least on the earth, restricted within rather narrow limits. Below a certain low temperature life can not exist. The point is, however, far above the temperature of space. On the other hand, above a certain high temperature—a low one, however, compared with the intense heat of the solar surface—life is also impossible, at least for highly organized beings like man and the larger animals. For minute microscopic organisms the scale may, perhaps, be somewhat extended; but even in its widest limits, the range of temperature within which life is possible is, so far as we know, certainly a narrow one.

For the support of life and vegetation, light is also necessary, for without it no flowers would bloom, nor corn grow and ripen to maturity. To obtain this supply of light and heat it is necessary that a life-bearing planet should revolve at a suitable distance from, and in a nearly circular orbit round, a central sun. These conditions, it is hardly necessary to say, are fulfilled in the case of the earth. Were we much nearer to the sun than we are, we should suffer from excessive heat, and were we much further away, we should probably perish from the cold. For this reason the existence of life on the other planets of the Solar System seems very doubtful. Mercury is probably too hot, and the other planets are certainly too cold, so far as heat from[312] the sun is concerned, unless, indeed, their internal heat is sufficient to raise the temperature of their surface to a point sufficient for the maintenance of life. Indeed, there is good reason to suppose that in the planets Jupiter, Saturn, Uranus, and Neptune, this internal heat is still so great that life would be quite impossible on their surface. Venus, inside the earth's orbit, and Mars, outside, are the two planets which seem to approach nearest to the required conditions. We know that both these planets possess atmospheres somewhat similar to ours, and, in Mars at least, land and water most probably exist on its surface. Venus is, of course, much hotter than the earth, and Mars much colder, but possibly the polar regions of Venus and the equatorial regions of Mars may form suitable abodes for some forms, at least, of animal and vegetable life.

Let us proceed, however, to consider some other conditions necessary for the existence of life on a planet. A suitable temperature is, of course, indispensable, but this is not all. There are other conditions which must be complied with. The planet must have a rotation on its axis, so that every portion shall in turn receive its due share of light and heat. Each point on its surface must have its day and night, the day for work and the night for rest. The axis of rotation must not lie in the plane of the planet's orbit, but must have a suitable inclination, so that each hemisphere may enjoy its seasons, summer and winter, "seed-time and harvest," in due course. Further the velocity of rotation on its axis must not be too rapid. If the earth rotated in a period of one[313] and a quarter hours, bodies at the equator would have no weight, and life would be impossible in those regions.

The planet must also possess a mass sufficient to retain bodies on its surface by the force of gravity. In the case of very small bodies, such as the moons of Mars and some of the minor planets between Mars and Jupiter, objects thrown into the air would pass away into space never to return.

The planet should also have a mean density greater than that of water, otherwise the seas would possess no stability, and destructive waves would quickly destroy all life on its surface. All these conditions are fulfilled in the case of Mars as well as on the earth. In the planet Saturn, however, the density is less than that of water, and in Uranus and Neptune only slightly greater.

The planet must also possess a suitable atmosphere. This is an all-important condition for the support of animal life—at least for the existence of man and the higher orders of animals. This atmosphere must consist—so far as we know—of oxygen and nitrogen gases mechanically mixed in proper proportions, and with a small quantity of carbonic acid gas. Were the oxygen in smaller quantity than it exists in the earth's atmosphere, life could not be supported. On the other hand, were it much in excess of its present amount, a fever would be produced in the blood which would very soon put an end to animal life. The presence of other gases in excessive quantities would also render the air unfit for breathing. We see, therefore, that a comparatively slight[314] change in the composition of a planet's atmosphere would—so far as our experience goes—render the planet uninhabitable by any of the higher forms of life with which we are familiar.

For the support of life on a planet, water is also absolutely necessary. Without this useful fluid the world would soon become a desert, and life and vegetation would speedily vanish from its surface.

Geological conditions must also be considered. It is clearly necessary for the welfare of human beings at least that the surface soil and rocks should contain coal, iron, lime, and other minerals, substances almost indispensable for the ordinary wants of civilized existence. Drawings of a Martian region Nine Views of the Hour-Glass Sea on Mars 1, Nov. 26, 1864; 2, June 29, 1873; 3, Oct. 28, 1879; 4, June 2, 1888; 5, June 20, 1890; 6, Aug. 6, 1892; 7, Oct., 1894; 8, Dec. 3, 1896; 9, Dec. 7, 1896

That all or any of the conditions considered would be complied with in the case of a planet revolving round a star it is, of course, impossible to say. But when we find stars showing by their spectra that they contain chemical elements identical with those which exist in the sun and the earth, analogy would lead us to suppose that very possibly a planet resembling our earth may revolve round each of these distant suns. I say a planet, for evidently there would be only one distance from the central luminary—a distance depending on its size—at which the temperature necessary for the support of life would exist, as in the case of the earth, over the whole of the planet's surface. For other planets of the stellar system, life would be, if it existed at all, most probably confined to restricted regions of the planet's surface. There would, therefore, be in each system one planet, and only one,[315] especially suitable for the support of animal life as we know it. This is with reference to light and heat. If the other conditions were not complied with, then life would probably not exist even on this one planet. In the case of a star larger than the sun, the planet should be placed at a greater distance than the earth is from the sun, but in this case the length of the year and the seasons would be longer than ours.

The star which more nearly resembles the sun in the character of the light which it emits is the bright star Capella. Arcturus has a somewhat similar spectrum. But these are probably suns of enormous size, if any reliance can be placed on the measures of their distance from the earth. Other bright stars with spectra of the solar type are Pollux, Aldebaran, Beta Andromedæ, Alpha Arietis, Alpha Cassiopeiæ, Alpha Cygni, and Alpha Ursæ Majoris. Another star is Eta Herculis. The magnitude of this star as measured with the photometer is about 3½. A parallax found by Bélopolsky and Wagner places it at a distance of 515,660 times the sun's distance from the earth. If the sun were placed at this distance, I find that it would be reduced to a star of the third magnitude. This result would imply that Eta Herculis is a slightly smaller sun than ours; and a planet placed a little nearer to the star than the earth is to the sun might, perhaps, fulfil the conditions of a life-bearing world.

The number of stars visible in our largest telescopes is usually estimated at 100,000,000. Of these we may perhaps assume that 10,000,000 have a spectrum of the solar type, and therefore closely resemble[316] our sun in their chemical constitution. If we suppose that only one in ten of these is similar in size to the sun, and has a habitable planet revolving round it, we have a total of 1,000,000 worlds in the visible universe fitted for the support of animal life.

We may therefore conclude, with a high degree of probability, that among the "multitudinous" stellar hosts there are probably many stars having life-bearing planets revolving round them. THE SUN—WHAT WE LEARN FROM IT.—Richard A. Proctor

The Sun, the central and ruling body of the planetary system, and the source of light and heat to our earth and all the members of that system, is a globe about 852,900 miles in diameter. So far as observation extends, his figure is perfectly spherical, no difference having been observed between his polar and spherical diameters. It has been well remarked, indeed, by Sir G. Airy, that if any observer could by ordinary modes of measurement satisfy himself that a real difference existed between the diameters, that observer would have proved the inexactness of his own work; for the absence of any measurable compression comes out as the result of comparisons between thousands of observations of the sun's limbs made at Greenwich and other leading observatories. The volume of the sun exceeds the earth's 1,252,700 times. His mean density is almost exactly one-fourth of the earth's, and his mass exceeds hers about 316,000 times. Gravity at the[317] surface of the sun exceeds terrestrial gravity about 27.1 times, so that

a body dropped from rest near the sun's surface would fall through 436 feet in the first second, and have acquired a velocity of 872 feet per second.

Let the reader consider a terrestrial globe three inches in diameter, and search out on that globe the tiny triangular speck which represents Great Britain. Then let him endeavor to picture the town in which he lives as represented by the minutest pin-mark that could possibly be made upon this speck. He will then have formed some conception, though but an inadequate one, of the enormous dimensions of the earth's globe, compared with the scene in which his daily life is cast. Now, on the same scale, the sun would be represented by a globe about twice the height of an ordinary sitting-room. A room about twenty-six feet in length, and height, and breadth, would be required to contain the representation of the sun's globe on this scale, while the globe representing the earth could be placed in a moderately large goblet.

Such is the body which sways the motions of the Solar System. The largest of his family, the giant Jupiter, though of dimensions which dwarf those of the earth or Venus almost to nothingness, would yet only be represented by a thirty-two inch globe, on the scale which gives to the sun the enormous volume I have spoken of. Saturn would have a diameter of about twenty-eight inches, his ring measuring about five feet in its extreme span. Uranus and Neptune would be little more than a foot in diameter,[318] and all the minor planets would be less than the three-inch earth. It will thus be seen that the sun is a worthy centre of the great scheme he sways, even when we merely regard his dimensions. Drawing of a sun spot Fig. 29.—Sun Spot seen in 1870

The sun outweighs fully seven hundred and forty times the combined mass of all the planets which circle around him, so that, when we regard the energy of his attraction, we still find him a worthy ruler of the planetary scheme.

Viewed with the naked eye, the sun appears only as a luminous mass of intense and uniform brightness; but when examined with the telescope, his surface is frequently observed to be mottled over with a number of dark spots, of irregular and ill-defined forms, constantly varying in appearance, situation,[319] and magnitude. These spots are occasionally of immense size, so as to be visible even without the aid of the telescope; and their number is frequently so great that they occupy a considerable portion of the sun's surface. Sir W. Herschel observed one in 1779 the diameter of which exceeded 50,000 miles, more than six times the diameter of the earth; and Scheiner affirms that he has seen no less than fifty on the sun's disk at once. Most of them have a deep black nucleus, surrounded by a fainter shade, or umbra, of which the inner part, nearest to the nucleus, is brighter than the exterior portion. The boundary between the nucleus and umbra is in general tolerably well defined; and beyond the umbra[320] a stripe of light appears more vivid than the rest of the sun. Drawing of a sun spot Fig. 30.—Phase of Spot

The discovery of the sun's spots has been attributed to Fabricius, Galileo, and Scheiner, and has been claimed for the English astronomer Harriot. Amid these conflicting pretensions it is perhaps impossible to arrive at the truth; but the matter is of little importance; the discovery is one which followed inevitably that of the telescope, and an accidental priority of observation can hardly be considered as establishing any claim to merit.

The study of solar physics may be said to have commenced with the discovery of the sun spots, about two hundred and sixty years ago. These spots were presently found to traverse the solar disk in such a way as to indicate that the sun turns upon an axis once in about twenty-six days. Nor will this rotation appear slow, when we remember that it implies a motion of the equatorial parts of the sun's surface at a rate exceeding some seventy times the motion of our swiftest express train.

Next came the discovery that the solar spots are not surface stains, but deep cavities in the solar substance. The changes of appearance presented by the spots as they traverse the solar disk led Dr. Wilson to form this theory so far back as 1779; but, strangely enough, it is only in comparatively recent times that the hypothesis has been finally established, since even within the last ten years a theory was put forward which accounted satisfactorily for most of the changes of appearance observed in the spots, by supposing them to be due to solar clouds[321] hanging suspended at a considerable elevation above the true photosphere.

Sir William Herschel, reasoning from terrestrial analogies, was led to look on the spot-cavities as apertures through a double layer of clouds. He argued that, were the solar photosphere of any other nature, it would be past comprehension that vast openings should form in it, to remain open for months before they close up again. Whether we consider the enormous rapidity with which the spots form and with which their figure changes, or the length of time that many of them remain visible, we find ourselves alike perplexed, unless we assume that the solar photosphere resembles a bed of clouds. Through a stratum of terrestrial clouds openings may be formed by atmospheric disturbances, but while undisturbed the clouds will retain any form once impressed upon them, for a length of time corresponding to the weeks and months during which the solar spots endure.

And because the solar spots present two distinct varieties of light, the faint penumbra and the dark umbra or nucleus, Herschel saw the necessity of assuming that there are two beds of clouds, the outer self-luminous and constituting the true solar photosphere, the inner reflecting the light received from the outer layer, and so shielding the real surface of the sun from the intense light and heat which it would otherwise receive.

But while recent discoveries have confirmed Sir William Herschel's theory about the solar cloud-envelopes, they have by no means given countenance[322] to his view that the body of the sun may possibly be cool. The darkness of the nucleus of a spot is found, on the contrary, to give proof that in that neighborhood the sun is hotter, because it parts less readily with its heat. We shall see presently how this is. Meantime let it be noticed, in passing, that a close scrutiny of large solar spots has revealed the existence of an intensely black spot in the midst of the umbra. This black spot must be regarded as the true nucleus.

The circumstance that the spots appear only on two bands of the sun's globe, corresponding to the sub-tropical zones on our own earth, led the younger Herschel to conclusions as important as those which his father had formed. He reasoned, like his father, from terrestrial analogies. On our own earth the sub-tropical zones are the regions where the great cyclonic storms have their birth, and rage with their chief fury. Here, therefore, we have the analogue of the solar spots, if only we can show reason for believing that any causes resembling those which generate the terrestrial cyclone operate upon those regions of the sun where the solar spots make their appearance.

We know that the cyclone is due to the excess of heat at the earth's equator. It is true that this excess of heat is always in operation, whereas cyclones are not perpetually raging in sub-tropical climates. Ordinarily, therefore, the excess of heat does not cause tornadoes. Certain aerial currents are generated whose uniform motion suffices, as a rule, to adjust the conditions which the excess of[323] heat at the equator would otherwise tend to disturb. But when through any cause the uniform action of the aerial currents is either interfered with or is insufficient to maintain equilibrium, then cyclonic or whirling motions are generated in the disturbed atmosphere, and propagated over a wide area of the earth's surface.

Now we recognize the reason of the excess of heat at the earth's equator in the fact that the sun shines more directly upon that part of the earth than on the zones which lie in higher latitudes. Can we find any reason for suspecting that the sun, which is not heated from without as the earth is, should exhibit a similar peculiarity? Sir John Herschel considers that we can. If the sun has an atmosphere extending to a considerable distance from his surface, then there can be little doubt that, owing to his rotation upon his axis, this atmosphere would assume the figure of an oblate spheroid, and would be deepest over the solar equator. Here, then, more of the sun's heat would be retained than at the poles, where the atmosphere is shallowest. Thus, that excess of heat at the solar equator which is necessary to complete the analogy between the sun spots and terrestrial cyclones seems satisfactorily established.

It must be remarked, however, that this reasoning, so far as the excess of heat at the sun's equator is concerned, only removes the difficulty a step. If there were indeed an increased depth of atmosphere over the sun's equator sufficing to retain the requisite excess of heat, then the amount of heat we receive[324] from the sun's equatorial regions ought to be appreciably less than the amount emitted from the remaining portions of the solar surface. This is not found to be the case, so that either there is no such excess of absorption, or else the solar equator gives out more heat, in other words, is essentially hotter, than the rest of the sun. But this is just the peculiarity of which we want the interpretation.

It may be taken for granted, however, that there is an analogy between the sun spots and terrestrial cyclonic storms, though as yet we are not very well able to understand its nature.

Then next we come to one of the most interesting discoveries ever made respecting the sun—the discovery that the spots increase and diminish in frequency in a periodic manner. We owe this discovery to the laborious and systematic observations made by Herr Schwabe of Dessau.

Schwabe found, in the course of about ten and a half years, the solar spots pass through a complete cycle of changes. They become gradually more and more numerous up to a certain maximum, and then as gradually diminish. At length the sun's face becomes not only clear of spots, but a certain well-marked darkening around the border of his disk disappears altogether for a brief season. At this time the sun presents a perfectly uniform disk. Then gradually the spots return, become more and more numerous, and so the cycle of changes is run through again.

The astronomers who have watched the sun from the Kew Observatory have found that the process of[325] change by which the spots sweep in a sort of “wave of increase” over the solar disk is marked by several minor variations. As the surface of a great sea wave will be traversed by small ripples, so the gradual increase and diminution in the number of the solar spots are characterized by minor gradations of change, which are sufficiently well marked to be distinctly cognizable. Heavenly bodies Fig. 31.—Ptolemaic System

There seems every reason for believing that the periodic changes thus noticed are due to the influence of the planets upon the solar photosphere, though in what way that influence is exerted is not at present perfectly clear. Some have thought that the mere attraction of the planets tends to produce tides of some sort in the solar envelopes. Then, since the height of a tide so produced varies as the cube or[326] third power of the distance, it has been thought that a planet when in perihelion would generate a much larger solar tide than when in aphelion. So that, as Jupiter has a period nearly equal to the sun-spot period, it has been supposed that the attractions of this planet are sufficient to account for the great spot period. Venus, Mercury, the Earth, and Saturn have, in a similar manner, been rendered accountable for the shorter and less distinctly marked periods.

Without denying that the planets may be, and probably are, the bodies to whose influence the solar-spot periods are to be ascribed, I yet venture to express very strong doubts whether the attraction of Jupiter is so much greater in perihelion than in aphelion as to account for the fact that, whereas at one season the face of the sun shows many spots, at another it is wholly free from them.[23]

However, we are not at present concerned so much with the explanation of facts as with the facts themselves. We have to consider rather what the sun is and what he does for the Solar System than why these things are so.

Let us note, before passing to other circumstances of interest connected with the sun, that the variable condition of his photosphere must cause him to change in brilliancy as seen from vast distances. If Herr Schwabe, for instance, instead of observing the[327] sun’s spots from his watch-tower at Dessau, could have removed himself to a distance so enormous that the sun’s disk would have been reduced, even in the most powerful telescope, to a mere point of light, there can be no doubt that the only effect which he would have been able to perceive would have been a gradual increase and diminution of brightness, having a period of about ten and a half years.

Our sun, therefore, viewed from the neighborhood of any of the stars, whence undoubtedly he would simply appear as one among many fixed stars, would be a “variable,” having a period of ten and a half years. And further, if an observer, viewing the sun from so enormous a distance, had the means of very accurately measuring its light, he would undoubtedly discover that, while the chief variation of the sun takes place in a period of ten and a half years, its light is subjected to minor variations having shorter periods.

The discovery that the periodic changes of the sun’s appearance are associated with the periodic changes in the character of the earth’s magnetism is the next that we have to consider.

It had long been noticed that, during the course of a single day, the magnetic needle exhibits a minute change of direction, taking place in an oscillatory manner. And, when the character of this vibration came to be carefully examined, it was found to correspond to a sort of effort on the needle’s part to turn toward the sun. For example, when the sun is on the magnetic meridian, the needle has its mean position. This happens twice in a day,[328] once when the sun is above the horizon and once when he is below it. Again, when the sun is midway between these two positions—which also happens twice in the day—the needle has its mean position, because the northern and the southern ends make equal efforts (so to speak) to direct themselves toward the sun. Four times in the day, then, the needle has its mean position, or is directed toward the magnetic meridian. But, when the sun is not in one of the four positions considered, that end of the needle which is nearest to him is slightly turned away from its mean position toward him. The change of position is very minute, and only the exact modes of observation made use of in the present age would have sufficed to reveal it. There it is, however, and this minute and seemingly unimportant peculiarity has been found to be full of meaning.

The minute vibrations of the magnetic needle, thus carefully watched—day after day, month after month, year after year—were found to exhibit a yet more minute oscillatory change. They waxed and waned within narrow limits of variation, but yet in a manner there was no mistaking. The period of this oscillatory change was not to be determined, however, by the observations of a few years. Between the time when the diurnal vibration was least until it had reached its greatest extent, and thence returned to its first value, no less than ten and a half years elapsed, and a much longer time passed before the periodic character of the change was satisfactorily determined.

The reader will at once see what these observations[329] tend to. The sun spots vary in frequency within a period of ten and a half years, and the magnetic diurnal vibrations vary within a period of the same duration. It might seem fanciful to associate the two periodic series of changes together, and doubtless when the idea first occurred to Lamont, it was not with any great expectation of finding it confirmed that he examined the evidence bearing on the point. Judging from known facts, we may see reasons for such an expectation in the correspondence of the needle's diurnal vibration with the sun's apparent motion, and the law which has been found to associate the annual variations of the magnet's power with the sun's distance. But undoubtedly when the idea occurred to Lamont it was an exceedingly bold one, and the ridicule with which the first announcement of the supposed law was received, even in scientific circles, suffices to show how unexpected that relation was which is now so thoroughly established. For a careful comparison between the two periods has demonstrated that they agree most perfectly, not merely in length, but maximum for maximum, and minimum for minimum. When the sun spots are most numerous, then the daily vibration of the magnet is most extensive, while, when the sun's face is clear of spots, the needle vibrates over its smallest diurnal arc.

Then the intensity of the magnetic action has been found to depend upon solar influences. The vibrations by which the needle indicates the progress of those strange disturbances of the terrestrial magnetism which are known as magnetic storms have[330] been found not merely to be most frequent when the sun's face is most spotted, but to occur simultaneously with the appearance of signs of disturbance in the solar photosphere. For instance, during the autumn of 1859, the eminent solar observer, Carrington, noticed the apparition of a bright spot upon the sun's surface. The light of this spot was so intense that he imagined the dark glass which protected his eye had been broken. By a fortunate coincidence, another observer, Mr. Hodgson, happened to be watching the sun at the same instant, and witnessed the same remarkable appearance. Now it was found that the self-registering magnetic instruments of the Kew Observatory had been sharply disturbed at the instant when the bright spot was seen. And afterward it was learned that the phenomena which indicate the progress of a magnetic storm had been observed in many places. Telegraphic communication was interrupted, and in some cases, telegraphic offices were set on fire; auroras appeared both in the Northern and Southern Hemisphere during the night which followed; and the whole frame of the earth seemed to thrill responsively to the disturbance which had affected the great central luminary of the Solar System. Heavenly bodies Fig. 32.—Copernican System: Facsimile of the Drawing in the Volume by Copernicus Published in 1543

The reader will now see why I have discussed relations which hitherto he may perhaps have thought very little connected with my subject. He sees that there is a bond of sympathy between our earth and the sun; that no disturbance can affect the solar photosphere without affecting our earth to a greater or less degree. But if our earth, then also the other[331] planets. Mercury and Venus, so much nearer the sun than we are, surely respond even more swiftly and more distinctly to the solar magnetic influences. But beyond our earth, and beyond the orbit of moonless Mars, the magnetic impulses speed with the velocity of light. The vast globe of Jupiter is thrilled from pole to pole as the magnetic wave rolls in upon it; then Saturn feels the shock, and then the vast[332] distances beyond which lie Uranus and Neptune are swept by the ever-lessening yet ever-widening disturbance wave. Who shall say what outer planets it then seeks? or who, looking back upon the course over which it has traveled, shall say that planets alone have felt its effects? Meteoric and cometic systems have been visited by the great magnetic wave, and upon the dispersed members of the one and the subtle structure of the other effects even more important may have been produced than those striking phenomena which characterize the progress of the terrestrial or planetary magnetic storms.

When we remember that what is true of a relatively great solar disturbance, such as the one witnessed by Messrs. Carrington and Hodgson, is true also (however different in degree) of the magnetic influences which the sun is at every instant exerting, we see that a new and most important bond of union exists between the members of the solar family. The sun not only sways them by the vast attraction of his gravity, not only illumines them, not only warms them, but he pours forth on all his subtle yet powerful magnetic influences. A new analogy between the members of the Solar System is thus introduced to reinforce those other analogies which have been held so strikingly to indicate that the ends for which our earth has been created are not different from those which the Creator had in view when He planned the other members of the Solar System.

The real end and aim of the telescope, as applied by the astronomer to the examination of the celestial objects, is to gather together the light which streams[333] from each luminous point throughout space. We may regard the space which surrounds us on every side as an ocean without bounds or limits, an ocean across which there are ever sweeping waves of light, either emitted directly from the various bodies subsisting throughout space, or else reflected from their surfaces. Other forms of waves also speed across those limitless depths in all directions, but the light-waves are those which at present concern us. Our earth is as a minute island placed within the ocean of space, and to the shores of this tiny isle the light-waves bear their message from the orbs which lie like other isles amid the fathomless depths around us. With the telescope the astronomer gathers together portions of

light-waves which else would have traveled in diverging directions. By thus intensifying their action, he enables the eye to become cognizant of their true nature. Precisely as the narrow channels around our shores cause the tidal wave, which sweeps across the open ocean in almost insensible undulations, to rise and fall through a wide range of variation, so the telescope renders sensible the existence of light-waves which would escape the notice of the unaided eye.

The telescope, then, is essentially a light-gatherer.

The spectroscope is used for another purpose. It might be called the light-sifter. It is applied by the astronomer to analyze the light which comes to him from beyond the ocean of space, and so to enable him to learn the character of the orbs from which that light proceeds.

The principle of the instrument is simple, though[334] the appliances by which its full powers can alone be deduced are somewhat complicated.

A ray of sunlight falling on a prism of glass or crystal does not emerge unchanged in character. Different portions of the ray are differently bent, so that when they emerge from the prism they no longer travel side by side as before. The violet part of the light is bent most, the red least; the various colors from violet through blue, green, and yellow, to red being bent gradually less and less.

The prism then sorts, or sifts, the light-waves.

But we want the means of sifting the light-waves more thoroughly. The reader must bear with me while I describe, as exactly as possible in the brief space available to me, the way in which the first rough work of the prism has been modified into the delicate and significant work of the spectroscope. It is well worth while to form clear views on this point, because so many of the wonders of modern science are associated with spectroscopic analysis.

If, through a small round hole in a shutter, light is admitted into a darkened room, and a prism be placed with its refracting angle downward and horizontal, a vertical spectrum, having its violet end uppermost, will be formed on a screen suitably placed to receive it.

But now let us consider what this spectrum really is. If we take the light-waves corresponding to any particular color, we know, from optical considerations, that these waves emerge from the prism in a pencil exactly resembling in shape the pencil of white light which falls on the prism. They therefore form[335] a small circular or oval image on their own proper part of the spectrum. Hence the spectrum is in reality formed of a multitude of overlapping images, varying in color from violet to red. It thus appears as a rainbow-tinted streak, presenting every gradation of color between the utmost limits of visibility at the violet and red extremities.

If we had a square aperture to admit the light, we should get a similar result. If the aperture were oblong, there would still be overlapping images; but if the length of the oblong were horizontal, then, since each image would also be a horizontally placed oblong, the overlapping would be less than when the images were square. Suppose we diminish the overlapping as much as possible? in other words, suppose we make the oblong slit as narrow as possible? Then, unless there were in reality an infinite number of images distributed all along the spectrum from top to bottom, the images might be so narrowed as not to overlap; in which case, of course, there would be horizontal dark spaces or gaps in our spectrum. Or, again, if we failed in finding gaps of this sort by simply narrowing the aperture, we might lengthen the spectrum by increasing the refracting angle of the prism, or by using several prisms, and so on.

The first great discovery in solar physics, by means of the analysis of the prism (though the discovery had little meaning at the time), consisted in the recognition of the fact that, by means of such devices as the above, dark gaps or cross-lines can be seen in the solar spectrum. In other words, light-waves of the various gradations corresponding[336] to all the tints of the spectrum from violet to red do not travel to us from the great central luminary of our system. Remembering that the effect we call color is due to the length of the light-waves, the effect of red corresponding to light-waves of the greatest length, while the effect of violet corresponds to the shortest light-waves, we see that in effect the sun sends forth to the worlds which circle around him light-waves of many different lengths, but not of all. Of so complex and interesting a nature is ordinary daylight.

But spectroscopists sought to interpret these dark lines in the solar spectrum, and it was in carrying out this inquiry—which even to themselves seemed almost hopeless, and to many would appear an utter waste of time—that they lighted upon the noblest method of research yet revealed to man.

They examined the spectra of the light from incandescent substances (white-hot metals and the like), and found that in these spectra there are no dark lines.

They examined the spectra of the light from the stars, and found that these spectra are crossed by dark lines resembling those in the solar spectrum, but differently arranged.

They tried the spectra of glowing vapors, and they obtained a perplexing result. Instead of a number of dark lines across a rainbow-tinted streak, they found bright lines of various colors. Some gases would give a few such lines, others many, some only one or two.

Then they tried the spectrum of the electric spark,[337] and they found here also a series of bright lines, but not always the same series. The spectrum varied according to the substances between which the spark was taken and the medium through which it passed.

Lastly, they found that the light from an incandescent solid or liquid, when shining through various vapors, no longer gives a spectrum without dark lines, but that the dark lines which then appear vary in position, according to the nature of the vapor through which the light has passed.

Here were a number of strange facts, seemingly too discordant and too perplexing to admit of being interpreted. Yet one discovery only was wanting to bring them all into unison.

In 1859, Kirchhoff, while engaged in observing the solar spectrum, lighted on the discovery that a certain double dark line, which had already been found to correspond exactly in position with the double bright line forming the spectrum of the glowing vapor of sodium, was intensified when the light of the sun was allowed to pass through that vapor. This at once suggested the idea that the presence of this dark line (or, rather, pair of dark lines) in the spectrum of the sun is due to the existence of the vapor of sodium in the solar atmosphere, and that this vapor has the power of absorbing the same order of light-waves as it emits. It would of course follow from this that the other dark lines in the solar spectrum are due to the presence of other absorbent vapors in its atmosphere, and that the identity of these would admit of being established in the same way, supposing this general law to hold,[338] that a vapor emits the same light-waves that it is capable of absorbing.

Kirchhoff was soon able to confirm his views by a variety of experiments. The general principles to which his researches led—in other words, the principles which form the basis of spectrum analysis—are as follows:

1. An incandescent solid or liquid gives a continuous spectrum.

2. A glowing vapor gives a spectrum of white lines, each vapor having its own set of bright lines, so that, from the appearance of a bright-line spectrum, one can tell the nature of the vapor or vapors whose light forms the spectrum.

3. An incandescent solid or liquid shining through absorbent vapors gives a rainbow-tinted spectrum crossed by dark lines, these dark lines having the same position as the bright lines belonging to the spectra of the vapors; so that, from the arrangement of the dark lines in such a spectrum, one can tell the nature of the vapor or vapors which surround the source of light.[24]

[339]

The application of the new method of research to the study of the solar spectrum quickly led to a number of most interesting discoveries. It was found that, besides sodium, the sun’s atmosphere contains the vapors of iron, calcium, magnesium, chromium, and other metals. The dark lines corresponding to these elements appear unmistakably in the solar spectrum. There are other metals, such as copper and zinc, which seem to exist in the sun, though some of the corresponding dark lines have not yet been recognized. As yet it has not been proved that gold, silver, mercury, tin, lead, arsenic, antimony, or aluminium exist in the sun—though we can by no means conclude, nor indeed is it at all probable, that they are absent from his substance. The dark lines belonging to hydrogen are very well marked indeed in solar spectrum, and, as we shall see presently, the study of these lines has afforded most interesting information respecting the physical constitution of the sun.

Now we notice at once how importantly these researches into the sun’s structure bear upon the subject[340] of this treatise. It would be indeed interesting to consider the actual condition of the central orb of the planetary scheme, to picture in imagination the metallic oceans which exist upon his surface, the continual evaporation from those oceans, the formation of metallic clouds, and the downpour of metallic showers upon the surface of the sun. But apart from such considerations, and viewing Kirchhoff’s discoveries

simply in their relation to the subject of other worlds, we have enough to occupy our attention.

If it could have been shown that, in all probability, the substance of the sun consists of materials wholly different from those which exist in this earth, the conclusion obviously to be drawn from such a discovery would be that the other planets also are differently constituted. We could not find any just reason for believing that in Jupiter or Mars there exist the elements with which we are acquainted, when we found that even the central orb of the planetary system exhibits no such feature of resemblance to the earth. But now that we know, quite certainly, that the familiar elements, iron, sodium, and calcium, exist in the sun's substance, while we are led to believe, with almost perfect assurance, that all the elements we are acquainted with also exist there, we see at once that, in all probability, the other planets are constituted in the same way. There may of course be special differences: in one planet the proportionate distribution of the elements may differ, and even differ very markedly, from that which prevails in some other planet. But the general conclusion[341] remains, that the planets are formed of the elements which have so long been known as terrestrial; for we can not recognize any reason for believing that our earth alone, of all the orbs which circle around the sun, resembles that great central orb in general constitution.

Now, we have in this general law a means of passing beyond the bounds of the Solar System, and forming no indistinct conceptions as to the existence and character of worlds circling around other suns. For these orbs, like our sun, contain in their substance many of the so-called terrestrial elements, while it may not unsafely be asserted that all, or nearly all, those elements, and few or no elements unknown to us, exist in the substance of every single star that shines upon us from the celestial concave. Hence we conclude that round those suns also there circle orbs constituted like themselves, and therefore containing the elements with which we are familiar. And the mind is immediately led to speculate on the uses which those elements are intended to subserve. If iron, for example, is present in some noble orb circling around Sirius, we speculate not unreasonably respecting the existence on that orb—either now or in the past, or at some future time—of beings capable of applying that metal to the useful purposes which man makes it subserve. The imagination suggests immediately the existence of arts and sciences, trades and manufactures, on that distant world. We know how intimately the use of iron has been associated with the progress of human civilization, and though we must ever remain in ignorance[342] of the actual condition of intelligent beings in other worlds, we are yet led, by the mere presence of an element which is so closely related to the wants of man, to believe, with a new confidence, that for such beings those worlds must in truth have been fashioned.

I would fain dwell longer on the thoughts suggested by the researches of Kirchhoff. Gladly too would I enter at length on an account of those interesting discoveries which have been made in connection with the total eclipses of the sun. One point, however, remains which is too intimately connected with my subject to be passed over.

I refer to the sun's corona.

It has been proved that the solar prominences consist of glowing vapors, hydrogen being their chief constituent. It has been found also, by comparing Mr. Lockyer's observations of the prominence-spectra with Dr. Frankland's elaborate researches into the peculiarities presented by the spectrum of hydrogen at different pressures, that even in the very neighborhood of the solar photosphere these vapors probably exist at a pressure so moderate as to indicate that the limits of the sun's vaporous envelope can not lie very far (relatively) from the outer solar cloud-layer.

Now, the solar corona has been seen, during total eclipses of the sun, to extend to a distance at least equal to the sun's diameter from the eclipsed orb. So that, assuming the corona to be a solar atmosphere, it would have a depth of about eight hundred and fifty thousand miles, and being also drawn toward[343] the sun by his enormous attractive energy (exceeding more than twenty-seven times that of the earth), it could not fail to exert a pressure on his surface exceeding many thousand-fold that of our air upon the earth. In fact, such an atmosphere, let its outermost layers be as rare as we can conceive, would yet have its lower layers absolutely liquefied, if not solidified, by the enormous pressure to which they would be subjected. We can not, then, believe this corona to be a solar atmosphere. Heavenly bodies Fig. 33.—Tychonic System

Yet it is quite impossible to dissociate the corona, either wholly or in part, from the sun. I am aware that physicists of eminence have attempted to do this, and not only so, but to make of the zodiacal light a terrestrial phenomenon. But they have overlooked considerations which oppose themselves irresistibly to such a conclusion.

In the first place, the mere fact that, during a total eclipse, the moon looks black, in the very heart[344] of the corona, affords, when properly understood, the most conclusive evidence that the light of the corona comes from behind the moon. If the glare of our atmosphere could by any possibility account for the corona (which is not the case), then that glare should appear over the moon's

disk also. That this is so is proved by the fact that, when the glare really does cover the moon, as while the sun is but slightly eclipsed, the moon is not projected as a black disk on the background of the sky, though, where her outline crosses the sun, it appears black, by contrast with the intensity of his light.[25] The point seems, however, too obvious to need discussion.

And, secondly, as Mr. Baxendell has pointed out, during totality the part of the earth's atmosphere between the eye and the corona is not illuminated by the sun. Over a wide space all round the sun we are looking through an atmosphere which is completely dark. In fact, if the earth's atmosphere alone were in question, we ought to see a dark or negative corona around the sun, the illuminated atmosphere only beginning to be faintly visible at a considerable angular distance from the sun. This argument, rightly understood, is altogether decisive of the question.[26]

[345]

But the spectroscope has given certain very perplexing evidence respecting the light of the corona, and it remains that we should endeavor to see how that evidence bears on the interesting problem which the corona presents to our consideration.

During the total eclipse of 1868 the American observers found that the spectrum of the corona is continuous, but crossed by certain bright lines. If we accept the absence of dark lines as established by the evidence (which is doubtful), this result seems at first sight very difficult to explain. Referring to the principles of spectroscopic analysis stated on pp. 338-339, it will be seen that we should be led to infer that the corona consists of incandescent matter surrounded by certain glowing gases. It is difficult to suppose that this is the real explanation of the phenomenon.

Mr. Lockyer suggests that, if the corona shone by[346] reflecting the solar light, the continuous spectrum might be accounted for by supposing the light from the glowing vapors around the sun to supply the part wanting where the solar dark lines are, and that some of these vapors shining yet more brightly would exhibit their bright lines upon the continuous background of the spectrum. This view, as applied by Mr. Lockyer to the theory that the corona is a terrestrial phenomenon, is untenable, for the reasons already adduced. But, independently of those reasons, there are others which render such a solution of the difficulty unavailable.

Now, remembering that we have two established facts for our guidance—(1) the fact that the corona can not be a solar atmosphere, and (2) the fact that it must be a solar appendage—I think a way may be found toward a satisfactory explanation.

Let it be premised that the bright lines of the coronal spectrum correspond in position to those seen in the spectrum of the aurora, and that the same lines are seen in the spectrum of the Zodiacal Light, and in that of the phosphorescent light occasionally seen over the heavens at night.

Since we have every reason to believe that the light of the aurora is due to electrical discharges taking place in the upper regions of the air, we are invited to the belief that the coronal light may be due to similar discharges taking place between the particles (of whatever nature) constituting the corona.

Now, though the appearance of an aurora is due to some special terrestrial action (however excited),[347] yet the material substances between which the discharges take place must be assumed to be at all times present in the upper regions of air. In all probability, they are the particles of those meteors which the earth is continually encountering. And since we know that meteor-systems must be aggregated in far greater numbers near the sun than near the earth, we may regard the coronal light as due to electrical discharges excited by the sun's action, and taking place between the members of such systems. Besides this light, however, there must necessarily be a large proportion of light reflected from these meteoric bodies. In this way the peculiar character of the coronal spectrum may be readily accounted for. We know, from the auroral spectrum, that the principal bright lines due to the electrical discharges would be precisely where we see bright lines in the coronal spectrum. But, besides these, there would be fainter bright lines corresponding to the various elements which exist in the meteoric masses. These elements, we know, are the same as those in the substance of the sun. Thus the bright lines would correspond in position with the dark lines of the solar spectrum. Hence, as light reflected by the meteors would give the ordinary solar spectrum, there would result from the combination a continuous spectrum, on which the bright lines first mentioned would be seen, as during the American eclipse.

What the polariscope has told us respecting the corona is in accordance with this view.

In the same way the quality of the Zodiacal Light[348] admits of being perfectly accounted for, without resorting to the hypothesis that this phenomenon is a terrestrial one.

The explanation thus put forward has at least the advantage of being founded on well-established relations. We know that the auroral light is associated with the earth's magnetism, and that meteoric bodies are continually falling upon the earth's atmosphere. We know, also, that the sun exerts magnetic influences a thousand-fold more intense than those of the earth, and that in his neighborhood there must be many million times more meteoric systems.

But we have other and independent reasons, which must not be overlooked, for considering the corona to be of some such nature as I have suggested. Leverrier has shown that there probably exists in the neighborhood of the sun a family of bodies whose united mass suffices appreciably to affect the motions of the planet Mercury. It would not be safe to neglect considerations thus vouched for.

Mr. Baxendell also has shown that certain periodic variations in the earth's magnetism point to the existence of such a family of bodies; and he has been able to assign to them a position according well with that determined by Leverrier.

Now, whatever opinion we form as to the exact character of the system of bodies pointed to by the researches of Leverrier and Baxendell—whether we suppose that system to form a zone around the sun, or that (as I believe) the system is merely due to the aggregation of meteoric perihelia in the sun's[349] neighborhood—we may be quite certain of this, that during a total solar eclipse the system could not fail to become visible. Hence there is a double objection to the view put forward by Mr. Lockyer and others. In the first place, it fails to account for the appearance presented by the corona; in the second place, it fails to render an account of the implied non-appearance of the system which, according to the researches of Leverrier and Baxendell, circles around the sun. Relative sizes Fig. 34.—Scale of Planets Jupiter and Saturn are shown in their true axial positions, Uranus and Neptune in the axial positions inferred from the motions of their satellites

We know that the sun is the sole source whence light and heat are plentifully supplied to the worlds which circle around him. The question immediately suggests itself—Whence does the sun derive[350] those amazing stores of force from whence he is continually supplying his dependent worlds? We know that, were the sun a mass of burning matter, he would be consumed in a few thousand years. We know that, were he simply a heated body, radiating light and heat continually into space, he would in like manner have exhausted all his energies in a few thousand years—a mere day in the history of his system. Whence, then, comes the enormous supply of force which he has afforded for millions on millions of years, and which also our reason tells us he will continue to afford while the worlds which circle around him have need of it—in other words, for countless ages to come?

Now, there are two ways in which the solar energies might be maintained. The mere contraction of the solar substance, Helmholtz tells us, would suffice to supply such enormous quantities of heat that, if the heat actually given out by the sun were due to this cause alone, there would not, in many thousands of years, be any perceptible diminution of the sun's diameter. But, secondly, the continual downfall of meteors upon the sun would cause an emission of heat in quantities vast enough for the wants of all the worlds circling round him; while his increase of mass from this cause would not be rendered perceptible in thousands of years, either by any change in his apparent size or by changes in the motions of his family of worlds.

It seems far from unlikely that both these processes are in operation at the same time. Certainly the latter is, for we know, from the motions of the[351] meteoric bodies which reach the earth, that myriads of these bodies must continually fall upon the sun. And if the corona and Zodiacal Light really be due to the existence of flights of meteoric systems circling around the sun, or to the existence in his neighborhood of the perihelia of many meteoric systems, then there must be a supply of light and heat from this source very nearly if not quite sufficient to account for the whole solar emission.

It is well worthy of notice, too, that the association between meteors and comets has an important bearing on this question. We know that the most remarkable characteristic of comets is the enormous diffusion of their substance. Now, in this diffusion there resides an enormous fund of force. The contraction of a large comet to dimensions corresponding to a very moderate mean density would be accompanied by the emission of a vast supply of heat. And the question is worth inquiring into, whether we can indeed assume that the meteors which reach our atmosphere are solid bodies, and not rather of cometic diffusion; since it is difficult otherwise to account for the light and heat which they emit. Friction through the rarer upper strata of our atmosphere will certainly not account for these phenomena; nor, I think, will the compression of the atmosphere in front of the meteors; on the other hand, the sudden contraction of a diffused vapor would be accompanied by precisely such results. But, be this as it may, it is certain that a large portion of the substance of every comet is in a singularly diffused state. And since the meteoric systems[352] circling in countless millions round the sun are, in all probability, associated in the most intimate manner with comets, we may recognize in this diffusion, as well as in the mere downfall of meteors, the source of an enormous supply of light and heat.

And lastly, turning from our sun to the other suns which shine in uncounted myriads throughout space, we see the same processes at work upon them all. Each star-sun has its coronal and its zodiacal disks, formed by meteoric and cometic systems; for otherwise each would quickly cease to be a sun. Each star-sun emits, no doubt, the same magnetic influences which give to the Zodiacal Light and to the solar corona their peculiar characteristics. And thus the worlds which circle round those orbs may resemble our own in all those relations which we refer to terrestrial magnetism, as well as in the circumstance that on them also there must be, as on our own earth, a continual downfall of minute meteors. In those worlds, perchance, the magnetic compass directs the traveler over desert wastes or trackless oceans; in their skies, the aurora displays its brilliant streamers; while, amid the constellations which deck their heavens, meteors sweep suddenly into view, and comets extend their vast length athwart the celestial vault, a terror to millions, but a subject of study and research to the thoughtful.

[353] FOOTNOTES:

[23] Professor Kirkwood has published a most interesting series of inquiries, going far to prove that the real secret or the planetary influences lies in the fact that the sun's surface is not uniform, and that on a certain solar longitude the planetary influences are more effective than elsewhere.

[24] To these may be added the following law:

4. Light reflected from any opaque body gives the same spectrum as it would have given before reflection.

5. But if the opaque body be surrounded by vapors, the dark lines corresponding to these vapors make their appearance in the spectrum with a distinctness proportioned to the extent to which the light has penetrated those vapors before being reflected to us.

6. If the reflecting body be itself luminous, the spectrum belonging to it is superadded to the spectrum belonging to the reflected light.

7. Glowing vapors surrounding an incandescent source of light may cause bright lines or dark lines to appear in the spectrum, according as they are more or less heated; or, they may emit just so much light as to make up for what they absorb, in which case there will remain no trace of their presence.

8. The electric spark presents a bright-line spectrum, compounded of the spectra belonging to the vapors of those substances between which, and of those through which, the discharge takes place. According to the nature of these vapors and of the discharge itself, the relative intensity of the component parts of the spectrum will be variable.

Lastly, the appearance of the spectrum belonging to any element will vary according to the circumstances of pressure and temperature under which the element may emit light.

[25] It is also shown most conclusively, by a photograph of the eclipse of August, 1868, taken an instant before the totality. Here we see the glare trenching upon the moon's disk (elsewhere black), as it should theoretically. So soon as totality commenced, the glare had reached the moon's limb, whence it must immediately have passed quickly away.

[26] In fact, if we take the mode of reasoning by which Mr. Lockyer has endeavored to get over certain physical difficulties presently to be mentioned, we shall be able to point definitely to the place where his argument fails. He says, conceive a tiny moon placed so as to appear coincident with the centre of the sun's disk. There will be atmospheric glare as well as direct sunlight. Now, conceive this small moon to expand until it all but covers the sun. Still there will be glare and a certain small proportion of direct sunlight. So far his reasoning is most just. But when he allows his expanding moon to cover the sun, and to extend beyond the solar disk as in total eclipse, the atmospheric glare can no longer be assumed to exist all round the expanding moon: at the moment when the moon just hides the sun, the glare begins to leave the moon, a gradually expanding black ring being formed round that body. It is only necessary to consider where the glare comes from to see that this must be so.

I have taken no account of diffraction here, because it has been abundantly proved that no corona of appreciable width could be formed around the moon during total eclipse by the diffraction of the rays of light as they pass near the moon's limb.
MERCURY.—William F. Denning

Mercury is the nearest known planet to the sun. It is true that a body, provisionally named Vulcan, has been presumed to exist in the space inferior to the orbit of Mercury; but absolute proof is lacking, and every year the idea is losing strength in the absence of any confirmation of a reliable kind. Not one of the regular and best observers of the sun has recently detected any such body during

its transits (which would be likely to occur pretty frequently), and there is other evidence of a negative character; so that the ghost of Vulcan may be said to have been laid, and we may regard it as proven that no major planet revolves in the interval of 36,000,000 miles separating Mercury from the sun.

Copernicus, amid the fogs of the Vistula, looked for Mercury in vain, and complained in his last hours that he had never seen it. Tycho Brahe, in the Island of Hueen, appears to have been far more successful. The planet is extremely fugitive in his appearances, but is not nearly so difficult to find as many suppose. Whenever the horizon is very clear, and the planet well placed, a small sparkling object, looking more like a scintillating star than a planetary body, will be detected at a low altitude and may be followed to the horizon.

Mercury revolves round the sun in 87 days, 23 hours, 15 minutes, and 44 seconds in an eccentric orbit, so that his distance from that luminary varies[354] from 43,350,000 to 28,570,000 miles. When in superior conjunction the apparent diameter of the planet is 4″.5; at inferior conjunction it is 12″.9, and at elongation 7″. His real diameter is 3,000 miles.

Being situated so near to the sun, it is obvious that to an observer on the earth he must always remain in the same general region of the firmament as that body. His orbital motion enables him to successively assume positions to the east and west of the sun, and these are known as his elongations, which vary in distance from 18° to 28°. He becomes visible at these periods either in the morning or evening twilight, and under the best circumstances may remain above the horizon two hours in the absence of the sun. The best times to observe the planet are at his E. elongations during the first half of the year, or at his W. elongations in the last half; for his position at such times being N. of the sun's place, he remains a long while in view.

Occasionally he presents quite a conspicuous aspect on the horizon, as in February, 1868, when I thought his lustre vied with that of Jupiter, and in November, 1882, when he shone brighter than Sirius. The planet is generally most conspicuous a few mornings after his W. elongations and a few evenings before his E. elongations.

In the course of his orbital round, Mercury exhibits all the phases of the moon. Near his elongations the disk is about half illuminated, and similar in form to that of our satellite when in the first or third quarter. But the phase is not to be distinctly made out unless circumstances are propitious. Galileo's[355] telescope failed to reveal it, and Hevelius, many years afterward, found it difficult. This is explained by the small diameter of the planet and the rarity with which his disk appears sharply defined. The phase is sometimes noted to be less than theory indicates; for the planet has been seen crescented when he should have presented the form of a semicircle. Several observers have also remarked that his surface displays a rosy tint, and that the terminator is more deeply shaded and indefinite than that of Venus.

The atmosphere of Mercury is probably far less dense than that of Venus. The latter being furthest from the sun might be expected to shine relatively more faintly than the former, but the reverse is the case. Mercury has a dingy aspect in comparison with the bright white lustre of Venus. On May 12, 1890, when the two planets were visible as evening stars, and separated from each other by a distance of only 2°, I examined them in a 10-inch reflector, power 145. The disk of Venus looked like newly polished silver, while that of Mercury appeared of a dull leaden hue. A similar observation was made by Mr. Nasmyth on September 28, 1878. The explanation appears to be that the atmosphere of Mercury is of great rarity, and incapable of reflection in the same high degree as the dense atmosphere of Venus.

As a naked-eye object, Mercury must necessarily be looked for when near the horizon; but there is no such need in regard to telescopic observation, which ought to be only attempted when the planet[356] surmounts the dense lower vapors and is placed at a sufficient elevation to give the instrument a fair chance of producing a steady image. The presence of sunshine need not seriously impair the definition, or make the disk too faint for detail.

I have occasionally seen Mercury, about two or three hours after his rising, with outlines of extreme sharpness and quite comparable with the excellent views obtained of Venus at the time of sunrise or sunset. Those who possess equatorials should pick up the planet in the afternoon and follow him until after sunset, when the horizontal vapors will interfere. Others who work with ordinary altazimuth stands will find it best to examine the planet at his western elongations during the last half of the year, when he may be found soon after rising by the naked eye or with an opera-glass, and retained in the telescope for several hours after sunrise if necessary.

Mercury was displayed under several advantages in the morning twilight of November, 1882, and I made a series of observations with a 10-inch reflector, power 212. Several dark markings were perceived, and a conspicuous white spot. The general appearance

of the disk was similar to that of Mars, and I forwarded a summary of my results to Professor Schiaparelli of Milan, who favored me with the following interesting reply:

“I have myself been occupied with this planet during the past year (1882). You are right in saying that Mercury is much easier to observe than Venus, and that his aspect resembles Mars more than any other of the planets of the Solar System. It has[357] some spots which become partially obscured and sometimes completely so; it has also some brilliant white spots in a variable position.”

Professor Schiaparelli used an 8½-inch refractor in this work, and was able under some favorable conditions to apply a power of 400. The outcome of his researches, encouraged since 1882 by the addition of an 18-inch refractor to the appliances of his observatory, was announced in the curious fact that the rotation of Mercury is performed in the same time that the planet revolves round the sun! If this conclusion is just, Mercury constantly presents one and the same hemisphere to the sun, and the behavior of the moon relatively to the earth has found an analogy.

Spots or markings of any kind have rarely been distinguished on Mercury. On June 11, 1867, Prince recorded a bright spot, with faint lines diverging from it northeast and south. The spot was a little south of the centre. Birmingham on March 13, 1870, glimpsed a large white spot near the planet’s east limb, and Vögel, at Bothkamp, observed spots on April 14 and 22, 1871. These instances are quoted by Webb, and they, in combination with the markings seen by Schiaparelli at Milan and by the author at Bristol in 1882, sufficiently attest that this object deserves more attentive study.

One of the most interesting phenomena, albeit a somewhat rare event, in connection with Mercury, is that of a transit across the sun. The planet then appears as a black circular spot. Observers have noticed one or two very small luminous points on the[358] black disk, and an annulus has been visible round it. These features are probably optical effects. THE PLANET VENUS.—Camille Flammarion

Revolving round the sun in 224 days, Venus has its motion combined with ours in such a manner that it passes its inferior conjunction, between the sun and us, every 584 days; but the plane in which it revolves is inclined 3° 23′ to that in which the earth itself moves. When Venus attains its greatest elongations from the sun it shines in the west in the evening, then in the morning in the east, with a splendid brightness which eclipses that of all the stars. It is, without comparison, the most magnificent star of our sky. Its light is so vivid that it casts a shadow. Sometimes, even, it pierces the azure of the sky, in spite of the presence of the sun above the horizon, and shines in full daylight.

The maximum visibility of Venus is produced by its greatest phase, by its greatest elongation from the sun, and by the clearness of our atmosphere.

The brilliant Venus was certainly the first planet noticed by the ancients, as much on account of its brightness as its rapid motion. Hardly is the sun set than it sparkles in the twilight; from evening to evening it removes further from the west and increases in brightness; during several months it reigns sovereign of the skies, then plunges into the solar fires and disappears. It was pre-eminently the star of the evening, the shepherd’s star, the star of sweet[359] confidences. It was the first of celestial beauties, and the names conferred upon it correspond to the direct impression which it produced on contemplative minds. Homer called it “Callistos,” the Beautiful; Cicero named it Vesper, the evening star, and Lucifer, the morning star, a name likewise given in the Bible and the ancient mythologies to the chief of the celestial army.

The most ancient astronomical observation we have of Venus is a Babylonian record of the year 685 B. C. It is written on a brick and preserved in the British Museum.

The best hours for examining Venus in a telescope are those of daylight. In the night the irradiation produced by the brilliant light of this beautiful planet prevents us from distinguishing clearly the outlines of its phases.

When Venus occupies the region of its orbit behind the sun, with reference to us—which is called the point of superior conjunction—it is at its greatest distance, and is reduced to a disk of 9½ seconds in diameter. It comes imperceptibly toward us, and when it passes its quadrature, at its mean distance, it presents the aspect of a half-moon. It soon attains its most brilliant light, at the epoch when it shines at a distance of 39° from the sun, and shows the third phase 69 days before its inferior conjunction. Its apparent diameter is then 40 seconds, and the width of its illuminated part is scarcely 10 seconds. In this position we see the fourth of the disk illuminated; but this quarter emits more light than the more complete phases. Finally, when it reaches[360] the region of its orbit nearest to the earth, it shows us nothing more than an excessively thin crescent, since it is then between the sun and us, and presents to us, so to say, its dark hemisphere. This is the position where its apparent size is greatest, and it then measures 62

seconds in diameter. After passing its inferior conjunction the phases are reproduced, in inverse order, as a morning star.

Venus is constantly visible in full daylight in astronomical instruments, even at the moment of its superior conjunction. It is then round and quite small. At the epochs of its inferior conjunction it presents itself under the form of a very thin crescent.

We sometimes notice that the interior of the crescent of Venus, the remainder of the disk, is less black than the background of the sky. This has been called the ashy light (lumière cendrée) of Venus, although it has no satellite to produce it. It seems to me that this visibility, rather subjective than objective, arises from clouds on the planet, which whiten its disk and vaguely reflect the stellar light scattered through space. The eye instinctively continues the outline of the crescent, and imagines, rather than sees, the rest.

The revolution of Venus round the sun is performed in an orbit almost exactly circular, and without perceptible eccentricity (0.0068), in a period of 224 days, 16 hours, 49 minutes, 8 seconds.

The days of Venus, also, are a little more rapid than ours, but not much. Since the year 1666 attentive observation of the planet led Cassini to conclude that it turns on itself in 23 hours, 15 minutes.[361] This observation is extremely difficult, on account of the brightness of the planet and the faintness of the irregularities visible on its disk.

The year of Venus, composed of 224 terrestrial days, consequently contains 231 of its own, since the day is a little shorter there than here.

These same observations show that the axis of rotation of this planet is much more inclined than ours, and that this inclination is 55 degrees. It follows that the seasons, although each lasting but 56 terrestrial days, or 58 Venusian days, are much more intense on this world than on ours. They pass, without transition, from summer to winter.

The inclination of the world of Venus being more than twice as great as ours, we have only to take a terrestrial globe and incline it by the same quantity to understand the climates and seasons which will result. We may easily see that the torrid zone extends, in this case, up to the frigid zone, and even beyond it; and, reciprocally, the frigid zone extends to the torrid zone, and even encroaches on it; so that no place remains for a temperate zone. There is not, then, on Venus any temperate climate, but all latitudes are both tropical and arctic.

It follows, then, from all these circumstances, that the seasons and climates are much more violent and more varied than ours. This neighboring world shows nearly the same dimensions as ours. Thus this planet is truly the twin sister of ours.

The resemblance will be still more complete if we add that this world is certainly surrounded by an atmosphere.

[362]

When we examine with the spectroscope the light reflected by this planet we first find the lines of the solar spectrum (and this is natural, since the planets have no light of their own, and merely reflect that of the sun); but we notice besides several absorption lines similar to those which the terrestrial atmosphere gives, and particularly those of clouds and water vapor.

We may also add that attentive observation of the indentations visible on the crescent of Venus has shown that the surface of this planet is quite as uneven as that of the earth, and even more so; that there are there Andes, Cordilleras, Alps, and Pyrenees, and that the most elevated summits attain a height of 44,000 metres (27 miles). It has even been ascertained that the Northern Hemisphere is more mountainous than the Southern.

Even the study of the geography of Venus has already been commenced. But it is extremely difficult to draw, and the hours of sufficiently pure atmosphere and possible observation are very rare. This difficulty will be easily understood if we reflect that it is exactly when Venus arrives at its nearest to us that it is least visible, since, its illuminated hemisphere being always turned toward the sun, it is its dark hemisphere which is presented to us. The nearer it approaches us, the narrower the crescent becomes. Add to this its vivid light and its clouds, and you may imagine what difficulty astronomers have in dealing with it. Drawings of Jupiter Twelve Views of Jupiter Taken at Intervals within Six Consecutive Weeks

However, by observing it in the daytime to avoid the glare, and not waiting till the crescent becomes[363] too thin, by choosing the quadratures, and making use of moments of great atmospherical purity, observers succeed, from time to time, in perceiving grayish spots, which may indicate the place of its seas.

Of what nature are the inhabitants of Venus? Do they resemble us in physical form? Are they endowed with an intelligence analogous to ours? Do they pass their life in pleasure, as Bernardin de St. Pierre said, or, rather, are they so tormented by the inclemency of their seasons that they have no delicate perception, and are incapable of any scientific or artistic attention? These are interesting questions, to which we have no reply. All that we can say is, that organized life on Venus must be little different from terrestrial life, and that this world is one of those which resembles ours most. The imaginary travelers to these worlds of the sky have always carried with them their terrestrial ideas. The only scientific conclusion which we can draw from astronomical observation is that this world differs little from ours in volume, in weight, in density, and in the duration of its days and nights; that it differs a little more in the rapidity of its years, the intensity of its climates and seasons, the extent of its atmosphere, and its greater proximity to the sun. It should, then, be inhabited by vegetable, animal, and human races but little different from those which people our planet. As to imagining it desert or sterile, this is a hypothesis which could not arise in the brain of any naturalist. The action of the divine sun must be there, as in Mercury, still more fertile than his terrestrial[364] work, already so wonderful. We may add that Venus and Mercury, having been formed after the earth, are relatively younger than our planet.

The inhabitants of Venus see us shining in their sky like a magnificent star of the first magnitude, soaring in the zodiac, and showing motions similar to those which the planet Mars presents to us; but instead of showing a reddish brightness, the earth shines in the sky as a bluish light. It is from Venus that we are most luminous. The inhabitants of Venus with the naked eye see our moon shining beside the earth and revolving round it in twenty-seven days. They form a magnificent couple. Our planet seen from there measures 65″, and the moon nearly 18″; the moon seen from Venus shows the same diameter as the earth seen from the sun. Mercury is brilliant, and comes immediately after the earth in brightness. Mars, Jupiter, and Saturn are also visible as from here, but a little less luminous. The constellations of the whole sky show exactly the same aspect as seen from the earth. THE EARTH AS A PLANET.—Élisée Reclus

The earth on which we dwell is one of the lowest in rank among the heavenly bodies. If an astronomer in some other planet were exploring the immensity of space, our earth, owing to its small size, might readily elude his intelligent view. A mere satellite of the sun, the volume of which is 1,255,000 times greater, the earth is but a point as[365] compared with the immense tract of ether traversed by the planets in their courses round their central globe. The sun itself is only a spark, which seems lost amid the eighteen millions of stars which Herschel's telescope discerned in the Milky Way; the latter, an immense agglomeration of suns and planets, which looks to us like a broad streak of light round the whole universe, is in reality nothing but a nebula. Beyond our own sky, other skies stretch far away into infinity, and others beyond these, so that light notwithstanding its prodigious rapidity, takes eternities to cross them. How small the earth seems in this fathomless abyss of stars!

In the form of its orbit, in its movements round the sun and on its own axis, in the succession of days and seasons, and in all the phenomena governed by the great law of attraction, the earth becomes the representative of all the other planets; in studying it, we study all the heavenly bodies.

Our planet is a spheroid; that is, a sphere flattened at the two poles and enlarged at the equator, so that all the circles passing through the extremity of the polar axis form ellipses. The presumed depression of each pole is about thirteen miles, nearly a three-hundredth part of the radius of the earth; but it is not altogether certain that the two poles are equally flattened. Perhaps a contrast exists between the two hemispheres, not only in the features of their continents and the distribution of seas, but also in their geometrical shape. Be this as it may, it appears to be proved that the curvature is not exactly the same at all points of the earth at an equal distance[366] from the poles; the meridians appear without exception to be irregular ellipses.

The dimensions of the earth, as we have already seen, are almost as nothing compared with the larger celestial bodies, and especially with the extent of space which can be explored by the telescope. If light, the speed of which has been adopted in astronomy as a term of comparison, could be diffused in a curved line, it would travel seven times round the globe in a second of time; this standard of measurement, therefore, the only one suited to the stellary field, is completely inapplicable to the surface of our globe.

The isolated globule in the immensity of space which we call the earth is not motionless, as the ancients necessarily supposed, looking upon it, as they did, as the immovable base of the firmament of heaven. Hurried on in the vortex of universal vitality, our globe is ever actuated by ceaseless motion, describing in ether a series of elliptic spirals so complicated that astronomers have not yet been able to calculate their various curves. Besides rotating on its own axis, the earth describes an ellipse round the sun, and, under the influence of this body, is drawn along from one heaven to another toward distant constellations. It also oscillates and rocks on its axis, and deviates more or less from its path, to salute, as it were, every heavenly body which meets it. It is probable

that it never passes a second time through the same regions of the air; yet, if it has again to traverse the spiral line of ellipses it has already described, it would be after a cycle of so many thousands[367] of millions of years, that the earth itself, completely transformed, would be no longer the same planet.

The motion of the earth, the immediate effects of which are the most obvious to the notice of men, is the daily rotation which takes place round an ideal axis passing through the two poles. The globe turns from right to left, or from west to east—that is, in a contrary direction to the apparent motion of the sun and stars, which seem to rise in the east and to set in the west. As the earth's axis terminates at each pole, there is least surface-motion at those points, and the motion is the more rapid in any part of the surface of the globe the further it is from the central axis. At St. Petersburg, in 60° latitude, the speed of rotation is about nine miles a minute; in Paris, it exceeds eleven and a half miles during the same brief time; on the equatorial line, which may be looked upon as the ring of an immense wheel, the speed of the earth is twice as great as it is at 60° of latitude—that is, about eighteen miles a minute, or 528 yards a second—a rapidity equal to the flight of a 26-pound cannon-ball impelled by thirteen pounds of powder. By means of this rotatory motion, the earth presents toward the sun each of its faces alternately, and each also in turn toward the comparatively darker regions of space; the succession of day and night is thus constituted. In addition to this, the rotation of the earth is an important fact which must always be taken into account in determining the direction of fluids in motion on the surface of the globe, such as streams and rivers, also marine and atmospheric currents.

[368]

The annual revolution which the earth performs round the sun follows the line of an ellipse, one of the foci of which is occupied by the central star; the eccentricity of the ellipse is nearly equal to 17/1000th of the great axis. The distance between the sun and the earth always varies according to the particular point of its orbit which the latter is traveling over. At its aphelion, that is, at its greatest remoteness, this distance is about 93¾ millions of miles; at the period of its perihelion, when the two heavenly bodies are nearest to each other, it is approximately 90,259,000 miles. The mean distance, as estimated by astronomers since the corrections of Encke, Hansen, Foucault, and Hind, is 91,839,000 miles. This extent of space is traversed by the solar rays in 8 minutes, 16 seconds; sound would take fifteen years in passing through the same distance.

As Kepler has laid down in his celebrated laws, our planet moves with an increased rapidity as it approaches nearer to the sun and travels more slowly in proportion to its distance from that luminary; but its mean speed may be estimated at nearly nineteen miles a second, or sixty times the rapidity of a ball from the cannon's mouth. This speed, which makes one dizzy to think of, is to be added, as regards each point in the surface of the earth, to the rotatory motion which impels it round the polar axis.

After having turned round 366 times on its axis, our planet has terminated its orbicular course, and is in the same position relatively to the sun as at its starting-point; it has then accomplished its year.

This daily rotation of the earth round its axis[369] produces the succession of days and nights, and, in the same way, its annual revolution round the sun causes the alternations of the seasons. If the axis of the earth, that is the ideal line which passes through its two poles, were perpendicular to the plane of its annual orbit, it is evident that the portion of the globe lighted by the sun would invariably extend from one pole to the other, and that in both hemispheres the days and nights would always consist of twelve hours each. But this is not the case. The earth performs its revolutionary movements in an inclined position; its ideal polar axis is sloped about 23° 28′ from a perpendicular to its plane, and this position is so far maintained that as regards the comparatively rapid succession of days and seasons it may be looked upon as invariable. This obliquity of axis causes continued changes in the phase presented to the sun. The portion of the earth illumined by the rays of the sun varies every day; for, although the planetary axis may appear to maintain its extremity in a fixed position as regards some point in infinite space, in respect to the sun it presents a constantly varying degree of inclination, in consequence of the continual motion of the earth. Twice during the course of the year it so happens that the solar rays fall perpendicularly upon the equator of the earth; at every other period in the annual revolution, sometimes the Northern and sometimes the Southern Hemisphere receives the greatest amount of light.

The astronomical year commences on the 20th of March, at the exact moment when the sun illumines the equator in a vertical direction, and the line of[370] separation between light and shade passes through the two poles. The period of darkness is then equal to that of light, and admits of exactly twelve hours at all points of the earth. Hence the name of "equinox" (equality of nights). But after this day, which in the Northern Hemisphere serves as the starting-point of spring, the earth continues its translatory movement. In consequence of the inclination of its axis, the Northern Hemisphere, being turned toward the sun, receives a greater quantity of light, while the southern half of the globe is less vividly lighted. The vertical rays of the sun now fall more and more to the

north of the equator, and the circle of light, far from arresting its progress at the poles, where the day of six months' duration is commencing to dawn, extends far beyond it over the regions of the north. On the 21st of June, the day of the first solstice, the axis of the earth being deeply inclined toward the sun, this luminary shines on the zenith of the tropic of Cancer at 23½° north of the equator, and its light illumines the whole of the arctic zone, that is, the portion of the earth's surface extending to 23½° round the North Pole. Then spring ceases and summer begins as regards the Northern Hemisphere. In the Southern Hemisphere, on the contrary, autumn is giving place to winter. Above the equator long days are prevailing, interrupted by short nights; while in the south it is the nights which last the longest. In the arctic zone the sun performs its apparent course of diurnal rotation entirely above the horizon. The six months' day, which spring inaugurated at the North Pole, attains its high noon[371] on the first day of summer. At the same moment midnight arrives in the darkness which is oppressing its antipodes.

Immediately after the 21st of June all the phenomena which took place during the preceding season are directly reversed. The sun appears to retrograde toward the southern horizon; its vertical rays cease to fall on the line of the northern tropic, and constantly approach the equator. The zone of light in the northern pole and of shade in the southern equally diminish, and the days shorten in the Northern Hemisphere in the same proportion as they lengthen in the Southern; an equilibrium is gradually being re-established between the two halves of the earth. On the 22d of September the position of the sun is again exactly above the equator, and its light just reaches both poles. The equinox, or the absolute equality of day and night in every part of the globe, occurs for the second time in the year; but this moment of equilibrium is, so to speak, but a mathematical point between the two seasons. The axis of the earth which, during the six months past, turned the North Pole toward the sun, now presents to him the South Pole; the vertical rays of the central luminary fall to the south of the earth's equator, and the Southern Hemisphere, in its turn, is the best endowed of the two halves of the globe in the amount of light it receives and in the length of its days. In the Southern Hemisphere spring is commencing; in the Northern, autumn. Three months afterward, on the 21st of December, the sun comes directly over the southern tropic, or the tropic[372] of Capricorn, 23½° south of the equator, and the whole of the antarctic zone is presented to the solar rays. Summer has begun in the Southern Hemisphere, and at the same time winter commences in that of the north. Then, as the globe moves on, these two seasons follow each other in their course, until at length the earth attains a position similar to that from which it started; the March equinox, the first day of spring in Europe, and the first day of autumn in Australia, commences anew the astronomical year.

The elliptical form of the earth's orbit and the unequal pace of the globe in the various points of its course cause some considerable variations in the duration of the seasons. In fact, from the 20th of March to the 22d of September, that is, during the spring and summer of the Northern Hemisphere, the earth takes 186 days to travel over the first and largest half of its orbit, while during the winter period, from the 22d of September to the 20th of March, only 179 days are required to accomplish the second half of its journey. The summer period of the Northern Hemisphere actually exceeds by seven or eight days, or about 187 hours, the corresponding period in the southern half of the globe; added to this, in consequence of the longer space of time during which the Arctic Pole remains inclined toward the sun in the regions north of the equator, the hours of daylight exceed the hours of night, while in the south the hours of darkness predominate. This is, however, to some extent compensated for; as, although in the southern regions of the earth the summer lasts a shorter time, our planet is then closer[373] to the sun; it is at its perihelion, and consequently receives a larger proportion of heat. There is, however, no doubt about the fact—as it is proved by a direct observation, both of the winds and currents, and also of their various temperatures—that, taking an equal distance from the equator, the southern regions are colder than those of the north.

If an equality of seasons between the two halves of the world does not at present exist, it will not fail to be established after a long series of centuries by means of a slow terrestrial movement, which has been known by the name of the precession of the equinoxes. Just as a top (if we may be allowed to avail ourselves of so old an illustration) turns round on the ground and bends over successively in every direction, thus describing with its axis an ideal cone, so the earth revolves in space, and slowly sways the line of its poles. This line, which is always sloped at an angle of 66° 32′ to the plane of the terrestrial orbit, turns round with a slight lateral motion, so as always to point to a new region of the sky; if it were prolonged indefinitely it would describe a circle amid the distant stars. As the axis of the earth is constantly changing its direction in this way, the plane of the equator must vary exactly to the same extent in its position as regards the sun. In fact, every year the exact moment of the March equinox anticipates by about twenty minutes the time at which the corresponding equinox fell in the year preceding. Each revolution of the earth round the sun brings a fresh advance of twenty minutes in the determination of the equinox; and as, during the long[374] course of ages, the axis of the earth does not intermit in this swaying motion, the time must come, after a period of 12,900 years, that the conditions of the seasons will be altogether changed. The hemisphere which hitherto received the larger proportion of heat will receive the lesser share, and that half of the globe which has endured the larger number of wintry days will now, in its turn, enjoy the more lengthened

period of summer. Then, after a second period of 12,900 years, during which the relation between the seasons of the two hemispheres is being gradually modified, the axis of the earth completes its round of swaying, which has lasted for 258 centuries, and the position of the globe in respect to the sun being nearly the same as at its starting-point, a second cycle of seasons will then commence.

We might call this period the earth's great year, if, at the end of it, the earth were in an identical position to that which it occupied at the commencement; but this is not the case. The attraction of the moon, and the disturbances caused by the vicinity of certain planets, are incessantly modifying the curve described in the starry fields of space by the earth's axis, and complicate it with a multitude of spirals, the various periods of which do not coincide with the great period of the swaying of the axis. The successive undulations form a continuous system of interwoven spirals. "It is a manifestation of the infinite."

But even this is not all. In addition to all the motions of the globe which we have already pointed out—its diurnal rotation, its annual revolution round[375] the sun, the rhythmical swaying of its axis, proved by the precession of the equinoxes, the nutation or more rapid swaying which is caused by the attraction of the moon—we must now notice the enormous translatory movement which is dragging it through endless tracks of space in the train of the sun. Not many years ago, this motion was entirely unknown to astronomers, and yet it is going on with inconceivable rapidity—a rapidity more than double that of the course of the planet round its central luminary. In one second of time the earth moves about forty-four miles toward the point of the heavens where we find the constellation of Hercules. During one year only she travels 1,382 millions of miles in this direction. Our own little earth itself is carried on from space to space, and never closes the cycle of its revolutions. Ever since the time when its particles were first grouped together, it has been describing in space the infinite spiral of its ellipses, and thus will it go on turning and oscillating in ether until the moment when it will exist no longer as an independent planet. For the earth, too, must have an end; like every other body in the universe, it comes into existence, and lives only to die when its turn comes. Already its annual motion of rotation is diminishing in speed; certainly this slackening of pace is not very observable, since no astronomer from Hipparchus to Laplace has yet exactly defined it. But, unless some cosmical force acting in a contrary direction compensates for the loss of speed caused by the friction of the tides against the bed and the shores of the ocean, the impetus of[376] our planet will every century diminish. After various catastrophes which it is impossible to foresee, the earth will eventually completely change its course of action, and lose its independent existence, either uniting itself with other planetary bodies or breaking up into fragments; or it will perhaps terminate its course by falling like a mere aerolite upon the surface of the sun. THE MOON.—Thomas Gwyn Elger

We know, both by tradition and published records, that from the earliest times the faint gray and light spots which diversify the face of our satellite excited the wonder and stimulated the curiosity of mankind, giving rise to superstitions more or less crude and erroneous as to their actual nature and significance. It is true that Anaxagoras, five centuries before our era, and probably other philosophers preceding him—certainly Plutarch at a much later date—taught that these delicate markings and differences of tint, obvious to every one with normal vision, point to the existence of hills and valleys on her surface; the latter maintaining that the irregularities of outline presented by the "terminator," or line of demarcation between the illumined and unillumined portion of her spherical superficies, are due to mountains and their shadows; but more than fifteen centuries elapsed before the truth of this sagacious conjecture was unquestionably demonstrated. Selenography, as a branch of observational astronomy, dates from the spring of 1609, when[377] Galileo directed his "optic tube" to the moon, and in the following year, in the Sidereus Nuncius, or the "Intelligencer of the Stars," gave to an astonished and incredulous world an account of the unsuspected marvels it revealed.

The bright and dusky areas, so obvious to the unaided sight, were found by Galileo to be due to a very manifest difference in the character of the lunar surface, a large portion of the Northern Hemisphere, and no inconsiderable part of the southeastern quadrant, being seen to consist of large gray monotonous tracts, often bordered by lofty mountains, while the remainder of the superficies was much more conspicuously brilliant, and, moreover, included by far the greater number of those curious ring-mountains and other extraordinary features whose remarkable aspect and peculiar arrangement first attracted his attention.

Before the close of the century when selenography first became possible, Hevel of Dantzig, Scheiner, Langrenus (cosmographer to the King of Spain), Riccioli, the Jesuit astronomer of Bologna, and Dominic Cassini, the celebrated French astronomer, greatly extended the knowledge of the moon's surface, and published drawings of various phases and charts, which, though very rude and incomplete, were a clear advance upon what Galileo, with his inferior optical means, had been able to accomplish. Langrenus, and after him Hevel, gave distinctive names to the various formations, mainly derived from terrestrial physical features, for which Riccioli subsequently substituted those of philosophers,[378] mathematicians, and other celebrities; and Cassini determined by actual measurement the relative position of many of the principal objects on the disk, thus laying the foundation of an accurate system of lunar topography; while the labors of T. Mayer and Schröter in the Eighteenth Century, and of Lohrmann, Mädler, Neison (Nevill),

Schmidt, and other observers in the Nineteenth, have been mainly devoted to the study of the minuter detail of the moon and its physical characteristics.

As was manifest to the earliest telescopic observers, its visible surface is clearly divisible into strongly contrasted areas, differing both in color and structural character. Somewhat less than half of what we see of it consists of comparatively level dark tracts, some of them many thousands of square miles in extent, the monotony of whose dusky superficies is often unrelieved for great distances by any prominent object; while the remainder, everywhere manifestly brighter, is not only more rugged and uneven, but is covered to a much greater extent with numbers of quasi-circular formations differing widely in size, classed as walled-plains, ring-plains, craters, craterlets, crater-cones, etc. (the latter bearing a great outward resemblance to some terrestrial volcanoes), and mountain ranges of vast proportions, isolated hills and other features.

Though nothing resembling sheets of water, either of small or large extent, has ever been detected on the surface of the moon, the superficial resemblance, in small telescopes, of the large gray tracts to the appearance which we may suppose our terrestrial[379] lakes and oceans would present to an observer on the moon, naturally induced the early selenographers to term them Maria, or "seas"—a convenient name, which is still maintained, without, however, implying that these areas, as we now see them, are, or ever were, covered with water.

There are twenty-three of these dusky areas which have received distinctive names; seventeen of them are wholly, or in great part, confined to the northern and to the southeastern quarter of the Southern Hemisphere—the southwestern quadrant being to a great extent devoid of them. By far the largest is the vast Oceanus Procellarum, extending from a high northern latitude to beyond latitude 10° in the southeastern quadrant, and, according to Schmidt, with its bays and inflections, occupying an area of nearly two million square miles, or more than that of all the remaining Maria put together. Next in order of size come the Mare Nubium, or about one-fifth the superficies, covering a large portion of the southeastern quadrant, and extending considerably north of the equator, and the Mare Imbrium, wholly confined to the northeastern quadrant, and including an area of about 340,000 square miles. These are by far the largest lunar "seas". The Mare Fœcunditatis, in the Western Hemisphere, the greater part of it lying in the southwestern quadrant, is scarcely half so big as the Mare Imbrium; while the Maria Serenitatis and Tranquilitatis, about equal in area (the former situated wholly north of the equator and the latter only partially extending south of it), are still smaller. The arctic Mare Frigoris, some[380] 100,000 square miles in extent, is the only remaining large sea; the rest, such as the Mare Vaporum, the Sinus Medii, the Mare Crisium, the Mare Humorum, and the Mare Humboldtianum, are of comparatively small dimensions, the Mare Crisium not greatly exceeding 70,000 square miles, the Mare Humorum (about the size of England) 50,000 square miles, while the Mare Humboldtianum, according to Schmidt, includes only about 42,000 square miles, an area which is approached by some formations not classed with the Maria.

Among the Maria which exhibit the most remarkable arrangement of ridges is the Mare Humorum, in the southeastern quadrant. Here, if it be observed under a rising sun, a number of these objects will be seen extending from the region north of the ring-mountain Vitello in long undulating lines, roughly concentric with the western border of the "sea," and gradually diminishing in altitude as they spread out, with many ramifications, to a distance of 200 miles or more toward the north. At this stage of illumination they are strikingly beautiful in a good telescope, reminding one of the ripple-marks left by the tide on a soft, sandy beach. Like most other objects of their class, they are very evanescent, gradually disappearing as the sun rises higher in the lunar firmament, and ultimately leaving nothing to indicate their presence beyond here and there a ghostly streak or vein of a somewhat lighter hue than that of the neighboring surface.

The Maria, like almost every other part of the visible surface, abound in craters of a minute type,[381] which are scattered here and there without any apparent law or ascertained principle of arrangement.

Walled-plains, approximating more or less to the circular form, though frequently deviating considerably from it, are among the largest inclosures on the moon. They vary from upward of 150 to 160 miles or under in diameter, and are often encircled by a complex rampart of considerable breadth, rising in some instances to a height of 12,000 feet or more above the inclosed plain. This rampart is rarely continuous, but is generally interrupted by gaps, crossed by transverse valleys and passes and broken by more recent craters and depressions. As a rule, the area within the circumvallation (usually termed "the floor") is only slightly, if at all, lower than the region outside: it is very generally of a dusky hue, similar to that of the gray plains of Maria, and, like them, is usually variegated by the presence of hills, ridges, and craters, and is sometimes traversed by delicate furrows, termed clefts or rills.

Ptolemæus, in the third quadrant and not far removed from the centre of the disk, may be taken as a typical example of the class. Here we have a vast plain, 115 miles from side to side, encircled by a massive but much broken wall, which at one peak towers more than 9,000 feet above a level floor, which includes details of a very remarkable character. The adjoining Alphonsus is another, but somewhat smaller object of the same type, as are also Albategnius and Arzachel; and Plato, in a high northern latitude, with its noble, many-peaked rampart and its variable steel-gray interior, Grimaldi, near the[382] eastern limb (perhaps the darkest area on the moon), Schickard, nearly as big on the southeastern limb, and Bailly, larger than either (still further south in the same quadrant), although they approach some of the smaller “seas” in size, are placed in the same category. The conspicuous central mountain, so frequently associated with other types of ringed inclosures, is by no means invariably found within the walled-plains; though, as in the case of Petavius, Langrenus, Gassendi, and several other noteworthy examples, it is very prominently displayed. The progress of sunrise on all these objects affords a magnificent spectacle. Very often when the rays infringe on their apparently level floor at an angle of from 1° to 2°, it is seen to be coarse, rough grained, and covered with minute elevations, although an hour or so afterward it appears as smooth as glass.

The more massive and extended mountain ranges of the moon are found in the Northern Hemisphere, and (what is significant) in that portion of it which exhibits few indications of other superficial disturbances. The most prominently developed systems, the Alps, the Caucasus, and the Apennines, forming a mighty western rampart to the Mare Imbrium and giving it all the appearance of a vast walled-plain, present few points of resemblance to any terrestrial chain. The former include many hundred peaks, among which Mont Blanc rises to a height of 12,000 feet, and a second, some distance west of Plato, to nearly as great an altitude; while others ranging from 5,000 to 8,000 feet are common. They extend in a southwest direction from Plato to the[383] Caucasus, terminating somewhat abruptly, a little west of the central meridian in about N. lat. 42°. One of the most interesting features associated with this range is the so-called great Alpine valley, which cuts through it west of Plato.

The Caucasus consist of a massive wedge-shaped mountain land, projecting southward, and partially dividing the Mare Imbrium from the Mare Serenitatis, both of which they flank. Though without peaks so lofty as those pertaining to the Alps, there is one, immediately east of the ring-plain Calippus, which, towering to 19,000 feet, surpasses any of which the latter system can boast. The Apennines, however, are by far the most magnificent range on the visible surface, including as they do some 3,000 peaks, and extending in an almost continuous curve of more than 400 miles in length from Mount Hadley, on the north, to the fine ring-plain Eratosthenes, which forms a fitting termination, on the south. The great headland Mount Hadley rises more than 15,000 feet, while a neighboring promontory on the southeast of it is fully 14,000 feet, and another, close by, is still higher above the Mare. Mount Huyghens, again in N. lat. 20°, and the square-shaped mass Mount Wolf, near the southern end of the chain, include peaks standing 18,000 and 12,000 feet respectively above the plain to which their flanks descend with a steep declivity. The counterscarp of the Apennines, in places 160 miles in width from east to west, runs down to the Mare Vaporum, with a comparatively gentle inclination. It is everywhere traversed by winding valleys of a very intricate type,[384] all trending toward the southwest, and includes some very bright craters and mountain-rings.

Whether variations in the visibility of lunar details, when observed under apparently similar conditions, actually occur from time to time from some unknown cause, is one of those vexed questions which will only be determined when the moon is systematically studied by experienced observers using the finest instruments at exceptionally good stations; but no one who examines existing records of rills by Gruithuisen, Lohrmann, Mädler, Schmidt, and other observers, can well avoid the conclusion that the anomalies brought to light therein point strongly to the probability of the existence of some agency which occasionally modifies their appearance or entirely conceals them from view. In short, the more direct telescopic observations accumulate, and the more the study of minute detail is extended, the stronger becomes the conviction that, in spite of the absence of an appreciable atmosphere, there may be something resembling low-lying exhalations from some parts of the surface which from time to time are sufficiently dense to obscure, or even obliterate, the region beneath them.

Sir John Herschel maintained that “the actual illumination of the lunar surface is not much superior to that of weathered sandstone rock in full sunshine. I have,” he says, “frequently compared the moon setting behind the gray perpendicular façade of the Table Mountain, illumined by the sun just risen in the opposite quarter of the horizon when it has been scarcely distinguishable in brightness from[385] the rock in contact with it. The sun and moon being at nearly equal altitudes, and the atmosphere perfectly free from cloud or vapor, its effect is alike on both luminaries.” Zöllner’s elaborate researches on this question are closely in accord with the above observational result. Though he considers that the brightest parts of the surface are as white as the whitest objects with which we are acquainted, yet, taking the reflected light as a whole, he finds that the moon is more nearly black than white. The most brilliant object on the surface is the central peak of the ring-plain Aristarchus, the darkest the floor of Grimaldi, or perhaps a

portion of that of the neighboring Riccioli. Between these extremes there is every gradation of tone. Proctor, discussing this question on the basis of Zöllner's experiments respecting the light reflected by various substances, concludes that the dark area just mentioned must be notably darker than the dark gray syenite which figures in his tables, while the floor of Aristarchus is as white as newly fallen snow. MARS.—Agnes M. Clerke

The furthest terrestrial planet from the sun is Mars, the "star of strength." No other heavenly body, except the moon, is so well placed for observation from our position in space.

The diameter of Mars is 4,200 miles; its surface is equal to two-sevenths, its volume to one-seventh those of the earth. But, in consequence of its inferior mean density, nine such spheres would go to[386] make up the mass of our world. The superficial force of gravity on Mars, compared with its terrestrial value, is as thirty-eight to a hundred. A man could leap there a wall eight feet four inches in height with no more effort than it would cost him here to spring over a two-foot fence.

The planet's rotation is performed in 24 hours, 37 minutes, on an axis deviating from the vertical by 24° 50′. Hence its seasons resemble our own, except in being nearly twice as long, for the Martian year is of 687 days.

The disk of Mars is diversified with three shades of color—reddish, or dull orange, dark grayish-green, and pure white. The last shows mainly in two diametrically opposite patches. Each pole is surrounded by a brilliant cap, suggesting the deposition of ice or snow over the chilly spaces corresponding to our arctic and antarctic regions. Nor is this all. Each of the polar hoods shrinks to a mere remnant as the local summer advances, but regains its original size when wintry influences are again in the ascendant. Here, and nowhere else in the planetary system, we meet evidence of seasonal change; and seasonal change is associated with vital possibilities. Again, a globe upon which snow visibly melts must contain water; hence the green markings can not but image to our minds seas and inlets subdividing continents, the blond complexion of which may be caused by some native peculiarity of the soil. It is in no way connected with vegetation, since it neither fades nor flushes with the advent of spring; and an atmospheric origin is excluded by the circumstance[387] that it becomes effaced by a whitish haze near the limb, just where the densest atmospheric strata are traversed by the line of sight.

The spots on Mars are by no means so sharply defined as lunar craters and maria; yet they are fundamentally permanent. Some can be recognized from drawings made over two hundred years ago; and these antique records have served modern astronomers to determine with minute accuracy the rotation-period of the planet. Continents are somewhat vaguely outlined. Great tracts of them are of an uncertain and variable hue, as if subject to inundations. This peculiarity, thoroughly certified during the favorable opposition of 1892, makes a strong distinction between Mars and the Earth. Terrestrial oceans keep within the limits assigned to them. On the neighboring planet—as M. Faye observed in 1892—"water seems to march about at its ease," flooding from time to time regions as wide as France. The imperfect separation of the two elements recalls the conditions prevailing during the terrestrial carboniferous era.

The main part of the land of Mars is situated in the Northern Hemisphere. It covers two-thirds of the entire globular surface. Rather than land, indeed, it should be called a network of land and water. The great continental block—so its orange tint declares it to be—is cut up in all possible directions by an intricate system of what appear to be waterways, running in perfectly straight lines—that is, along great circles of the globe—for distances varying from 350 to upward of 4,000 miles. They are frequently[388] seen in duplicate, strictly parallel companions developing thirty to three hundred miles apart from the original formations. This mysterious phenomenon is evanescent, or rather periodical.

The canals invariably connect two bodies of water; hence they need no locks or hydraulic machinery; their course is on a dead level. The broadest of them are comparable with the Adriatic; those at the limit of visibility, stretching like the finest spider-threads across the disk, have a width of eighteen miles. "The canals," Schiaparelli says, "may intersect among themselves at all possible angles, but by preference they converge toward the small spots to which we have given the name of lakes. For example, seven are seen to converge in Lacus Phœnicis, eight in Trivium Charontis, six in Lunæ Lacus, and six in Ismenius Lacus."

These "lakes" evidently form an integral part of the canal system. They resemble huge railway junctions; and the largest of them—the "Eye of Mars" (Schiaparelli's Lacus Solis)—seems, in Mr. Lowell's phrase, like the hub of a five-spoked wheel. Mr. W. H. Pickering in 1892, and Mr. Percival Lowell in 1894, were amazed at their extraordinary abundance.

"Scattered over the orange-ochre groundwork of the continental regions of the planet," the latter wrote, "are any number of dark, round spots. How many there may be it is not possible to state, as the better the seeing, the more of them there seem to be. In

spite, however, of their great number, there is no instance of one occurring unconnected with a canal. What is more, there is apparently none which does[389] not lie at the junction of several canals. Reversely, all the junctions appear to be provided with spots."

Most of these foci are about 120 miles in diameter, and appear most precisely circular when most clearly seen. "Plotted upon a globe," Mr. Lowell continues, "they and their connecting canals make a most curious network over all the orange-ochre equatorial parts of the planet, a mass of lines and knots, the one marking being as omnipresent as the other. Indeed, the spots are as peculiar and distinctive a feature of Mars as the canals themselves."

Like the canals, too, they emerge periodically, and in the same but a retarded succession. They "are, therefore, in the first place, seasonal phenomena, and, in the second place, phenomena that depend for their existence upon the prior existence of the canals."

Mr. Lowell terms them "oases," and does not shrink from the full implication of the term.

The most important result of the numerous observations of Mars, made during the oppositions of 1892 and 1894, was the recognition of a regular course of change dependent upon the succession of its seasons. Schiaparelli had long anticipated this result; he is commonly in advance of his time. These changes, moreover, when closely watched, are really self-explanatory. The alternate melting of the northern and southern snow-caps initiates and to some extent determines them. As summer advances in either hemisphere, the wasting of the corresponding white calotte can be followed in every minute particular. "The snowy regions are then seen to be successively notched at their edges; black holes and huge fissures[390] are formed in their interiors; great isolated fragments many miles in extent stand out from the principal mass, dissolve, and disappear a little later. In short, the same divisions and movements of these icy fields present themselves to us at a glance that occur during the summer of our own arctic regions."

Indeed, glaciation on Mars is much less durable than on the earth. In 1894 the southern snow-cap vanished to the last speck 59 days after the solstice and the remnant usually left looks scarcely enough to make a comfortable cap for Ben Nevis. An immense quantity of water is thus set free. The polar seas overflow; gigantic inundations reinforced, doubtless, from other sources, spread to the tropics; Syrtis regions of marsh or bog deepen in hue, and become distinctly aqueous; canals dawn on the sight, and grow into undeniable realities. We seem driven to believe that they discharge the function of flood-emissaries.

Mr. Lowell does not hesitate to pronounce them of artificial formation, and, on that large assumption, the purpose of their connection with his "oases" becomes transparently clear. They bring to these Tadmors in the wilderness the water supply by which they are made to "blossom as the rose." The junction-spots, we are told, do not enlarge when the vernal freshet reaches them; they only darken through the sudden development of vegetation. These circular "districts, artificially fertilized by the canal system," are strewn broadcast over vast desert areas, the orange-ochreous sections of Mars, covering the greater part of its surface, but deep buried in[391] the millennial dust of disintegrated red sandstone strata.

"Here, then," Mr. Lowell remarks, "we have an end and reason for the existence of canals, and the most natural conceivable—namely, that the canals are constructed for the express purpose of fertilizing the oases. When we consider the amazing system of the canal lines, we are carried to this conclusion as forthright as is the water itself; what we see being not the canal itself, indeed, but the vegetation along its banks."

The proportion of water to land is much smaller on Mars than on the earth. Only two-sevenths of the disk are covered by the dusky areas, and of late the aqueous nature of some, if not all, of these has been seriously called in question. Professor Pickering was convinced by his observations, in 1892 and 1894, "that the permanent water area upon Mars, if it exist at all, is extremely limited in its dimensions." He estimated it at about half the size of the Mediterranean. Professor Schaeberle is similarly incredulous. If the dark markings are seas, he asks, how explain the irregular gradations of shade in them? How, above all, explain their apparent intersection by well-marked canals? Professor Barnard, observing with the Lick thirty-six inch in 1894, discerned on the Martian surface an astonishing wealth of detail, "so intricate, small, and abundant, that it baffled all attempts to properly delineate it." It was embarrassing to find these minute features belonging more characteristically to the "seas" than to the "continents." Under the best conditions, the[392] dark regions lost all trace of uniformity. Their appearance resembled that of a mountainous country, broken by cañon, rift, and ridge, seen from a great elevation. These effects were especially marked in the "ocean" area of the Hour-Glass Sea.

Evidently the relations of solid and liquid in that remote orb are abnormal; they can not be completely explained by terrestrial analogies. Yet a series of well-attested phenomena are intelligible only on the supposition that Mars is, in some real sense, a terraqueous globe. Where snows melt there must be water; and the origin of the Rhone from a great glacier is scarcely more evident to our senses than the dissolution of Martian ice-caps into pools and streams.

The testimony of the spectroscope is to the same effect. Dr. Huggins found, in 1867, the spectrum of Mars impressed with the distinct traces of aqueous absorption, and the fact, although called in question by Professor Campbell of Lick, in 1894, has been reaffirmed both at Tulse Hill and at Potsdam. That clouds form and mists rise in the thin Martian air, admits of doubt. During the latter half of October, 1894, an area much larger than Europe remained densely obscured. Whether or no actual rain was at that time falling over the Maraldi Sea and the adjacent continent it would be useless to conjecture. We only know that with the low barometric pressure at the surface of Mars, the boiling point of water must be proportionately depressed (Flammarion puts it at 115° Fahrenheit), which implies that it evaporates rapidly, and can be transported easily.

[393]

If the Martian atmosphere be of the same proportionate mass as that of our earth, it can possess no more than one-seventh its superficial density. That is to say, it is more than twice as tenuous as the air at the summits of the Himalayas. The corresponding height of a terrestrial barometer would be four and a half inches. Owing, however, to the reduced strength of gravity on Mars, this slender envelope is exceedingly extensive. In the pure sky scarcely veiled by it, the sun, diminished to less than half his size at our horizons, probably exhibits his coronal streamers and prominences as a regular part of his noontide glory; atmospheric circulation proceeds so tranquilly as not to trouble the repose of a land “in which it seemeth always afternoon”; no cyclones traverse its surface, only mild trade-winds flow toward the equator, to supply for the volumes of air gently lifted by the power of the sun, to carry reinforcements of water-vapor north and south. Aerial movements are, in fact, by a very strong presumption, of the terrestrial type, but executed with greatly abated vigor.

Brilliant projections above the terminator of Mars were first distinctly perceived at the Lick Observatory in 1890. They have been reobserved at Nice, Arequipa, and Flagstaff (Mr. Lowell’s observatory), coming into view, as a rule, when circumstances concur to favor their visibility. They strictly resemble lunar peaks and craters, catching the first rays of the sun, while the ground about them is still immersed in darkness; and Professor Campbell connects them with “mountain chains lying across the[394] terminator of the planet,” and in some cases possibly snow-covered. He calculates their height at about ten thousand feet. Their presence was unlooked for, since a flat expanse is a condition sine quâ non for the minute intersection of land by water, which seems to prevail on Mars.

Although the sun is less than half as powerful on Mars as it is here, the Martian climate, to outward appearance, compares favorably with our own. Polar glaciation is less extensive and more evanescent, and little snow falls outside the arctic and antarctic regions. Yet the theoretical mean temperature is minus 4° C., or 61° of Fahrenheit below freezing. This means a tremendous ice-grip. The coldest spot on the earth’s surface is considerably warmer than this cruel average. Fortunately, it exists only on paper. Some compensatory store of warmth must then be possessed by Mars, and it can scarcely be provided by its attenuated air. Possibly, internal heat may still be effective, and we see exemplified in Mars the geological period when vines and magnolias flourished in Greenland, and date-palms ripened their fruit on the coast of Hampshire.

The climate of Mars, according to Schiaparelli, “must resemble that of a clear day upon a high mountain. By day a very strong solar radiation hardly at all mitigated by mist or vapor; by night a copious radiation from the soil toward celestial space, and hence a very marked refrigeration; consequently, a climate of extremes, and great changes of temperature from day to night, and from one season to another. And as on the earth, at altitudes of from[395] 17,000 to 20,000 feet, the vapor of the atmosphere is condensed only into the solid form, producing those whitish masses of suspended crystals which we call cirrus-clouds, so in the atmosphere of Mars it would be rarely possible to find collections of cloud capable of producing rain of any consequence. The variation of temperature from one season to another would be notably increased by their long duration, and thus we can understand the great freezing and melting of the snow, renewed in turn at the poles at each complete revolution of the planet round the sun.”

The German astronomer Mädler searched in 1830 for a Martian satellite, and although his telescope was of less than four inches aperture, he satisfied himself that none with a diameter of as much as twenty-three miles could be in existence. As it happened, he was right. The pair of moons detected by Professor Asaph Hall with the Washington twenty-six refractor, August 11 and 17, 1877, are unquestionably below that limit of size. Neither of them can well be more than ten miles across. Their names, “Deimos” and

“Phobos,” are taken from the Iliad, where Fear and Panic are introduced as attendants upon the God of War. Deimos revolves in 30 hours and 18 minutes at a distance of 14,600 miles from the centre of Mars. And since the planet rotates in 24 hours, 37 minutes, the diurnal motion of the sphere from east to west is so nearly neutralized by the orbital circulation of the satellite from west to east that nearly 132 hours elapse between its rising and its setting. During the interval, it changes four times from new to full, and vice versâ.

[396]

Phobos is more effective in illumination, both because it is larger and because it is less distant. At the Martian equator, its brightness is equal to 1/60th that of our moon, but beyond 69° of latitude it is permanently shut out from view by the curvature of the globe. THE PLANETOIDS.—Camille Flammarion

On the first day of the last century (January 1, 1801), Piazzi, an astronomer devoted to the sky, was observing at Palermo the small stars of the constellation Taurus, and noting their exact positions, when he remarked one which he had never seen before. The following evening (January 2) he directed his telescope again toward the same region of the sky, and remarked that the star was no longer at the point where he had seen it the day before, and that it had retrograded by 4′. It continued to retrograde up to the 12th, stopped, and then moved in the direct way—that is to say, from west to east. What was this moving star? The idea that it might be a planet did not immediately occur to the mind of the observer, and he took it for a comet, as William Herschel had done in 1781, when he discovered Uranus.

However, the skilful Sicilian observer was a member of an association which had for its special object the search for an unknown planet between Mars and Jupiter. From the earliest times of modern astronomy Kepler had described the disproportion, the void which exists between the orbit of Mars and that[397] of Jupiter. If we omit, in fact, the orbit of the small planets or asteroids, we notice that the four planets, Mercury, Venus, the earth, and Mars, are in some measure crowded quite close to the sun, while Jupiter, Saturn, Uranus, and Neptune extend far into immensity. The law of Titius indicates a number, the number 28, as not being represented by any planet. It was in 1772 that this savant published this relation in a German translation which he had made of the Contemplation de la Nature of Charles Bonnet. Bode, Director of the Berlin Observatory, was so astonished at the coincidence that he announced this arithmetical relation as being a real law of nature, and spoke of it in such a way that it is generally known only by his name. He even organized an association of twenty-four astronomers to explore each hour of the Zodiac and search for the unknown. This systematic exploration had not yet produced any result when, by the merest chance, Piazzi saw his moving star, and at first believed it to be a comet. But on receipt of the news, Bode was convinced that this was the looked-for planet.

The new planet was found to be at the distance 2.77, and to revolve within a few days of the predicted period. Piazzi gave to the new body the name of Ceres, the protecting divinity of Sicily in the “good old times” of mythology.

The gap being thus filled up at the distance 28 by the discovery of Ceres, no one thought that other planets might exist there; and if Piazzi had supposed so, he might have at once discovered a dozen of the small bodies which revolve in this region.[398] An astronomer of Bremen, Olbers, observed this planet on the evening of March 28, 1802, when he perceived in the constellation of the Virgin a star of the seventh magnitude which was not marked on Bode’s chart, which he used. The following day he found it had changed its place, and recognized by this fact that it was a second planet. But it was much more difficult to give citizenship to it than to its elder sister, because, the gap being filled up, it was not required, and it was more inconvenient than agreeable. They looked upon it, then, as a comet until its motion proved that it revolved in the same region as Ceres at the distance 2.77, and in 1,685 days (the period of Ceres is 1,681 days). They gave it the name of Pallas.

The unexpected discoveries of Ceres and Pallas led astronomers to revise the catalogues of stars and celestial charts. Harding was of the number of the zealous revisers. He was soon rewarded for his trouble. On September 1, 1804, at ten o’clock in the evening, he saw in the constellation of Pisces a star of the eighth magnitude which was not noted in the Histoire Céleste of Lalande. On September 4, he found it had perceptibly changed its place: it was a new planet. It received the name of Juno. Its distance from the sun is expressed by the number 2.67, and its revolution is performed in 1,592 days.

After these three discoveries, Olbers, noticing that the orbits of these planets crossed each other in the constellation of the Virgin, advanced the hypothesis that they might be nothing else but fragments of a[399] large shattered planet. Mechanics show that, in this case, the fragments would again pass every year—that is to say, at each of their revolutions—through the spot where the catastrophe took place. Olbers then set himself to explore the constellation Virgo carefully, and found on March 29, 1807, a fourth small planet, to which he gave the name of Vesta. Its distance is but 2.36, and its revolution only 1.326 days. This is the brightest of

the small planets, and it is sometimes seen with the naked eye (when we know where it is), like a star of the sixth magnitude.

It seems surprising that after these brilliant beginnings thirty-eight years should then have passed without the discovery of a single planet, for it was only in 1845 that the fifth, Astræa, was discovered by Hencke (who should not be confused with the astronomer Encke), a simple amateur astronomer, postmaster at Berlin, who amused himself by constructing charts of the stars. The principal reason for this must be attributed to the want of good star-charts, for to find these little moving points the first thing necessary is to have a very precise chart of the region of the Zodiac which we observe, in order to see whether one of the stars observed is in motion. The earliest good Zodiacal charts are those which the Academy of Berlin commenced to publish in 1830, taking as a basis the zones of Bessel continued by Argelander. Those of the Paris Observatory, which are more perfect, were only begun in 1854.

These small planets are all telescopic, invisible to the naked eye, with the exception of Vesta, and sometimes Ceres, which good sight can occasionally succeed[400] in distinguishing; they are of the seventh, eighth, ninth, tenth, and eleventh magnitudes, and even still smaller, and it was for this reason also that so long an interval of time elapsed between the fourth and fifth discoveries. It is probable that all the small planets of any importance are now known, but that a great number—several hundreds, perhaps—still remain to be discovered of which the average brightness does not exceed that of stars of the twelfth magnitude, and of which the diameter is but a few miles. The diameter of the largest, Vesta, may be estimated at 400 kilometres (248 miles).

Hencke found successively the 5th and the 6th in 1845 and 1847; Hind, the English astronomer, the 7th and 8th in 1847; Graham, an English observer, the 9th in 1848; Gasparis, an Italian astronomer, the 10th and 11th in 1849 and 1850, and afterward seven others. Hind has further discovered eight others; Goldschmidt, a German painter (a naturalized Frenchman), discovered fourteen between 1852 and 1861.[27] They are now discovered by swarms; Paliser alone has found sixty-eight since 1874.

[401]

The names given to these small bodies commenced with the mythological army of divinities of the earth and ancient heaven; but even before the list had been exhausted certain scientific, or even national or political, circumstances caused the preference to be given to more modern names. It was thus that the 11th, discovered at Naples, received the name of Parthenope; the 12th, discovered in England, that of Victoria; the 20th, that of Massilia; the 21st, that of Lutetia; the 25th, that of Phocæa, before even Urania had been restored to the skies; the 45th was named in honor of the Empress of the French; the 54th, in honor of the illustrious Alexander von Humboldt; etc. The 87th, 107th, 141st, 154th, and 169th have been named in honor of a young astronomer who has devoted his best years to the culture of astronomy.

A rather curious fact is that they have put Wisdom (Sapientia) in the sky only at the 275th, discovered in 1888; Bellona has been placed there since the 28th (1854).

Of all this number of planets, the nearest to the sun is No. 149, Medusa, of which the distance is 2.17—that is to say, about twice as far from the sun as the earth; and the most distant is No. 279, Thule, of which the distance is 4.26, about 4¼ times our distance.

A large number of these small bodies are remarkable[402] for their great eccentricity and for their high inclination to the ecliptic, an inclination so great that some of them leave the Zodiac; thus, Pallas (2) goes 34 degrees from the ecliptic; Euphrosyne (31) and Anna (265) and Istria (183), to 26 degrees. They are sometimes northern circumpolar stars, always above the horizon, sometimes southern stars, not arising above the horizon of Paris. All these orbits are so interlaced with each other that, if they were material hoops, we could by means of one or two taken by chance raise all the others.

Are they globes? Yes, doubtless, for the most part. But several among the smaller ones may be polyhedral, and may have proceeded from subsequent explosions; the variations of brightness which have been sometimes observed seem to imply surfaces irregularly broken.

Are they worlds? Why not? Is not a drop of water shown in the microscope peopled with a multitude of various beings? Does not a stone in a meadow hide a world of swarming insects? Is not the leaf of a plant a world for the species which inhabit and prey upon it? Doubtless among the multitude of small planets there are those which must remain desert and sterile because the conditions of life (of any kind) are not found united. But we can not doubt that on the majority the ever-active forces of nature have produced, as in our world, creations appropriate to these minute planets. Let us repeat, moreover, that for nature there is neither great nor little. And there is no necessity to flatter ourselves with a supreme disdain for these little[403] worlds, for in reality the inhabitants of Jupiter would have more right to despise us than we have to despise Vesta, Ceres, Pallas, or Juno: the disparity is greater between Jupiter and the earth than between the earth and these planets. FOOTNOTES:

[27] Goldschmidt passionately loved astronomy, and I have found among his papers, which his family left me, numerous observations and remarks which show how he loved the study of the sky. His greatest ambition had been, at first, to possess a small telescope, in order to make some observations, and the best day of his life was that on which he found one in the possession of a dealer in old stores. He hastened to direct it to the sky from his modest studio, situated in one of the most frequented streets of Paris (Rue de l'Ancienne-Comédie), above the Café Procope, formerly used as a rendezvous by the stars of literature. There, from his window, he discovered, in 1852, the 21st small planet, which received from Arago the name of Lutetia; then, in 1854, the 32d (Pomona); then, in 1855, the 36th (Atlanta); and afterward eleven others, all from his window. Having often removed in search of a pure atmosphere, he finally retired to Fontainebleau, where the forest offered him on all sides admirable subjects for painting; and here he died in 1866. JUPITER.—Agnes M. Clerke

Jupiter is by far the most important member of the solar family. The aggregate mass of all the other planets is only two-fifths of his, which 316 earths would be needed to counterbalance. His size is on a still more colossal scale than his weight, since in volume he exceeds our globe 1,380 times. His polar and equatorial diameters measure respectively 84,570 and 90,190 miles, giving a mean diameter of 88,250 miles, and a polar compression of 1/16th. The corresponding equatorial protuberance rises to 2,000 miles, so that the elliptical figure of the planet strikes an observer at the first glance. This at once indicates rapid axial movement; and Jupiter's rotation is accordingly performed in nine hours and fifty-five minutes, with an uncertainty of a couple of minutes.

The numbers just given imply that this great planet is of somewhat slight consistence, and its mean density is, in fact, a little less than that of the sun. The sun is heavier than an equal bulk of water in the proportion of 1.4 to 1, Jupiter in the proportion of 1.33 to 1. The earth is thus more than four times specifically heavier than the latter globe. Three Jupiters would keep in equipoise four equal globes[404] of water, while the earth would turn the scale against five and a half aqueous models of itself. This low density, an unfailing characteristic of all the giant planets, is charged with meaning. It at once gives us to understand that, in crossing the zone of asteroids, we enter upon a different planetary region from that left behind. The bodies revolving there are on an immensely larger scale of magnitude than those on the hither side; they are of solar, rather than terrestrial, density; they rotate much more rapidly, and are in consequence of a more elliptical shape; they display, and most likely possess, no solid surface; they are attended by retinues of satellites.

Jupiter circulates round the sun in 11.86 years, in an orbit deviating by less than one and a half degrees from the plane of the ecliptic, but of thrice the eccentricity of the ellipse traced out by the earth. With a mean distance from the sun of 483 millions of miles, it accordingly approaches within 462 at perihelion, and withdraws to 504 millions of miles at aphelion. Seasons it has none worth mentioning; nor could they be of much effect even if they were better marked.

Under propitious circumstances Jupiter comes within 369 million miles of the earth. These occur when he is in opposition nearly at the epoch of his perihelion passage. His maximum opposition distance, on the other hand, is 411 million miles. He is then at aphelion. Thus, at the most favorable opposition, he is 42 million miles nearer to us than at the least favorable. The effect on his brightness is evident to the eye. When his midnight culmination[405] takes place in October, he in fact sends us one and a half times more light than when the event comes round to April. We need only recall the unusual splendor of his appearance in September and October, 1892, when his lustre was double that of Sirius. His opposition period, as we may call it, is 399 days.

The intrinsic brilliancy of his surfaces is surprising, especially when we consider that it is somewhat deeply tinged with color.

The minimum diameter of the visible disk considerably exceeds the maximum of that of Mars. Even with a low power it thus makes a beautiful and interesting telescopic object. Its distinctive aspect is that of a belted planet, the belts varying greatly in number and arrangement. As many as thirty have, on occasions, been counted, delicately ruling the disk from pole to pole. They are always parallel to the equator, but are otherwise highly changeable, and can not be too closely studied as an index to the planet's physical constitution. Two in particular are remarkable. They are called the north and south equatorial belts, and inclose a lustrous equatorial zone. The poles are shaded by dusky hoods.

This general scheme of markings, however, when viewed with one of the great telescopes of the world, is so overlaid with minor particulars as sometimes to be scarcely recognizable. One can not see the wood for the trees. Lovely color-effects, too, come out under the best circumstances of definition and aerial transparency. The tropical belts may be summarily described as red; but they are of complex structure, and their subordinate features and formations[406] are marked out, under the sway of alternating and tumultuous activities, by strips and patches of vermilion, pink, purple, drab, and brown. The intermediate space is divided into two bands by a line, or narrow ribbon, pretty nearly coinciding with the equator, and rosy or vivid scarlet in hue. The polar caps are

sometimes of a delicate wine-color, sometimes pale gray.

Professor Keeler made an elaborate study of the planet with the Lick 36-inch in 1889, and executed a series of valuable drawings. With a power of 320, the disk, he tells us, “was a most beautiful object, covered with a wealth of detail which could not possibly be accurately represented in a drawing.” Most of the surface was then “mottled with flocculent and irregular cloud-masses. The edges of the equatorial zone were brilliantly white, and were formed of rounded, cloud-like masses, which, at certain places, extended into the red belt as long streamers. These formed the most remarkable and curious feature of the equatorial regions. They are the cause of the double or triple aspect which the red belts present in small telescopes.”

Near their starting-points the streamers were white and sharply defined, but became gradually diffused over the ruddy surface of the belts. When at all elongated, they invariably flowed backward against the rotational drift, and were inferred to be cloud-like masses expelled from the equatorial region, and progressively left behind by its advance. This hypothesis was confirmed by the motion of some bright points, or knots, on the streamers. “The portions[407] of the equatorial zone surrounding the roots of well-marked streamers were somewhat brighter,” Professor Keeler continues, “than at other places, and it is a curious circumstance that they were almost invariably suffused with a pale olive-green color, which seemed to be associated with great disturbance, and was rarely seen elsewhere.”

Now, if the material of the streamers had been simply a superficial overflow, it should have carried with it into higher latitudes an excess of linear rotational speed, and should hence have pushed its way onward as it proceeded north and south. But, instead, it fell behind; its velocity was less, not greater, than that of the belts with which it eventually became incorporated. What are we to gather from this fact? Evidently that the currents issuing north and south were of eruptive origin. Their motion, in miles per second, was slow, because they belonged to profound strata of the planet’s interior. Their backward drift measured the depth from which they had been flung upward.

The spots, red, white, and black, constantly visible on the Jovian surface, excite the highest curiosity. They are of all kinds and qualities, and their histories and adventures are as diverse as they are in themselves. Some are quite evanescent; others last for years. At times they come in undistinguished crowds, like flocks of sheep, then a solitary spot will acquire notoriety on its own account. White spots appear in both ways; black spots more often in communities; and it is remarkable that the former frequent distinctively, though not exclusively, the[408] Southern, the latter the Northern Hemisphere. Red spots, too, develop pretty freely; but the attention due to them has been mainly observed by one striking specimen.

The Great Red Spot has been present with us for at least nineteen years; and it is a moot point whether its beginnings were not watched by Cassini more than two centuries ago. Its modern conspicuousness, however, dates from 1878. Then of a full brick-red hue, and strongly marked contour, it measured 30,000 by nearly 7,000 miles, and might easily have inclosed three such bodies as the earth. It has since faded several times to the verge of extinction, and partially recovered; but there has never been a time when it ceased to dominate the planet’s surface-configuration. More than once it has been replaced by a bare elliptical outline, as if through an effusion of white matter into a mold previously filled with red matter; and just such a sketch was observed by Gledhill in 1870. The red spot is attached, on the polar side, to the southern equatorial belt. It might almost be described as jammed down upon it; for a huge gulf, bounded at one end by a jutting promontory, appears as if scooped out of the chocolate-colored material of the belt to make room for it. Absolute contact, nevertheless, seems impossible. The spot is surrounded by a shining aureola, which seemingly defends it against encroachments, and acts as a chevaux-de-frise to preserve its integrity. The formation thus constituted behaves like an irremovable obstacle in a strong current. The belt-stuff encounters its resistance, and rears itself up into a[409] promontory or “shoulder,” testifying to the solid presence of the spot, even though it be temporarily submerged. The great red spot, the white aureola, and the brownish shoulder are indissolubly connected.

The spot is then no mere cloudy condensation. Yet it has no real fixity. Its period of rotation is inconstant. In 1870-80, it was of 9 hours, 55 minutes, 34 seconds; in 1885-86, it was longer by 7 seconds. The object had retrograded at a rate corresponding to one complete circuit of Jupiter in six years, or of the earth in seven months. It is not then fast moored, but floats at the mercy of the currents and breezes predominant in the strange region it navigates. A quiescent condition is implied by the approximate constancy of its rotation-period during the last ten years. With the paling of its color, its “proper motion” slackens or ceases. This must mean that, at its maxima of agitation, it is the scene of uprushes from great depths, which, bringing with them a slower linear velocity, occasion the observed laggings. It is not self-luminous, and shows no symptom of being depressed below the general level of the Jovian surface.

Jupiter has no certain and single period of rotation. Nearly all the spots that from time to time come into view on its disk are in relative motion, and thus give only individual results. The great red spot has the slowest drift of all (with the rarest exceptions), while the black cohorts of the Northern Hemisphere outmarch all competitors. Mr. Stanley Williams, as the upshot of long study, has delimitated[410] nine atmospheric surfaces with definite periods. They are well marked, and evidently have some degree of permanence, yet the velocities severally belonging to them are distributed with extreme irregularity. Thus, two narrow, adjacent zones differ in movement by 400 miles an hour. This state of things must obviously be maintained by some constantly acting force, since friction, if unchecked, would very quickly abolish such enormous discrepancies. The rotational zones are unsymmetrically placed; there is no correspondence between those north and south of the Jovian equator; and, although the equatorial drift is quicker than that of either tropic, it is outdone in 20° to 24° north latitude.

Jupiter's equatorial rotation, as indicated by observations of spots, is accomplished in 9 hours 50 minutes; but Bélopolsky and Deslandres's spectrographic determinations gave rates of approach and recession falling somewhat short of the corresponding velocity. Drawings of Saturn Three Views of Saturn Showing Varying Aspects of the Ring taken at Different Intervals: 1, Feb. 2, 1862; 2, Nov. 3, 1858; 3, March 23, 1856

However this be, the rotation of the great planet, albeit ill-regulated (if the expression be permissible), is distinctly of the solar type. It is itself a "semi-sun," showing no trace of a solid surface, but a continual succession of cloud-like masses belched forth from within. Jupiter's low mean density, considered apart from every other circumstance, suffices to demonstrate the primitive nature of his state. In a sun-like body, the circulation is bodily and vertical. That the processes going on in Jupiter are of this kind is beyond question. Exchanges of hot and colder substances are effected, not by surface-flows, but by up[411] and down rushes. The parallelism of his belts to his equator makes this visible to the eye. An occasional oblique streak betokens a current in latitude, but it is exceptional, and might be called out of character.

Jupiter's true atmosphere encompasses the disturbed shell of vapors observed telescopically. Its general absorptive action upon light is betrayed by the darkening of the planet's limb—another point of resemblance to the sun; while its special, or selective, absorption can only be detected with the spectroscope.

The actinic power of Jupiter's light is very remarkable. It surpasses that of moonlight nine times, and that of Mars twenty-four times. Dr. Lohse further ascertained that the Southern Hemisphere is twice as chemically effective as the Northern. This superiority is doubtless connected with the greater physical agitation of the same region. A series of photographs of Jupiter, taken in 1891 with the great Lick refractor, were the first of any value for purposes of investigation.

Jupiter's satellites were the first trophies of telescopic observation. They are, indeed, bright enough for naked-eye perception, could they be removed from the disk which obscures them with its excessive splendor; and the first and third have actually been seen, in despite of the glare, by a few persons with phenomenally good eyesight. The mythological titles of the Galilean group—Io, Europa, Ganymede, and Calypso (proceeding from within outward)—have been superseded by prosaic numbers.

The Jovian family presents an animated and attractive[412] spectacle. The smallest of its original members (No. II) is almost exactly the size of our moon; the largest (No. III), with its diameter of 3,550 miles, considerably exceeds the modest proportions of Mercury. Satellite I revolves in 42½ hours at the same average distance from Jupiter's surface that our moon does from that of the earth. No. II has a period of 3 days 13 hours, and its distance from Jupiter's centre is 415,000 miles. Both these orbits are sensibly circular; and Nos. III and IV travel in ellipses of very small eccentricity, the one at a mean distance of 664,000, the other at 1,167,000 miles, in periods respectively of 7 days 4 hours, and 16 days 16½ hours. All four revolve strictly in the plane of Jupiter's equator.

They constitute a system bound together by peculiar dynamical relations, in consequence of which they can never be all either eclipsed or seen aligned at one side of their primary at the same time. They can all, however, be simultaneously hidden behind it, or in its shadow; although this moonless condition is looked out for as a telescopic rarity.

The transits of the satellites across the Jovian disk present many curious appearances, due to complicated and changeable effects of light and shade both upon the planetary background and upon the little circular objects self-compared with it. These, in the ordinary course, show bright while near the dusky limb, then vanish during the central passage, and re-emerge again bright at the opposite side. But instead of duly vanishing, they now and then darken even to the point of becoming indistinguishable from[413] their own shadows, by which they are preceded or followed. This difference of behavior can not be attributed wholly to varieties of lustre in the sections of the disk transited; otherwise it could be predicted. But this has never been attempted; "black transits" come

when least expected. The third and fourth satellites are those chiefly subject to these phases; the second has never been known to exhibit them; and they but slightly affect the first. Indeed, all the satellites, except, perhaps, No. II, are striped or spotted; and this leads to seeming deformations in their shape, as well as fluctuations in their brightness, the markings being evidently of atmospheric origin, and hence changeable. Their distinct and accurate perception has been made possible by the excellence of the Lick 36-inch refractor.

Jupiter's moons seem to resemble him in constitution. The first three possess the same high reflective power. No. II is as bright as the planet's brightest parts, so that its albedo can not fall short of 0.70. And even No. IV (formerly designated "Calypso" in reference to its frequent obscurations) exactly matches, during its darkest phases, the blue-gray polar hoods of its primary. On an average, too, the satellites seem to be of about the same mean density as Jupiter, No. I being considerably the lightest for its bulk; and their spectra, according to Vogel's observations in 1873, are composed of solar rays modified in precisely the same way as those reflected by the planet.

The discovery, September 9, 1892, of Jupiter's "fifth satellite" was one of the keenest astronomical[414] surprises on record. Professor Barnard seized the opportunity, lent by the specially favorable opposition of 1892, to rummage the system for novelties. Keeping the telescopic field dark by means of a metallic bar placed so as to occult the gorgeous planetary round, he sought, night after night, for what might appear. At length, on September 9, he caught the glimmer he wanted, and made sure, September 10, that it truly intimated the presence of a new satellite.

This small body revolves in a period of 11 hours, 57 minutes, 23 seconds at a mean distance of 112,160 miles from Jupiter's centre, or 67,000 from his bulged equatorial surface. Hence, it should by right be called "No. I" instead of "No. V." The major axis of the ellipse in which it circulates advances so rapidly, owing to the disturbance caused by Jupiter's spheroidal figure, as to complete a revolution in five months. The implied eccentricity of its orbit, as M. Tisserand has shown, very slightly exceeds that of the orbit of Venus, yet it has been made obvious by Barnard's observations of the differences between its east and west elongations. Its orbital velocity of 16½ miles a second far surpasses that of any other satellite in the solar system. Close vicinity to a mass so vast as Jupiter's demands counterbalancing swiftness. Its period of revolution being, however, longer by one hour than Jupiter's period of rotation, it so far conducts itself normally as to rise in the east and set in the west. On the other hand, since its progress over the sphere is measured by the difference between the two periods, it spends five Jovian days in journeying from one horizon to the other, running,[415] in the meantime, four times through all its phases. Yet it never appears full. Jupiter's voluminous shadow cuts off sunlight from it during nearly one-fifth of each circuit. SATURN.—Agnes M. Clerke

Nearly twice as far from the sun as Jupiter revolves a planet, the spacious orbit of which was, until 1781, supposed to mark the uttermost boundary of the Solar System. The mean radius of that orbit is 886 millions of miles; but in consequence of its eccentricity, the sun is displaced from its middle point to the extent of 50 million miles, and Saturn is accordingly 100 million miles nearer to him at perihelion than at aphelion. The immense round assigned to the "saturnine" planet is traversed in 29½ years, at the tardy pace of six miles a second. His seasons are thus twenty-nine times more protracted than ours, and are nominally more accentuated, since his axis of rotation deviates from the vertical by 27°. But solar heat, however distributed, plays an insignificant part in his internal economy. In the first place, its amount is only 1/91st its amount on the earth; in the second, Saturn, like Jupiter—even more than Jupiter—is thermally self-supporting. The bulk of his globe comparatively to its mass suffices in itself to make this certain. The mean diameter of Saturn is 71,000 miles, or nine times (very nearly) that of the earth; if of equal density, its mass should then be nine cubed, or 729 times the same unit. The actual proportion, however, is 95;[416] hence the planet has a mean density of only 95/729th, or between 1/7th and 1/8th the terrestrial, and being thus composed of matter as light as cork, would float in water. Professor G. H. Darwin has, moreover, demonstrated, from the movements of its largest satellite, that its density gains markedly with descent into the interior, so that its surface-materials must be lighter than any known solid or liquid.

When at its nearest to the earth, Saturn is as large as a sixpence held up at a distance of 210 yards. But instead of being round like a sixpence, it is strongly compressed—more compressed even than Jupiter. The spectra of the two planets are almost identical. Both are impressed with traces of aqueous absorption, and include the "red star line."

Saturn resembles to the eye a large, dull star; its rays are entirely devoid of the sparkling quality which distinguishes those of Jupiter. But it shows telescopically an analogous surface-structure. Its most conspicuous markings are tropical dark belts of a grayish or greenish hue; the equatorial region is light yellow, diversified by vague white spots; while the poles carry extensive pale blue canopies. The apparent tranquillity of the disk may be attributed in part to the vast distance from which it is viewed; yet not wholly.

From measures executed by Barnard in 1895, it appears that the equatorial diameter of Saturn is 76,470, its polar diameter 69,770 miles, giving a mean diameter of 74,240, and a compression of about 1/12th. Gravity, at its surface, is only 1/5th more powerful than on the earth.

[417]

Thus, Saturn not only belongs to the same celestial species as Jupiter, but is a closely related individual of that species. There is no probability that either is to any extent solid. Both exhibit the same type of markings; both betray internal tumults by eruptions of spots which, by their varying movements, supply a measure for the profundity of their origin; both possess identically constituted atmospheres, and are darkened marginally by atmospheric absorption.

Saturn is, however, distinguished by the possession of a unique set of appendages. Nothing like them is to be seen elsewhere in the heavens; and when well opened they form, with the globe they inclose, and the retinue of satellites in waiting outside, a strange and wonderful telescopic object. The rings, since they lie in the plane of Saturn's equator, are inclined 27° to the Saturnian orbit, and 28° to the ecliptic. The earth is, however, comparatively to Saturn, so near the sun, that their variations in aspect, as viewed from it, may in a rough way be considered the same as if seen from the sun. They correspond exactly with the Saturnian seasons. At the Saturnian equinoxes, the rings are illuminated edgewise, and disappear, totally or approximately; at the Saturnian solstices, sunlight strikes them nearly at the full angle of 27°, first from below, then from above. At these epochs, we perceive the appendage expanded into an ellipse about half as wide as it is long. Two concentric rings (generally called A and B) are then very plainly distinguishable, the inner being the brighter. The black fissure which separates them[418] is called "Cassini's division," because that eminent observer was, in 1675, the first to perceive it. A chasm known as "Encke's division," in the outer ring (A), is a thinning-out rather than an empty space; and temporary gaps frequently appear in A, while B is entirely exempt from them. There are then two definite and permanent bright rings, and no more; but with them is associated the dusky formation discovered by W. C. Bond, November 15, 1850, and described by Lassell as "something like a crape veil covering a part of the sky within the inner ring." It is semi-transparent, the limb of Saturn showing distinctly through it.

The exterior diameter of the ring-system is 172,800, while its breadth is 42,300 miles. The rings A and C are each 11,000 miles wide; while B measures 18,000, Cassini's division 2,270, and the clear interval between C and the planetary surface somewhat less than 6,000 miles. Each ring, C included, is brightest at its outer edge; but there is no gap between the shining and the dusky structures, B shading by insensible gradations up to C, yet maintaining distinctness from it. The earliest exact determinations of the former were made by Bradley in 1719, since when they have been affected by no appreciable change. The theoretically inevitable subversion of the system is progressing with extreme slowness.

The thickness of the rings is quite inconsiderable. They are flat sheets, without (so to speak) a third dimension. For this reason, they disappear utterly in most telescopes, when their plane passes through the[419] earth, as it does twice in each Saturnian year. Only under exceptional conditions, a narrow, knotted, often nebulous, streak survives as an index to their whereabouts. On October 26, 1891, Professor Barnard, armed with the Lick refractor, found it impossible to see them projected upon the sky, notwithstanding that their shadow lay heavily on the planet. It was not until three days later that "slender threads of light" came into view. The corresponding thickness of the formation was estimated at less than fifty miles. The phenomenon of ring disappearance will not recur until July 29, 1907.

The constitution of this marvelous structure is no longer doubtful. It represents what might be called the fixed form of a revolving multitude of diminutive bodies. This was demonstrated by Clerk Maxwell in the Adams Prize Essay of 1857. His conclusion proved irreversible. The pulverulent composition of Saturn's rings is one of the acquired truths of science. An incalculable number of tiny satellites revolving independently in distinct orbits, in the precise periods prescribed by their several distances from the planet, are aggregated into the unmatched appendages of Galileo's tergeminus planeta. The local differences in their brightness depend upon the distribution of the component satelloids. Where they are closely packed, as in the outer margins of rings A and B, sunlight is copiously reflected; where the interspaces are wide, the blackness of the sky is barely veiled by the scanty rays thrown back from the thinly scattered cosmic dust. The appearance of the crape ring as a dark stripe on the planet results—as[420] M. Seeliger has pointed out—not from the transits of the objects themselves, but from the flitting of their shadows in continual procession across the disk.

The albedo of these particles is so high as to render it improbable that they are of an earthy or rocky nature, such as the meteorites which penetrate our atmosphere. The rings they form are, on the whole, more lustrous than Saturn's globe; but this superiority is

held to be due to the absence of atmospheric absorption. Their spectrum is that of unmodified sunlight.

An eclipse of Japetus, the eighth Saturnian moon, by the globe and rings, November 1, 1889, was highly instructive as to the nature of the dusky appendage. The satellite was never lost sight of during its passage behind it; but became more and more deeply obscured as it traveled outward; then, at the moment of ingress into the shadow of ring B, suddenly disappeared. Certainty was thus acquired that the particles forming the crape ring are most sparsely strewn at its inner edge—which is, nevertheless, perfectly definite—and gradually reach a maximum of density at its outer edge. Yet, while there is not the smallest clear interval, a sharp line of demarcation separates it from the contiguous bright ring. Professor Barnard was the only observer of these curious appearances. The distribution of the ring-constituents, like that of the asteroids, was governed by the law of commensurable periods, Saturn's moons replacing Jupiter as the perturbing and regulating power.

[421]

The "satellite-theory" of Saturn's rings has received confirmation from apparently the least promising quarters. Professor Seeliger of Munich showed, from photometric experiments in 1888, that their constant lustre under angles of illumination ranging from 0° to 30° was proof positive of their composition out of discrete small bodies. And Professor Keeler of Alleghany, by a beautiful and refined application of the spectroscopic method, arrived at the same result in April, 1895. "Under the two different hypotheses," he remarked, "that the ring is a rigid body, and that it is a swarm of satellites, the relative motion of its parts would be essentially different." The former would necessarily involve increasing velocity outward, the latter, increase of velocity inward, just for the same reason that Mercury moves more swiftly than the earth, and the earth than Saturn; while the sections of a solid body, which could have but one period of rotation, should move faster, in miles per second, the further they were from the centre of attraction. The line of sight test is then theoretically available; but it was an arduous task to render it practically so. The difficulties were, however, one by one overcome; and a successful photograph of the spectra of Saturn and its rings gave the required information in unmistakable shape. From measurements of the inclinations of five dusky rays contained in it with reference to a standard horizontal line, rates of movement were derived of 12½ miles per second for the inner edge of ring B, and of 10 miles for the outer edge of ring A. The agreement with theory was,[422] as nearly as possible, exact; the components of the rings were experimentally demonstrated to be moving, each independently of every other, under the dominion of Kepler's laws.

For the globe of Saturn, Professor Keeler obtained, by the same exquisite method, a rotational period of 10 hours, 14 minutes, 24 seconds, in precise accordance with that indicated by the white spot of 1876, which thus seems to have had no proper motion, but to have floated on the ochreous equatorial surface as tranquilly as a water-lily upon a stagnant pool. The result, so far as it goes, hints that Saturn may be really, as well as apparently, less ebullient than Jupiter.

Seers into the future of the heavenly bodies consider that the rings of Saturn, like the gills of a tadpole, are symptomatic of an early stage of development; and will be disposed of before he arrives at maturity. They can not be regarded otherwise than as abnormal excrescences. No other planet retains matter circulating round it in such close relative vicinity. It was proved by Roche of Montpellier that no secondary body of importance can exist within less than 2.44 mean radii of its primary; inside of that limit it would be rent asunder by tidal strain. But the entire ring-system lies within the assigned boundary; hence, being where it is, it can only exist as it is—in flights of discrete particles. Will it, however, always remain where it is?

"Clerk Maxwell," wrote Mr. Cowper Ranyard, "used to describe the matter of the rings as a shower of brickbats, among which there would inevitably[423] be continual collisions. The theoretical results of such impacts would be a spreading of the ring both inward and outward. The outward spreading will in time carry the meteorites beyond Roche's limit, where, in all probability, they will, as Professor Darwin suggests, slowly aggregate, and a minute satellite will be formed. The inward spreading will in time carry the meteorites at the inner edge of the ring into the atmosphere of the planet, where they will become incandescent, and disappear as meteorites do in our atmosphere."

Yet it may be that collisions are infrequent in this conglomeration of "brickbats." There is the strongest presumption that they all circulate in the same direction, in orbits nearly circular, and scarcely deviating from the plane of the Saturnian equator. Those pursuing markedly eccentric tracks must long ago have been eliminated. Thus, encounters can only occur through gravitational disturbances by Saturn's moons, and they must be of a mild character, depending upon very small differences of velocity. The first sign of a "spreading outward" should be the formation of an exterior "crape ring," of which no faintest trace has yet been perceived.

Saturn's rings are entirely invisible from its polar regions, but occasion prolonged and complex eclipse-effects in its temperate and equatorial zones. They have been fully treated of from the geometrical point of view by Mr. Proctor in Saturn and its System.

Of this planet's eight satellites,[28] the largest, Titan[424] (No. VI), was discovered first (by Huygens in 1655), and the smallest, Hyperion (No. VII), last (by Lassell and Bond in 1848). The five others were detected by J. D. Cassini and William Herschel. Titan, alone of the entire group, equals our moon in size. It measures, according to Professor Barnard, 2,720 miles across. Its period of revolution is nearly sixteen days, its distance from Saturn's centre, 771,000 miles. The orbit of Japetus (No. VIII) is the largest, and its period the longest of any secondary body in the Solar System. It circulates in 79■ days at a distance of 2,225,000 miles, equal to 59½ of Saturn's equatorial radii. Hence its path is of about the same proportional dimensions as that of our moon. Japetus is remarkable for its variability in light. It is capable of tripling or quadrupling its minimum lustre. Sir William Herschel noticed that these maxima coincided with a position on the western side of the planet, and inferred rotation of the lunar kind. "From the changes in this body," he argued in 1792, "we may conclude that some part of its surface, and this by far the largest, reflects much less light than the rest; and that neither the darkest nor the brightest side is turned toward the planet, but partly one and partly the other, though probably less of the bright side."

This explanation, however, he admitted to be incomplete. There was, and is, outstanding variability, which seems to intimate the presence of an atmosphere[425] and the formation of clouds. But no positive knowledge has yet been gained regarding the physical state of Saturn's moons. We may, nevertheless, conjecture that, since tidal friction has destroyed the rotation (as regards Saturn) of the remotest member of the family, it has not spared those more exposed to its grinding-down action. All presumably rotate in the same time that they revolve.

The five inner satellites move in approximately circular orbits; the three outer in ellipses about twice as eccentric as the terrestrial path. All, Japetus only excepted, keep strictly to the plane of the rings. And since this makes an angle of 27° with the planet's orbit, eclipses are much less frequent here than in the Jovian system. They can only occur when Saturn is within a certain distance (different for each) from the node of the satellite-orbit. Even Mimas (No. I), although it wheels round the ring at an interval of only 34,000 miles, often slips outside the obliquely projected shadow-cone. Its distance from Saturn's centre is 118,000 miles, and it completes a circuit in 22½ hours. Perpetually wrapped in the glare of its magnificent primary, it is a very shy object, only to be caught sight of in its timid excursions by the very finest telescopes. Like all the Saturnian moons, except Titan, and, by a rare conjunction, Japetus, it is far too much contracted to be visible in transit across the disk.

The movements of these bodies have been carefully studied, and their mutual perturbations to some extent unraveled. They have proved exceedingly interesting to students of celestial mechanics. Titan[426] has, in this department, chiefly to be reckoned with. He exercises in the Saturnian system a similar overpowering influence to that wielded by Jupiter in the Solar System.
FOOTNOTES:

[28] A ninth satellite, Phœbe, was discovered in 1904. Its existence had been suspected for many years, and it was discovered at the Arequipa Observatory, Peru, on March 14, 1899, by means of photography. Since that date, it has been several times lost and rediscovered.—E. S. URANUS AND NEPTUNE.—William F. Denning

While Sir W. Herschel was a musician at Bath he formed the design of making a telescopic survey of the heavens. While engaged in this, he accidentally effected a discovery of great importance, for on the night of March 13, 1781, an object entered the field of his 6.3-inch reflector which ultimately proved to be a new major planet of our system.

The acute eye of Herschel, directly it alighted upon the strange body, recognized it as one of unusual character, for it had a perceptible disk, and could be neither fixed star nor nebula. He afterward found the object to be in motion, and its appearance being "hazy and ill-defined," with very high powers, he was led to regard it as a comet, and communicated his discovery to the Royal Society at its meeting on April 26, 1781.

The supposed comet soon came under the observation of others, including Maskelyne, the Astronomer Royal, and Messier, the "Comet Ferret," of Paris. The latter, in a letter to Herschel, said: "Nothing was more difficult than to catch it, and I can not conceive how you could have hit this star or comet several times, for it was absolutely necessary for me[427] to observe it for several days in succession before I could perceive that it was in motion."

As observations began to accumulate, it was seen that a parabolic orbit failed to accommodate them. Ultimately the secret was revealed. The only orbit to represent the motion of the new body was found to be an approximately circular one situated far outside the path of Saturn, and the inference became irresistible that the supposed "comet" must in reality be a new primary planet revolving on the outskirts of the Solar System. This conclusion was justified by facts of a convincing nature, and its announcement created no small excitement in the scientific world. Every telescope was directed to that part of the firmament which contained the

new orb, and its pale blue disk, wrapped in tiny proportions, was viewed again and again with all the delight that so great a novelty could inspire. From the earliest period of ancient history, no discovery of the same kind had been effected. The Chaldeans were acquainted with five major planets, in addition to the earth, and the number had remained constant until the vigilant eye of Herschel enlarged our knowledge, and Saturn was relieved as the sentinel planet going his rounds on the distant frontiers of our system.

When the elements of the new body had been computed, a search was instituted among the records of previous observers, and it was found that Herschel's planet had been seen on many occasions, but it had invariably been mistaken for a fixed star. Flamsteed observed it on six occasions between 1690 and 1715, while Le Monnier saw it on twelve nights in[428] the years 1750 to 1771, and it seems to have been pure carelessness on the part of the latter which prevented him from anticipating Herschel in one of the greatest discoveries of modern times.

The name Uranus was applied to the new planet, though the discoverer himself called it Georgium Sidus, and there were others who termed it Herschel in honor of the man through whose sagacity it had been revealed.

Uranus revolves around the sun in 30,687 days, which very slightly exceeds 84 terrestrial years. His mean distance from the sun is 1,782,000,000 miles, but the interval varies between 1,699 and 1,865 millions of miles. The apparent diameter of the planet undergoes little variation; the mean is 3″.6, but observers differ. His real diameter is approximately 31,000 miles, and the polar compression about 1/13, though this value is not that found by all authorities.

The planet near opposition shines like a star of the sixth magnitude, and is observable with the naked eye. He emits a bluish light. While engaged in meteoric observations, I have sometimes followed the planet with the naked eye during several months, and noted the changes in his position relatively to the stars near. It is clear from this that Uranus admitted of detection before the invention of the telescope.

A luminous ring, similar to that of Saturn, was at first supposed to surround Uranus, and Herschel suspected the existence of such a feature on several occasions; but it scarcely survived his later researches, and modern observations have finally disposed of it.

[429]

In May and June, 1883, Professor Young, having the advantage of the fine 23-inch refractor at the Princeton Observatory, observed two faint belts, one on each side of the equator, and much like the belts of Saturn. On March 18, 1884, Messrs. Thollon and Perrotin, with the 14-inch equatorial at Nice, remarked dark spots similar to those on Mars, toward the centre of the disk, and a white spot was seen on the limb. Two different tints were perceived, the color of the Northwest Hemisphere being dark and that of the Southeast a bluish-white color. In April observations were continued, and the white spot was seen "rather as a luminous band than a simple spot," but it was most conspicuous near the limb. The observers thought the appearances indicated a rotation-period of about ten hours. The brothers Henry at Paris, in 1884, invariably noticed two belts lying parallel to each other, and including between them the brighter equatorial zone of the planet. Their results apparently show that the angle between the plane of the Uranian equator and that of the satellite-orbits is about 41°.

M. Perrotin, with the great 30-inch equatorial at Nice, reobserved the belts in May and June, 1889. He wrote that dark parallel bands were noticed several times, and they were very similar to the belts of Jupiter. M. Perrotin notes that the bands of Uranus do not always present the same aspect. They vary in size and number in different parts of their circumference.

For many years it was supposed that Uranus possessed six satellites, all of which were discovered by[430] Sir W. Herschel, but later observations proved that four of these had no existence. They were small stars near the planet. But two of Herschel's satellites were fully corroborated, and two new ones were discovered by Lassell and Struve. The number of satellites attending Uranus is four, and it is probable that many others exist, though they are too minute to be distinguished in the most powerful instruments hitherto constructed. The following are the known satellites: 3d Ariel, discovered in 1847; 4th Umbriel, discovered in 1847; 1st Titania, discovered in 1787, and 2d Oberon, discovered in 1787.

Titania and Oberon are the two brightest satellites, but none of them can be seen except in large instruments. From observations with large modern instruments it appears highly probable that the four known satellites must be considerably larger than any others which may be revolving round the planet. A curious fact in connection with these satellites is that their motions are retrograde.

The leading incidents in the narrative of the discovery of Uranus and Neptune present a great dissimilarity—Uranus was discovered by accident, Neptune by design. Telescopic power revealed the former, while theory disclosed the latter. In one case optical

appliance afforded the direct means of success, while in the other the unerring precision of mathematical analysis attained it. The telescope played but a secondary part in the discovery of Neptune, for this instrument was employed simply to realize or confirm what theory had proven.

Certain irregularities in the motion of Uranus[431] could not be explained but on the assumption of an undetected planet situated outside the known boundaries of the system. Two able geometers applied themselves to study the problem of these irregularities, and to deduce from them the place of the disturbing body. This was effected independently by Messrs. Le Verrier and Adams; and Dr. Galle of Berlin, having received from Le Verrier the leading results of his computations, and the intimation that the longitude of the suspected planet was then 326°, found it with his telescope on the night of September 23, 1846, in longitude 326° 52′. The calculated place by Professor Adams was 329° 19′ for the same date.

The name given to the new planet was Neptune. When the elements were computed it was found that they presented rather large differences with those theoretically computed by Le Verrier and Adams. It was also found that the planet had been previously observed by Lalande on May 8 and 10, 1795, but its true character escaped detection. This astronomer had observed a star of the eighth magnitude on May 8; but on May 10, not finding the same star in the exact place noted on the former evening, he rejected the first observation as inaccurate and adopted the second, marking it doubtful. Lalande, like Le Monnier, the unsuspecting discoverer of Uranus, let a valuable discovery slip through his hands.

Neptune revolves round the sun in 60,126 days, which is equal to rather more than 164½ of our years. His mean distance from the sun is 2,792,000,000 miles, and his usual diameter 2″.7. He exceeds[432] Uranus in dimensions, his real diameter being 37,000 miles.

Our knowledge of this distant orb is extremely limited, owing to his apparently diminutive size and feebleness. No markings have ever been sighted on his miniature disk, and we can expect to learn nothing until one of the large telescopes is employed in the work. No doubt this planet exhibits the same belted appearance as that of Uranus, and there is every probability that he possesses numerous satellites.

Directly the new planet was discovered, Mr. Lassell turned his large reflector upon it and sought to learn something of its appearance, and possibly detect one or more of its satellites. On October 3 and 10, 1846, he was struck with the appearance of the disk, which was obviously not spherical. He subsequently confirmed this impression, and concluded that a ring, inclined about 70°, surrounded the planet. Professor Challis supported this view, but later observations in a purer sky led Mr. Lassell to abandon the idea. Thus the ring of Neptune, like the ring of Uranus, though apparently obvious at first, vanished in the light of more modern researches.

But if Mr. Lassell quite failed to demonstrate the existence of a ring, he nevertheless succeeded in discovering a satellite belonging to the planet. This was on October 10, 1846. The new satellite was found to have a period of 5 days, 21 hours, and 3 minutes, and to be situated about 220,000 miles distant from the planet.

END OF VOLUME ONE

TRANSCRIBER'S NOTE

Footnote [13] is referenced twice from page 102.

Obvious typographical errors and punctuation errors have been corrected after careful comparison with other occurrences within the text and consultation of external sources.

Some hyphens in words have been silently removed, some added, when a predominant preference was found in the original book.

Except for those changes noted below, all misspellings in the text, and inconsistent or archaic usage, have been retained.

Pg 3: 'Caliph Al-Mamum' replaced by 'Caliph Al-Mamun'. Pg 20: 'Ninteenth Century' replaced by 'Nineteenth Century'. Pg 21: 'Map of the' replaced by 'Chart of the'. Pg 21: 'Hourglass Sea' replaced by 'Nine Views of the Hour-Glass Sea'. Pg 74: 'cose che redire' replaced by 'cose che ridire'. Pg 74: 'Nè sa, nè' replaced by 'Né sa, né'. Pg 100: 'Hesoid' replaced by 'Hesiod'. Pg 122: 'familar to most' replaced by 'familiar to most'. Pg 150: 'formed of myraids' replaced by 'formed of myriads'. Pg 223: 'may be interred' replaced by 'may be inferred'. Pg 238: 'Will some motral' replaced by 'Will some mortal'. Pg 292: 'its orbitual motion' replaced by 'its orbital motion'. Pg 380: 'the Mare Humorom' replaced by 'the Mare Humorum'. Pg 390: 'present themelves' replaced by 'present

themselves’. Pg 391: ‘Mr. Lowell remarks,*’ replaced by ‘Mr. Lowell remarks,’; (the * anchor had no footnote and has been removed). Pg 396: ‘permamently shut’ replaced by ‘permanently shut’. Pg 418: ‘is a thining-out’ replaced by ‘is a thinning-out’.

HANDBOOK ON DRESS AND CLOAK CUTTING,

BY CHAS. HECKLINGER.

1884.

NEW YORK: PETER DE BAUN, PRINTER, 101 AND 103 FULTON STREET.

Entered according to an Act of Congress in the year 1884, by

CHARLES HECKLINGER,

in the Office of the Librarian of Congress, at Washington, D. C.

PREFACE.

The following pages contain the author's Improved System of Dress and Cloak Cutting, fully explained, with the intention of helping those students who, desirous to follow this branch of industry, are met on the very threshold by a difficulty—the choice of a suitable System.

The System given has been found to give the greatest security in its results, with the least trouble, it being easy to learn, readily used, and gives the greatest satisfaction to the large number of those using it. Everything in illustrating and explaining has been omitted which might tend to complicate or retard the student in acquiring it. Every point needed to make it clear has been carefully put down—in its illustrations, in the simple description, and in grouping the separate articles in their correct places—making it at once easy to comprehend and perfect as a whole.

[Illustration]

[Illustration]

PROPORTIONATE SYSTEM.

Most Systems of proportion, thus far issued, are projected on the breast-measure. It will be evident, on investigating the proportions of the human figure, that a System based only on one size of the body, and that its width, can never lead to the best results.

[Illustration]

When the height and width are equal it is immaterial which we use. But this is only the case on normal sizes, from 34 to 38 breast, as all deviations from these sizes are different in their proportions of heights to the widths.

The problem to be solved in using a proportionate system is to arrange the lengths so that they agree with a certain breast size and use it for the heights.

In practice we find that the average forms, measuring from 34 to 38 breast, require and can be cut by the full breast-measure, as the lengths agree, in the majority of cases, with this size; but in larger and smaller sizes this breast-measure will either be too small or too large, therefore, in drafting any other sizes than those indicated, we must use the quantities as given in the following Table, as set opposite the full breast-measure, in order that the pattern in its length may be of correct size, and neither too small or too large.

Table of Sizes.

=======+================+======= | SIZE TO DRAFT | BREAST.| ONE-HALF | WAIST. |BREAST-MEASURE.| -------+---------------+------- 30 | 15½ | 22 31 | 15■ | 22½ 32 | 16¼ | 23 33 | 16¾ | 23½ 34 | 17¼ | 24 35 | 17■ | 24½ 36 | 18 | 25 37 | 18½ | 25½ 38 | 19 | 26 39 | 19½ | 26½ 40 | 20 | 27 41 | 20¼ | 28 42 | 20¾ | 29 43 | 21■ | 30 44 | 21■ | 31½ 45 | 21 | 33 46 | 21■ | 34½ 47 | 22¼ | 36 48 | 22¾ | 37½ 49 | 23 | 38½ 50 | 23¼ | 39 -------+---------------+-------

In considering the human body it must be allowed that sufficient and marked characteristics exist between a young girl and the full-grown woman—the slender, and the large, fleshy form. All these tend to establish that the first elements of a good System for constructing garments is a good proportionate standard.

[Illustration]

In strict accordance with this we have given diagrams, illustrating the system by which the art of cutting is thoroughly attained; we also give the system as it should be used in drafting by measure.

Table of Sizes for Children.

====+========+========+========== AGE.| BREAST.| WAIST. | LENGTH OF | | | BACK TO | | | NATURAL | | | WAIST. ----+--------+--------+---------- 2 | 22 | 22 | 9 3 | 22¾ | 22¼ | 9½ 4 | 23½ | 22½ | 10 5 | 24¼ | 22¾ | 10½ 6 | 25 | 23 | 11 7 | 25¾ | 23¼ | 11½ 8 | 26½ | 23½ | 12 9 | 27¼ | 23¾ | 12½ 10 | 28 | 24 | 13 11 | 28¾ | 24¼ | 13½ 12 | 29½ | 24½ | 14 13 | 30¼ | 24¾ | 14½ 14 | 31 | 25 | 15 15 | 32 | 25 | 15½ ----+--------+--------+----------

[Illustration: Fig. 1.]

[Illustration: Fig. 2.]

THE MEASURES.

The measures required are few, and only such as give correct results (See Fig. 1).

Have a tape which fastens around the waist in such a manner that it will be level.

Measure from socket bone at top of back, point O, to waist I below the tape to B, for the highest part of hip, and to the full length of garment wanted.

Take next the width of back from E to D, being careful to see whether the dress worn has this width in the correct place. Should it be either too narrow or too wide modify your measure as seems right.

Take the measure around the arm-hole; then move the arm forward to allow you to put the tape directly under the arm to seam of sleeve at F, and measure down to bottom of tape at J.

Next, put the tape under the arm, close up, and measure the length of the sleeve down to the wrist.

Turn to Fig. 2, and measure, as shown, from back of neck, point O, past the front of arm, to bottom of tape at J. This measure must be taken easy, and should run straight down in front of arm.

Measure next from front of arm to centre of back. To take this measure, a little square, having a tape attached, is very handy to use.

Take the breast-measure over the fullest part of the bosom and shoulder blades, then the waist-measure, always taken close, and the hip-measure.

These are all the measures required for a dress-waist, a jacket, or a long garment. For a skirt we take the length on the side, from the hip down to the floor. For a circular take the width around the shoulders.

FIG. 3 AND 4. THE WAIST PATTERN.

Commence by drawing line O on the edge of a sheet of paper from point O to F, and one line C at right angles with it from O to N.

From O go down three-fourths of an inch for the actual top of back.

From O to C is one-quarter of the breast-measure, which for a 36 bust would be 9 inches, and from C over to 16 draw line D (see Fig. 4) at right angles with the back line.

Next, measure from ¾, or the top of back down to F, the length of back, from socket bone to the natural waist and from F draw a line over to the front at T.

From F go in 1½ inch, and draw a line for the centre of the back, from ¾ at top to 1½ at the bottom.

From O over on the top line, place 2 inches to the point marked ■. This will be about right for all medium sizes. For large sizes, over 40 breast, make it 2¼ inches to 2½ inches and for sizes under 30 breast-measure let it be 1½ to 1¾ inches. It will make no difference in the fit what this width may be, as it only affects the appearance of the shoulder-seam. A little practice, however, will enable any one to apply the right width.

In the middle, between O and E (see Fig. 4), fix point B, and in the centre, between B and E, locate point C, and draw lines B and G from both points.

Starting at E, measure over to S one-third of the breast, which is 6 inches for a 36; and add to it one inch, which fixes S; and from S to H place one-fourth, or 4½ inches. All fractions and divisions that we use in explanation are based on the breast-measure, and are found already divided on the square.

At S and H draw lines up, as shown. Where lines S-J and B-J cross, begin by drawing another to the top, at A.

Now, curve from ¾ to A, and from A to G, which last point is one-half inch above J. Commencing at G curve past J to R, going a trifle inside of straight line, then from R past X to V.

From R draw a straight line to 1½, and curve the back seam from R by going only a little inside of straight line at 19, thence to 2. Point 2 is 1½ inches from centre 1½. From 2 to 1 place 1 inch, then curve the side-body from 19 to 1.

Next, measure from the centre of the back at Z, on the line under the arm, to get the point D in front. This should be one-half of the breast-measure (18). Point D being placed, draw a line from there up and down to N and to U, at right angles with the line under the arm.

[Illustration: Fig. 3.]

To form the neck we take one-sixth of the breast and place it from N to P, and, using N as a pivot, sweep from P to 15. One-quarter inch inside of front line at 15 we start to draw the curved front line to the bottom, by going outside of D one-half inch and coming back to straight line again, near U.

One and a half inches below the waist-line, at U, draw a line from T over to 12.

From P to B draw a straight line; then take the length of the back shoulder, from A to G, and place the same from P towards 17, and where this reaches is point 17.

Having located 17, curve from it above the line of shoulder at 21, and drop one-fourth inch below it at 20; and, also, from 20 draw the arm-hole past 18 to X; but do not quite touch A, and drop below V one-fourth inch.

Point V is midway between S and H; from it draw a straight line to 4; curve a little on both sides of it; that is, starting from V, keep following the line for two inches, then gradually separate towards the waist-line, so that you will have two curves, which will be apart one-fourth inch near waist, but coming together again at 4.

About one-half inch more forward than the middle, between 19 and V, fix point X; and in the centre, between 1 and 4, locate 3; then draw a line from X to 3 and curve it.

In the middle, between H and D, mark point 12, and in the middle, between 12 and H, point 13.

Measure the distance from front, at U, to 1, and from 2 to 1½; on this draft it will be 16 inches. Now deduct from this the size of waist, 12 inches, and the remainder, 4 inches, must be taken out in darts. We put them in as follows: From U to 5 place a distance of 2 inches for all average medium sizes; from 5 to 6 is one dart of 2 inches, and between the darts, from 6 to 7, is three-fourths inch, then from 7 to 8 is another dart of 2 inches.

Take two-thirds of the distance under the arm and place it upwards from 7 towards 13 for the height of the back dart, and let the front one start one-half inch lower; then draw them, as shown, from 22 and 23 to 9, 10, 11 and 12.

Now, at one-fourth inch below 1, curve the lower line past 3, and a trifle above it, to 12, drop point 12 a little below the line; also drop 10 a little below it; from 9 to T remain on the line straight across.

The draft is now finished by proportion, and we can assure our readers that, with the use of the sizes on our Proportionate Table, it is applicable to all forms, the manner of drafting remaining the same in all cases.

All our figures, unless otherwise stated, are drafted without seams. We do this because it is far easier to add the amount necessary on different material than to draft it on the pattern.

THE WAIST, BY MEASURE.

The measures we shall use are the following: Breast, 36; waist, 24; length of natural waist, 15; height under arm, 7; front of arm, 10½; width of back, 6½; front length, 18½.

In drafting this we drop proportion altogether and use only the measures as stated above to get all points on the draft. All the lines and curves will come out in similar manner to the previous draft. Fig. 4 starts by drawing a line O-F and O-N; go down from O three-fourths of an inch, and in from O, to A, two inches, and curve from ¾ to A.

From ¾ down, measure the length of back 15 inches to F, and at F draw a line over to the front and go in 1½ inches and mark a point.

From ¾ to this last point draw a straight line for the centre of the back.

Up from F measure the height under arm 7 inches to E, and from E draw a line to the front.

From Z to D is one-half of the breast-measure, and draw the front line up and down. Also measure from Z to S, the actual width of the back, and from Z to H, the front of the arm, 10½ inches, or the blade measure which is taken from the front of the arm over the blade to the centre of the back. At S and H draw lines up.

In the middle between O and E mark point B, and in the middle between B and E point C, and draw the lines across as shown. (See Fig. 4.)

From where the lines cross at J, draw one across to top of back at A, and curve from A to G which point is one-half inch above J.

Beginning at G curve arm-hole past J, a trifle inside of line between J and R, and from thence to V. This last is midway between S and H.

Make the bottom of the back 1½ inches wide. This is only a medium, as it can be made 1 inch or 2 inches, which only places the seam either further back or more to the front. Then from R draw a straight line to 1½ and slightly curve a line drawn to 19 and to 2. Between 19 and 2 curve more towards centre of back. A few trials will enable you to make a nice shaped curve.

[Illustration: Fig. 4.]

From 2 on back to side body at 1 is 1 inch, and curve from 19 to 1.

From V, straight down, draw a line to 4 and curve a trifle on either side of it, also separate side-body from X to 3. Point X is midway between line R and V and the distance between 3 and 4 is about ½ inch more than X to V.

Take ■ of the breast, equal to 3 inches, and place it from point N to P and use point N as a pivot and sweep from P to 15.

At a point on waist-line directly under H, measure up past P, shoulder point, the front length, which is in our measure 18½, deducting the width of top of back, and wherever it reaches to is point P. This may, sometimes, when the person is erect, reach above the line; and again, on hollow or stooping shoulders, be below it. Wherever it reaches is the shoulder point, and when it goes above we sweep at a point above N even with shoulder for neck, and of course, should it be below the line, at a point below N, so that the neck will keep its shape to harmonize with the height of shoulder point.

[Illustration]

Wherever point P is located by measure, above or below, or on the line, start to draw the line to B, on back, for height of shoulder, and place the width of back shoulder from A to G on this line from P to get point 17. Then from 17 curve above it about one-quarter inch to P, and also draw the arm-hole, going inside of line H, but never over one-half inch, to V, as shown on the diagram. Drop a trifle from 17 to 20.

At the front, draw the line starting inside of straight line of 15 one-quarter of an inch, gradually curving out till at D we have one-half inch curve, and thence going in again to the line at waist, point U. From U go down 1¼ inch to T, and draw a line across to 12.

Measure the distance F to U, leaving out the opening between 1 and 2, which in this case will be 16 inches. Now, one-half of waist-measure, 12 inches, from 16 leaves 4 inches, which must be taken out in darts.

To produce the darts in the right place we proceed as follows: first locate a point in the middle between H and D which gives 12, and in the centre between H and 12, another which is marked 13.

From U to 5 place 2 inches, as we never wish to have the first dart any nearer to the front, then from 5 to 6 is one dart of 2 inches or one-half of the amount to be taken out. Between the darts leave three-fourths inch, and then place another dart of 2 inches from 7 to 8. In the centre of each dart mark a point and draw lines from these to 12 and 13.

One-third of the height under arm from 13 locates 23 while 22 is one-half inch lower, and starting from each of the last points curve the darts as shown.

It will be seen that they are drawn very pointed at top, and that below the waist-line they run straight down without any spring being given.

From 1 curve to 3 and 4; but between 3 and 4 it runs a trifle above waist-line, and then from 4 to 12 on lower line. Point 10 is a little lower than the line, while it rests on line, from 9 to T.

This finishes the draft by measure, and we have only to add that this, as well as the preceding, requires the adding of seams according to material used.

FIG. 5. LARGE SIZE WAIST.

In using this by measure, draft in the same way as explained in another article, the difference being only that the measure will be larger. We will explain this by the Proportionate Method: Breast, 44 inches; waist, 31½; drafting size, 21■, or equal to a breast-measure of 43¼ inches.

It should be understood that this last size of breast is used only for the height, while the original breast-measure must always be used for the width.

First draw line O-C, mark point O, and draw a line at right angles with O-C, to A; from O go down three-fourths inch to point 7, the top of back. From 7 to C is the length of the waist, 15½ or 16 inches.

[Illustration: Fig. 5.]

At the waist go in 1½ inch from C; draw a straight line from 7 to 1½ for the centre of the back.

From O go down to point B, one-quarter of the drafting size, which is, in this case, 10■ inches; this is one-quarter of 43■, as on large sizes the length is reduced in the shoulders to the drafting size. Now draw a line from B to H, and one from C to J.

Point D is in the centre between O and B; then from D draw a line over to K.

From B to G is one-third and 1 inch, equal to 8■ inches, and from G draw a line up.

From G to E is one-fourth, equal to 5¼ inches; here also draw a line up.

From N, on the back line, to H, place one-half of the full breast-measure, which is 22 inches; and at this point draw a line up and down, thus making the front line A-J.

From O to 6 is one-eighth of breast, 2■ inches. From 7 curve to 6, for the top of back, at neck; from K to 6 draw a line, and at 6 begin to curve the line for shoulder, raising it one-half inch above K to 8. Also commence to curve the arm-hole from 8, going inside

of line one-eighth inch at 16, and thence past 15 and 4 to E.

Midway between K and G is point 16. Start to make the seam for the back from 16, past 17 to 1; the last point is 1½ inch from 1½. When it is desired to produce a narrow shoulder, raise the seam above 8 one-half inch, and back from 8 fully 1 inch, and draw the arm-hole from 18 to 16.

To draw the first side-body, place 1 inch from 1 to 2, and curve the line from 16 to 17; thence separate and curve nicely to 2.

In the centre, between G and E, mark point 4, and draw a line straight down, which will be 5; and, in the middle, between 17 and 4, fix point 15. Also take the distance from 2 to 5, and fix a point in the centre, which will be 3, and then draw a line from 15 to 3; curve a little on each side of these two lines, as shown.

In producing the front, be very careful to follow the instructions as here given: From A to F is one-sixth of the breast-measure, 3½ inches; and the same amount from A to I; now, sweep from F to I, using A as pivot; from F to D draw a straight line, and place the same distance, as on the back shoulder from 6 to 8, on to F to 9, and then curve it a little above the line at 20; finish the arm-hole by curving it from 19 downwards past E. It will be seen that it runs over and in front of line E, and one-fourth inch below breast-line at 4.

For the front edge, commence one-fourth inch inside of straight line at I, and go gradually out to one-half inch at H, and in again until it touches line at J and 14.

Now to manage to fix the darts: Measure from 1½ to 1-2, to 3, and 3 to J; this will give 19½ inches. But as the measure is only 15¾, one-half of 31½, we take out the difference between these two widths in darts. This amounts to 2¾ inches, which we take out in two darts of 1■ inch each.

First find the centre between H and E, which fixes point R; and the centre, also, between R and E, which gives point P. This first dart commences 2¼ inches from J. Then put in one dart of 1■; inch. Between the darts, let the space be 1 inch, and then place the width of the other dart, which is also 1■ inch, and fix a centre in each dart.

From R draw a line through the centre of the first dart, and from P one through the centre of the second; then curve the lines of both darts like those on the diagram. The darts are started two-thirds of the distance up under the arm, but the front one is made one-half inch shorter.

From J go down 1½ inch and draw a line across to 10.

The bottom of the waist is straight from 14 to 13. At 12 begin one-fourth inch below and draw to the line at 11. From 10, also one-fourth inch below, draw a curved line to 5, raising to 3, and back to 2.

When the back has been narrowed on the shoulders it becomes necessary, also, to conform the front to it; as we have raised above 8 to 18 one-half inch, therefore, we must reduce the shoulder on the front the same amount we added, and it will bring it to 19. Then the waist is finished. Let it again be stated that seams must be added, except in the neck and arm-hole.

FIG. 6. LOW NECK DRESS WAIST.

It will be seen that the general arrangement of this draft is the same as all produced by this System.

The pointed basque-like shape at bottom is made to whatever length desired, only, it will be noticed, they are made short on the side just over the hips.

[Illustration: Fig. 6.]

In making these waists low in the neck, the first point to be considered is that they reach down lower on the shoulders, and, therefore, we have to draft them so as to meet this requirement.

From S, the original shaped draft, we go out to 10, on line D-10, 1 to 1½ inch, according to the lowness of opening; the same is added from Q to R, and the arm-hole drafted from these two last points.

Now, decide how low it should be open, and draw the curved lines from T to Q, and from B to 9. The strap on shoulder can be made 1 or 2 inches wide. If a short sleeve is wanted flatten the sleeve-head about the same amount as was added to the shoulder

over S to 10.

FIG. 7. BASQUE PATTERN.

This figure represents a short pointed basque as it can be produced by this System—whether by proportion or by measure. We have already fully explained the manner of producing all the upper portions of the draft in previous articles, and it is not necessary to go over it here again, it being the same as any other waist.

[Illustration: Fig. 7.]

From the waist down we place whatever length is wanted in the back to get point J or line B. From 1 and 1½ lines are drawn down, and whatever is put on from S to back line must be also added from line at 30 to 28.

[Illustration]

On a short basque the back line does not touch point J, it having less spring, and therefore the width of back, at S, is only a little more than at the waist, or about one-half inch on each side of the straight lines.

From J to 28 curve up, to taste. If wanted with a high curve at side, over the hips, it may reach above 28; and when desired straight around the bottom draw it along bottom line, or similar to a jacket, as shown on other Figures.

The side-body at bottom must start at S, level with 28, rising up towards R.

Q is even with R, and from it to O draw the line a little lower.

Point P is also level with O; thence, forward, it is drawn so that the front point is either level with the back or longer pointed, as shown on the Figure, where it is two inches lower.

The darts are placed the same as on a waist. But below the waist line F they curve, as shown. The best way to produce a good result is to draw straight lines down from 11, 12, 13 and 14, drawing them inside or outside of these lines, as shown. It will thus be seen that 23 comes nearly in the centre of the second dart, because more curve is here needed for the hips, while the space between the darts is drawn so that the distance between 24 and 25 is only a little more than at 12 to 13. In this way, when the darts are sewn up they will take the shape, or the seams will shape themselves like the centre-piece between the darts.

When dividing the side-body, from 18 to 19, directly under the arm draw a straight line down and let the spring on each side of this line be equal, as P and O. Also take out about one-fourth inch above the waist-line along the side-body seams, to curve them more to the shape.

From 15 to 20 a straight line is also drawn, and an equal amount is put each side of this line, over the hips, to R and O.

It will be noticed that point 18 is in the middle, between line E and the line K, or point S on Fig. 4; and point 15 is midway between 18 and line K; the width of the side-body, at the waist, is made wider; the line from 18 is always drawn straight down, then divide the distance from point 19 and 2, the centre of which is 20; and from 15 through 20 draw the other line.

FIG. 8. POLONAISE.

This is drafted in the same manner as the one given in Fig. 7. As, however, this is a long garment the amount of drapery must be increased; therefore below the hip line D we spring out till at bottom, point F, it amounts to one inch. At 4 there is one inch over line; at 6, on side-body, one inch; there draw a straight line from 4 down, through this inch, and curve the one-half inch over it. On the side, from 5 to 7, is 1½ inches, the same at bottom.

[Illustration: Fig. 8.]

Where 3 and X, of fore-part, are located lay the side-body on top of it, 1 resting on 3, and point 3, of side-body, resting on X, then finish the line from X to 14, by the way the side-body lays, and fix the length also by the side-body. Put in two darts, letting them run only 4 inches below the hip line.

FIGS. 9 AND 10. THE SLEEVE.

[Illustration: Fig. 9.]

Commence by drawing lines O-E and O-F. Use the arm-hole size to produce the sleeve, and go down from O to B one-fourth of this; A is in the middle between O and B. Draw lines across.

From O to F is one-half of arm-hole, and from there draw a line down to K.

From B to F draw a straight line and halve it, which will be point H; and from this last also draw a short line at right angles with the diagonal line from H to J.

Measure the length of line B-F and take one-third of it and place it from H to J.

Now, using J as pivot, sweep from line at top, point 4, around to the front and the back; from B curve line past 5 to this sweep. Where the sweep crosses line at G draw a line down to K.

Go down from B to C three-fourths of an inch, and from here measure the length of arm to E.

Mark a point midway between B and E, which gives D, and draw a line across.

In the middle, between the two parallel lines at back, mark a point _f_.

Now lay the square in such a position on the pattern that 5 inches will touch point E and the long arm will touch _f_, then draw along the bottom, from E to N, and to _f_.

[Illustration]

Begin to curve from C, past L to _f_, and curve to N.

Go in from D 1½ inch and draw the front-seam of the sleeve.

From X, where the curve strikes line B, begin to draw the under-sleeve parallel with upper part 6 to 1.

Measure from B around the sleeve-head to C, and apply number of inches obtained to X, and measure past 1 towards 3, the measure of arm-hole, and 2 inches more. If the upper-sleeve measures 11 inches place 11 on to X and measure 16 inches, adding 2 inches more to line at 3 for a 16-sleeve. Wherever point 3 is located begin to draw back arm-seam to bottom by running straight down, curving out to 2, or as much inside of line 7 as _f_ is outside of it.

FIG. 10.

Draw the line O-G and O-F. From O to C go down one-third, less one-half inch, and draw line over to K. In the middle, between C and O, draw also a line from B to H.

[Illustration: Fig. 10.]

From O to G is one-half of arm-hole size, and draw a line from G downwards.

From C begin to curve the sleeve-top past I to H, touching the top line at I. From L to E apply the length of sleeve. Make F 1¼ inches lower down than E.

From E to N is an average of 5 inches. Draw a line from H past K to M and N, curving it inside of K about one-half inch and curve the line only a trifle below the elbow. Go in from D 1½ inch, and draw the inside seam from C to E.

This finishes the upper-sleeve. For the under-sleeve draw from C, curving under straight line to L, thence to J. Point J is 1 inch inside of H. From J draw down to within one-half inch of M and to N.

The front-seam is the same as the upper-sleeve from C to E and N.

In drawing any sleeve use the measure of the arm-hole, and bear in mind that this manner of drafting has the seams already included.

FIG. 11. SKIRTS.

Cutting and making a dress skirt, of any style and kind, is sometimes considered of very little importance. By many dressmakers the work is entrusted to inexperienced hands and blocked out by a pattern which will not fit the form. Many fine costumes lack style

because the laws of cutting skirts for the different figures have not been observed.

The fashion for the present, and for some time past, requires the skirt to be fitted with as much care as any other part of the dress. All fullness must be so arranged as to fall into the back breadths of the train. The sloping of the bottom must be proportionate, so as to give a straight even effect across the front and sides and allow the train to suddenly spring out at the lower part of the back widths.

[Illustration: Fig. 11.]

The careful sloping of the gores at the sides causes the train to fall into a fan-like sweep. The necessity of fine slopes, and a difference of those in different costumes, as well as for different figures, will be readily appreciated when we observe the use for which the dress is intended.

In a walking dress, as it should be to be in harmony with style and the present demands of fashion, the skirts should adhere closely all around the front and sides, leaving whatever fullness there may be at the back. In order to gain this, darts are required between the breadths, which reduce the size needed over the hips down to the size at waist. As the hips proportionately increase at a given ratio at the sides it must be evident that, in order that the skirt may fall down fairly over the hips, these darts at side must be larger there, while towards the front they must be smaller.

The bottom should have a regular sweep. This sweep can be gained the easiest by laying the gores in a closing position on the table, drawing a straight line along the centre of the front and extending upwards about the same length as the skirt. At the centre of the back breadth another line is drawn far enough up to cross the first line. In this shape the two lines would represent a cone; at the point attach a string to a pin driven into the table, and extending this string to the lower length of the skirt sweep around the bottom—this will produce a correct effect in every case.

The front width is now cut wide enough so that only one additional width is needed at each side. As we have already said, much depends upon goring the sides as regards fitting the hips, but on stout ladies extra care must be taken that the front be also sufficient to cover the round form of the body. The defect liable to occur in this point has the same result as not sloping enough at the side for large hips, namely, the skirt will hitch-up on the waist-band.

Putting on a skirt to the band is of equal importance. A dart in the apron or front width gives sufficient fullness over the round of the body in front; so also do darts at side. All the rest of the fullness should be pleated or gathered into the few inches left of the band after the front and sides have been sewed to the band.

We should not advise any one to cut out a skirt, whether short or with train, with out a good pattern, unless they understand how to draft one and know the points of the different shapes in gores.

Such skirt patterns we are prepared to forward to any address, on application, but in order that students may acquire an idea of how to cut them, Fig. 11 will show the general form and shape of them.

Draw line A, and make it 45 inches long, and mark off all the distances on the line, as shown by the number of inches given at all these points; draw lines across at right angles to line A.

Draw a line from point 6 to 12 and curve it to within one-half inch of 6, and then curve slightly one-half inch below line at centre to 6½ on line A. This finishes top of front breadth; connect 12 and 45, which finishes the bottom.

Finish the top of side-breadth by drawing lines from 7 to 11, curving these lines like Figure; at the bottom, curve from 12 to 42.

Connect points 32 and 42, also 22 and 12, by straight lines, which finishes the back part; this will give a skirt 38 inches long and the prevailing width.

Lay the front part, line A, on the fold of the goods.

In sewing to the band the front and side-breadths are left plain while the back is pleated in three or four large pleats.

FIGS. 12, 13, 14. SACK JACKET.

It will be seen that every shape and style of garment must be drafted in the same manner as the principle employed in the construction of the waist-body or basque.

We first commence to draw the back line B and O to F (Fig. 12).

[Illustration: Fig. 12.]

[Illustration: Fig. 13.]

From O down, on the first line, place three-fourths of an inch, and from O over to F, one-eighth of the breast-measure, or simply 2 inches, on average size.

Starting at ¾, measure down to C, the length of natural waist, and to D, the full parts of the hips; also to E the length wanted.

From C up to B place the height under the arm. Now at every one of these points draw lines across, all at right angles with the first line.

Go in from C to N 1½ inch, and then draw a line from ¾, at top, to N, and from the last point to E, and curve the back-line, as shown from ¾, past R.

From N to M make the width of back, at waist, 2 inches or more, as desired.

Starting at R, place the width of back to G and draw a line up to S.

In the middle, between O and B, fix point A, and from there draw a line over to J.

From the point where lines A-J and G-S cross draw a line to F.

Raise above J one-half inch to S and curve the shoulder from F to S; then from S go inside of line at J and curve the arm-hole of the back to I. This last point is midway between J and G.

From I draw a line to N, then commence at I and draw line for the side-seam to 8, going inside of straight line a trifle and thence with a decided curve to M.

Draw a right-angle line with the waist-line F down to 3 from N, and to 4 from 2.

Now whatever the distance E is drawn from 3 must be placed from 4 to 5, and the back may be finished by drawing the line from 2 to 5.

In case it is desired to make a narrow back, point E may be nearer to 3; in such case point 5 would also be nearer to 4.

Cut the back out, and in order to draw the side-body lay it on the paper in such a manner that there will be room enough to cut it out without piecing.

THE SIDE-BODY.—FIG. 13.

Lines D-F and O are extended over. From 2 to 10 is 1 inch in every case.

Draw from I, along the back, to 8, and from thence begin to separate from the back and curve to 10 and down to 6, which is the point on the back where line O and the line from 2 downwards cross. From 6 down give this line a nice curve, not springing out too much nor making it too flat—a medium is what is desired.

From B to K is one-fourth of the breast-measure.

Curve from I to H and K.

About 1 inch inside of K draw a line down to L, which should make the side-body as wide from 8 to H as 10 to L.

At right angles with waist-line draw one down from 10 to 3, and another from L to 4.

Now whatever the distance is from 3 to 5 should be placed from 4 to 6, and then the seam from L is drawn past 11 to 6.

Make the length at bottom one-half inch longer at 5 to 6; also notice that the distance from 7 to 11 may be a little more than that from 9 to 6, as more ease over the hip, at side, is desirable.

THE FRONT.—FIG. 14.

All the lines are extended over on the paper, and the side-body and back are laid in the position as when they were drafted, and as shown.

First measure from B to V, one-half the breast-measure, and draw line A up and down.

From B to R is the measure to the front of the arm, where a line is drawn up. From P back, place one-sixth of the breast to N, here draw a line up and down, as shown.

[Illustration: Fig. 14.]

Measure up from star on side, marked Z, to line at N, the front length less the width of the top of back, and where this reaches on the line fix the height.

From this height draw a line to A, which gives the height of shoulder.

From P as pivot sweep from N to 21 for neck. Place the length of back shoulder from F to S on to N, on line N, and where it reaches will be point 22.

Drop one-half inch below line and curve from 22 to 23, which is one-fourth above the line, to N. Also curve arm-hole from 22 through R to H.

Draw the front line one-half inch inside at 21, curving outside one-half inch near V, coming back to line at U, and outside one-half inch at bottom to point 20.

From H, through L, draw line to 11.

Whatever the distance from 11 to 24 is place over from 11 to 13 and then curve from L, through 12, to 13. Sweep the bottom from 13 by a point 1 inch back of N and flatten this curve near 14.

Midway between R and V fix point 2, and midway between 2 and R point 1.

Measure the distance from the front at U to 10 and from 2 to C.

Deduct the half size of waist from this last and the remainder is taken out in darts.

From U to 12 is 2 inches.

From 12 to 9 is one-half of what is to be taken out in darts.

From 9 to 8 is always three-fourths of an inch.

From 8 to 7 is another dart.

Fix a point in the centre of the darts and draw a straight line from 1 and 2 to 6 and 5; and at right angles with waist-line draw lines from centre of dart down to the bottom. Now, one-third of the height under arm, down, fix point 3, and make 4 one-half inch more.

Draw the darts from 3 and 4 through the points, as shown, to 15 and 14.

FIG. 15. DOUBLE-BREASTED SACK JACKET.

[Illustration]

Draft by measure—breast, 36; waist, 24; and hip, 40. Length to waist 14½, and full length, 26.

By using these measures we will endeavor to show how to draft a jacket, each piece separately, thus doing away with the over-lapping of patterns as it occurs when it is drafted altogether, as in our previous articles on proportionate cutting. It is the same principle, but more practical, as a pattern can thus be cut whole in the skirt.

Commence by drawing the back construction line from O to L and O to P.

From O down is three-fourths inch to T.

From O to E is one-fourth of breast—9 inches.

From T measure down to the waist 14½ inches, and the full length to L, 26 inches, and from O over on top line to 5 two inches, and curve the top, T, to 5.

B is midway between O and E.

K is 6 inches below the waist; now draw all the lines across.

At F go in 1½ inch to back, and draw a curved line from the centre seam of the back, from T to 1½, and spring out three-fourths inch at 9, thence to L.

From E to 7 is one-third and one inch, equal to 7 inches. Draw a line up from 7 to 3, and one from 5 to 3.

Raise above 3 one-half inch to 4, then curve the shoulder-seam of the back; form also the curved line from 4 to 6.

Point 6 is midway between 3 and 7. Make the width of the back at waist 2 inches, and from 2 draw a straight line down to the bottom.

Now curve the side seam from 6 past 2 to 10 at bottom, which point is three-fourths of an inch outside of the straight line, also connect L and 10 by a line.

[Illustration: Fig. 15]

THE SIDE-BODY.

Cut out the back and lay it on the paper in such a manner that the breast-line will lay on the same line further towards the front, so that there will be sufficient room at the bottom to draft out the side-body whole. Now, first draw along the edge of the back from 6 to 2; go in at 2 one inch, and curve from the blade down to 13.

At 13 draw a straight line down, and curve out from 13 to 18; this last will be exactly underneath point 8 of the back, and from here to the bottom draw it with a slight curve to 20, which is the same length as point 10 of the back.

From 14 to 13 is 2 inches, and make the distance from 11 to 12 the same; now draw a straight line from 12 to 14, and down to the bottom.

Go out from 15 to 16 one inch, and curve seam from 14 to 19, which should not be over 1½ inch outside of straight line. Draw line from 20 to 19.

THE FRONT.

Lay the side-body on breast-line and back in position against side-body, so that the breast-line of each lays correct and straight, then measure from I on centre of the back to the centre of the front D, half-breast, or 18 inches; at this last point draw a line up and down for front line.

[Illustration]

Point 12 of the side-body will now be the same as point 21 of the front; draw down to 27 a line with a slight curve to shape in at waist; also draw a straight line down from 27 to 35 at bottom.

From P to C is one-sixth, or 3 inches, and the same to 23, now sweep the neck from P.

From C, which is one-half inch above the top line for erect or ordinary builds, on the line draw one to B on the back.

Now measure the length of shoulder on the back from 5 to 4, and place the same from C to 22, and curve a little above it, as shown in Fig. 15. From G on side-body forward to front of arm is one-fourth, or 4½ inches, where a line is drawn from H; then finish arm-hole from 22 to H and 21.

Finish the side-seam by going out at 31 1 inch to 33, and curve seam to 34; also locate the length by laying the side-body, point 12, on 21, and where 19 comes is 34.

From C, by 34, sweep the bottom of front and straighten this some in the centre.

At the centre of breast-line, beyond D, put one-half of breast, and curve the front line from 23 to waist at S, where it comes back to the straight line, and thence to the bottom at 30, where it is one-half inch outside of it. For a double-breasted jacket make the lap 2½ inches at breast, 2 at waist, and 2¼ at bottom. Whatever the size of the draft at waist, from points S to 1½ on back, exceeds the actual measure must be taken out in darts.

In this Figure we take out one dart only, starting in the centre, J, which is between H and D, and take out between points 25 and 26, the full amount which will be about 2½ or 3 inches, starting the dart at 24, two-thirds above 25, and finishing about 4 inches below the hip-line.

In case two darts are preferred they are put in as already shown in previous Figures.

FIG. 16. SACK JACKET.

This shows the manner of drafting a jacket with an extra piece under the arm and only one dart in the front. The correctness of the lines, and the simplicity of the process, will be of much benefit to our students. This method is the same as we have given in several different styles, and therefore it is drafted in a similar manner. It requires only one method to draft all kinds of garments, and our aim in giving the different shapes is to familiarize our readers with its application to a variety of shapes and styles, so that whatever garment they may be called to cut they will be able to do it.

[Illustration]

Let us take a size—36 breast, 24 waist, with a length of 30 inches, and a waist reaching down from neck 15½ inches.

In drafting, first draw the line O-F.

From O go down three-fourths inch for the top of the back.

From the top of the back to D is the length to the waist, 15½ inches; from the same point down to the bottom of the garment measure 30 inches to F.

At D go in to point 14 1½ inch. Then from the top of the back to 14 draw a straight line, and also draw one from 14 to F, curve slightly over the line below 14, past 20, to F. Make the width from 14 to 2 two inches, and run a line parallel with back-line from 2 to 29, and curve it a trifle, as shown on the Figure.

From O go down to C one-quarter of the breast, which is 9 inches, and draw a line across. Draw a line from O over to K at right angles with the back-line.

In the middle, between O and C, fix a point marked B and draw a line over to N. From C to G is one-third breast and 1 inch, equal to 7 inches, and draw a line at right angles with line C-G. From G to H is one-fourth breast, equal to 4½ inches, there draw a line at right angles with the one under arm.

From 1, centre of back, to J, at the front of the breast, place one-half of the breast-measure, equal to 18 inches, and at J draw a right angle line up and down like line K-J and S. From O to 13 is 2 inches.

From N to 13 draw a line, and then, commencing at 13, curve the shoulder, letting it rise above the last line one-half inch to 14.

Starting three-fourths inch inside of line G begin to curve the arm-hole past 12 to 17 and H. In the middle, between N and G, fix the point to start seams from for the back. Draw line from thence past 19 to 2 and 29—this makes the back with narrow shoulders.

To draw the first side-body place from 2 to 3 one inch, curve the line from 19 to 3, gradually beginning to separate below 19 without curving too much, care being taken to get a neat curve. Below 3 curve toward the back till at hip, 21, it will meet the back, and thence downwards, till at the bottom it will over-lap the back 1 inch to 30.

Make the width of side-body at the top any distance desired, say 3 inches, and make it the same at waist, or from 3 to 4, 3 inches. Then curve from 17 to 4.

Lay a long straight-edge, closing at 17, and three-fourths inch from point 4; while in this position mark a line along it from the hip-line downward, and connect it by a curve from 4 to 24.

Go in from 4 to 5 a distance of three-fourths inch, and curve from 17 to 5, but be careful to commence to separate side-body only 1½ inch below 17. Lay a straight-edge, as before, at 17, and three-fourths inch from 5, so that it will lay towards front, then from hip downwards draw a line to the bottom and finish by curving from 5 to meet this at hip, 23.

From 17 to 18 may be only 1½ or 2 inches, according to the size—2 inches will be sufficient for a 36 breast.

Draw a straight line to 6 and take out a slight curve to shape it to the form. Again, lay a straight-edge against 18, and three-fourths inch from 6, and mark along it from the hips downward; curve from 6 to hip.

Commencing at 18, curve the front to 7, taking out one-half inch, then lay a straight-edge against 18, and three-fourths inch from 7 mark along it below the hips and finish the curve from 7 to 25.

To produce the front, place from K to P one-sixth of breast, equal to 3 inches, also the same from K to 16. From P to B draw a line, then place the same distance as on the back shoulder from 13 to 24 on to P to produce point 15, or the length of front shoulder, curve it above this line, and at 15 drop it one-half inch below. At 15 curve the arm-hole to H, going outside of the line enough to give the arm-hole a good shape, but under no consideration go beyond point H—rather go inside.

Curve the front-line one-fourth inch inside of 16, and outside at J one-half inch, and coming back to R, where it should spring out to the bottom one-half inch at S.

Add beyond last curve 1 inch for the lap, on a single-breasted jacket, all the way down.

Measure from 14 to 2, 3 to 4, 5 to 6, and 7 to R, which will be about 15 inches; but as the waist must be 12 inches, or one-half of 24, we must take out the difference in a dart, which is 3 inches. Divide the space between H and J which gives point I, and from this draw a straight line down. Go down from I 2 inches to 17. On each side of the line at 9 place one-half of the dart, 1½ inch, then curve from 17 to 8, 27 and 35; also from the same point to 10, 28 and 36. At the bottom it should be three-fourths inch.

[Illustration: Fig. 16.]

The bottom of the first side-body must be one-half inch longer than the back; the second the same length as the first; and the front must start at the same length as the second, and curve forward 1 inch below line 33 to 37.

FIG. 17. SHORT JACKET.

This gives a short jacket, of a neat, peculiar shape. As regards the darts all points are the same as given in Fig. 18, except that instead of putting in two side-bodies we only cut a dart out under the arm, and one across the front, both being equal, of a size required to make the waist lay close. The dart in front is started from H and runs into the pocket.

[Illustration: Fig. 17.]

The back is made 4 inches wide at the waist and wide enough at the bottom to harmonize with it. Point F is the hip. Any sleeve cut to the size of arm-hole will go with this.

FIG. 18. JERSEY BLOUSE.

Draw line O-J and O-F. From O to D is one-fourth of breast. From O to 20 is three-fourths inch. From O to D take one-half the distance to get point B, and in the centre, between B and D, is point C. From 20 to E is length of back and to F the full length.

[Illustration: Fig. 18.]

Go in from E 1½ inch and draw the back-line from 20 to 1½ and to F. From O is 2 inches for top of back to 2. From D is one-third of breast and 1 inch to G. Draw a line up from G to 6. From 6 draw one to 2 and curve 1 inch above it at 1.

Curve arm-hole from 1 through 9 to 10. From G to H is one-fourth of breast—4½ inches on a 36 breast. Draw a line up. From back, near D, to K is one-half of breast. Draw line up and down. From J back to I is one-sixth of breast, and the same down to 3.

From I to 6 draw a line. Curve above line at 18 one-half inch for front shoulder, and curve the arm-hole from 18 to 17, and H to 10. Point 10 is about 1½ inch from G.

Make the width of back 5½ inches from 1½ and 9½ inches to point 10, and 10 inches at bottom. Then curve the side-seam at 10 to 5½ and U. From N, at front of the waist, go in 3 inches, to 16 4½ inches, and to 4 6 inches.

Draw a straight line up and down through 16, and form the dart, from 20, through 3 and 4, to 5 and 6.

Lay the back on the front to meet at 10, 5½ on V, 8 on U, to get the right curve for the side seam.

Measure the waist and make the distance at V to correspond with it. Using I as pivot sweep from 8 for the bottom of the front.

Add one-half inch button-stand, and 1 inch on the side the buttons are sewed on. Buttons should be 1 inch apart.

The Jersey is finished with standing collar.

This pattern is intended only for goods which are elastic—like stockinet or tweed.

The seams in the dart and at side should be stretched somewhat in pressing, thus allowing them to fit closer to the form.

FIG. 19. GIRL'S SACK.

[Illustration]

This is a sack for a young girl of size 31 breast, close-fitting. The figure illustrates a very jaunty and comfortable jacket.

For the Fall Season it should be made of heavy ribbed cloaking, of a dark shade of grey, and an extra neat finish is obtained by binding it with a braid of a darker shade, and buttons to match the braid.

It has eight buttons in front, is cut single-breasted, with a very small turn-over lapel, which allows it to be buttoned up close to the neck.

A side edge is imitated on the back by braid, and three buttons put on it.

The full-size pattern may be cut by following the Figure, as represented, using inches for every number marked out.

In order that this may be readily understood we will go over this manner of doing it again, so that our readers who desire to take them off may not make any mistakes.

First draw a line on the edge of paper, and draw out the back first, by fixing a point at the top.

O is the starting point. From O go down in inches as indicated by the points marked ¾, 2¾, 5¾, 13, 20 and 34.

Draw lines across from these points and apply the numbers on the Figure to these lines. When all these points are fixed connect the points by lines, which will form the outlines of the back.

For the side-body use the same process and you will have the full size. It can be made double-breasted by adding 1½ inch in front of the breast all the way down.

[Illustration: Fig. 19.]

FIG. 20. BRAIDED JACKET.

This Figure represents a fashionable style of close-fitting jackets for Spring wear. They are made single-breasted, having the buttons close together, and have the appearance of a Jersey. The same may be made double-breasted by the addition of 2 inches to the front. In trimming they may be plain, with nothing but small flat lasting, or a round crochet button. Braid in military style may be used, or a simple binding.

The Figure is drawn from a pattern of a 36 breast, 25 waist; the length may be regulated to taste. In drafting this pattern use inches for all the figures on the draft.

[Illustration: Fig. 20.]

FIG. 21. DOUBLE-BREASTED CUT-AWAY JACKET.

This gives an elegant and very stylish jacket. The front is double-breasted towards the top with a broad, sharp lap, while at the waist only one button is used.

In order to enlarge the draft to full size, which is a 36 inch breast-measure, use inches for all the figures on the draft.

The jacket itself is finished at the neck with a collar, which is put on to the cape. The front, at the neck, is held together by an agraffe ornament. This garment, as it should appear, may be seen by the illustration.

[Illustration: Fig. 21.]

FIG. 22. LADY'S JACKET.

These drafts illustrate a new style of lady's jacket, which will be acceptable to many for street wear. The style and general effect at once denote the character of the garment. The jacket is well adapted for outdoor wear. It is made with a moderate addition for double-breasted added on to the fore-part, and the button holes are worked in close together, as the buttons now used are so very small; therefore, on this jacket, they are placed only one inch apart.

The waist is medium length, and the skirt can be made to suit the height of the lady. A lap-over is made at the centre of the back skirt, finished off with small buttons put close together.

The pockets may be put in at the side like a coat pocket, or only a flap put on, leaving the top edge unfastened, which forms the opening. In the latter case it can be ornamented with buttons. Pockets, however, are only put in when it is cut longer than Figure.

The sleeves are narrow, finished by a row of buttons, and can be regulated in width by the measure of the arm. This is very essential, as ladies now-a-days like the sleeve as close as possible.

The darts are cut down to the bottom, which is more preferable to running them to a point, as a seam looks better which runs continuously to the bottom. Cutting the dart so that it reaches only to the hip, will, unless carefully made, rise up in a puff at its lower end. It must always be borne in mind that the spring must be allowed to rise at the side-seam. The sudden rise of a lady's hip, and the marked difference between the size of the waist and of the body but a few inches below, make it extremely difficult to obtain the necessary amount of freedom for the prominence of the figure at this part of the body.

The bottom edge of this jacket should be edged on the inside by a facing of silk, which is held on tight so that the edge may cling close to the dress-skirt.

The collar is cut like a coat-collar and the lapel rolls short. A narrow binding one-half inch wide is put on the edge on all goods with a close and firm texture, while on heavy, loose material, the stitching looks more appropriate.

[Illustration: Fig. 22.]

The button-holes run down to the bottom of the skirt. This form of jacket makes up well in fine diagonal or brocaded velvet.

For heavy winter wear, rough suiting will make very stylish garments.

The lower edge of this jacket may be drawn straight across instead of curving up over the hips as on the Figure, and then it is equally as well adapted to be worn with any dress, as in the shape we illustrate.

FIG. 23. SINGLE-BREASTED LONG SACK.

Figure 23 represents a long, close-fitting, single-breasted sack, consisting of back, side-body, front and sleeve. They are all drawn by measuring the lines, and placing the number of inches on each line as designated by the numbers shown on the Figure. Thus, for the back draw a straight line from O, then apply each measure as shown, and draw the lines across at right angles with the line O. When these figures are all located, finish by drawing the outlines.

Draw the straight line O down to the desired length for the side-body; at 28½ apply the figures on the lines—when these are all fixed curve the outlines.

For the front, draw the straight line down from O, and mark the number of inches for both length and width; when these are all fixed finish the outlines.

[Illustration: Fig. 23.]

The sleeve is drawn from O down to the required length, applying the number of inches for length as well as width, as shown; after these have all been found, and the line drawn at right angles with the line O, draw the outlines. After the upper part of the sleeve has been drawn cut it out; then locate the points for the under-sleeve, and lay the back of upper-sleeve against the points of the back part of the under-sleeve, and draw it like the back of upper-sleeve; fix the points in front, and lay the upper-sleeve on and draw for the front of sleeve, then finish for top, as shown.

FIG. 24. JACKET OR CLOAK—FROM A WAIST PATTERN.

The method which is explained below is one of the most handy, as well as the easiest, that can be used, and will invariably produce good results. It is evident, in the first place, that the original pattern must have the essential qualities of fit and good lines, otherwise it would be of little value as a base or guide to produce another garment. In order to get such a waist pattern one must be able to design it, or have it on hand; in the latter case we are prepared to furnish these patterns when ordered.

THE BACK:

In drafting a jacket pattern, first draw a line (like O-G) on the edge of your paper. Lay the back against the line at O and within 1½ inch of the line at the waist, then trace along the centre seam from O to 5. Now move it one-fourth inch away, this is for seam; then the same quantity is allowed above at neck from 1 to 2 and from 2 to 3.

Along the arm-hole, from 3 to 4, trace close to the pattern. Measure next the length wanted from O to 5 and 9 and draw a line over to 10. From 5 to 9 draw a straight line, and then curve outside of this, at point 8, about one-half inch, as shown on Figure.

Make the width of waist any size desired, say 3 inches, which establishes point 7, and from this point draw a line down to 10. This line should be no further away from the first line at 10 than at 7, or the distance from the line 9 to 10 should be the same as at waist, from 1½ to 7. Now, starting at 4, slightly curve to 7 and go one-half inch outside of straight line to 10.

THE SIDE-BODY.

In this case, as on the back, the first thing we do is to draw a straight line from O to 10. Now lay the side-body against it, at O, and swing it away from the line at the waist 1¼ inch. Trace along the pattern from O to 1¼. Then move the pattern one-fourth inch away from the last line, which would leave from 1 to 3 just one-fourth inch for the seam. From 5 to 6 go in one-half the distance allowed over and above the allowance on the back, as from 6 to 7. Now curve the side-body from 2 to 5, keeping as nearly as possible the same shape as the original. Then from 5 draw a line down parallel with the first line which runs from O to 10. Now apply the back from 2 to 9 and regulate the length, which is point 9; then from 5 curve one-half inch outside of straight line at 8 to 9. At 9, square across to 10, and also draw a straight line from 1¼ to 10, and begin to curve from 3, past 7, to 10. This curve should be more round near hip, or begin to curve closer to the waist. The curves on the back and on the side seam, from 5 to 8, may be gradual, as it thus has the appearance of being longer waisted than it actually is.

THE FRONT.

[Illustration: Fig. 24.]

First draw the straight line like O-B. Lay the fore-part of the pattern against this line, touching at the centre of the breast, B, and trace along it at the front from 1 to the bottom at 3. Next move the pattern back one-half inch to B. Trace along the arm-hole without any allowances, but on the top of shoulder add one-fourth inch, also a trifle at neck. On the side-seam, from 15 to 20, add one-fourth inch; then lay the finished side-body on top of the front, touching point 15, and at the waist at 20, and finish the balance from 20 to 22 by the side-body. Now from the top of the shoulder-point, by the bottom, point 22, sweep the bottom to the front at B. From 3 to B draw a straight line, and for a double-breasted jacket, as the Figure given, add on to the front, at B, 3 inches, at waist 2½ inches, at the bottom 3 inches, and shape it as shown. At the bottom, after it has been curved by a sweep, straighten it one-half inch above the sweep in the centre. Instead of two darts at the back only one is used, as shown, and this one can be increased one-half inch, and a cut is also taken out under the arm from 16 to 17.

It is evident that two darts can be put in as well as one, or when the same is intended for plush goods the darts can be left out altogether without altering the balance in any manner.

To produce a collar for this jacket draw a line from C, where it is intended to roll, to E, which is one-half inch from curved line of neck; then drop down from this line at 13 to 11 one inch and curve the break, as shown from 11 to E. From 11 to 12 is ¾ inch; curve this also to neckline at F, and thence along the neck to the front. From 11 to 13 make the part of collar which is to turn over 1½ to 2 inches wide, and shape to the front at G.

Sleeves for this jacket are cut similar to those already explained.

FIGS. 25 AND 26. WALKING COAT.

[Illustration: Fig. 25.]

By using a sack pattern, cut to the measure, a walking-coat can be cut in the most ready manner.

The back is the same as a sack-jacket. We only measure from the top down to the length of open skirt A. From here add the lap for pleats; single pleats require only 1¼ inch; box pleats, according to size, 2 to 4 inches.

The side-body is cut off at a length to correspond to 2 on back, plus one-half inch, and curved up some towards side seam.

The front is made as long as the side-body, and the bottom swept from the shoulder-point. When cut it will leave the skirt in pieces as 1, 2, 3 and 4.

Now take these pieces and lay them down, closing at hip, so that the opening will be no more at bottom than at top; they lay close together at 12, 13 and 14.

Now draw along the skirt at back from 4 to 15. From 4 draw towards 5, raise one-half inch above the pattern to 10, curving pattern at front.

Put in a dart at 7. From 11 to 16 trace along the front, and also along the bottom. Add the pleat behind.

The side-body in this Figure is laid in a closing position at side, point 2, to show that the seam must have a continuous curve from 1 and 2 to the front.

The distance from 1 and 2 to 3, and from there to the front, is noted, and the skirt from 4 to 5-7 and 11 should be just the same with 1 inch more added, which is pressed in before the skirt is seamed on to the fore-part. It will be noticed that in laying the pieces of the of the skirt together they close at 14, 12 and 13, but at the top and bottom they are separated, equal distances, the cut at 7 reduces one opening, and 1 inch fullness equalizes the amount the fullness is greater at 9 and forward. The addition for single and double-breasted is made by adding on in front of the fore-part and also on to the skirt: for a single-breasted 1 inch is enough, but for a double-breasted from 2 to 3 inches is required.

[Illustration: Fig. 26.]

FIG. 27. DOUBLE-BREASTED NEWMARKET JACKET.

[Illustration: Fig. 27.]

Commence this by drafting on the same principle as all drafts—by the Proportionate System—by drawing line from O to F. From O go down to 11 three-fourths of an inch, and to 10 2 inches; from 11 to 10 curve the top of the back, and measure from the top of the back, at 11, to C, the length of waist 15 inches, to D 18 inches and to F the full length, 32 inches; at C, O and F draw right angle lines across. From C to the back is 1½ inch; Draw a line from 11 to 1½, and one from 1½ to F; make the width of back from 1½ to 2 inches wide. From O to B is one-fourth of the breast-measure, 9 inches in a 36 inch breast, and A is midway between these two points; draw lines over from A and B. From B to G is one-third of breast and 1 inch, equal to 7 inches; from G to H is one-fourth of breast, or 4½ inches. From Y to J is one-half of breast, 18 inches; draw lines up from G, H and J, also down from J to N.

Where line A crosses line G, at M, draw another line from M to 10; raise one-half inch above M to V, and draw a curved line from 10 to V.

Commence to curve the arm-hole from V to M and H, dropping one-fourth inch below breast-line at 15.

In the centre, between M and G, begin to draw the back to 2 at waist, and from there, with a slight curve, to Z at the bottom, so that the distance from F to Z will be about equal to that from C to 2.

Go in from 2 to 3 one inch and shape the side-body from line under the arm to 3 and S, where it touches the back; make the side-body any width desired, say 2 inches to 14, the same from 3 to 4, curve the seam under the arm and spring it out below 4 to 21, to give it ease over the hips; also draw the curve for the piece under the arm from 14 to 4 and 20. From S curve up to 21, which latter point is 1½ inch above the line S-18. Point 20 is on the same level as 21, the line runs straight across to the front seam which runs down from 5. The piece under the arm is 1½ inch wide at top, from 14 to 15, and 2 inches from 4 to 5; this should be shaped somewhat like draft.

From L to I is one-sixth of the breast, 3 inches, and the same down from L to T. Curve the neck; from I to A draw a straight line, and place the length of shoulder from 10 to V on the front from I to U; shape the front of shoulder by dropping below line at U one-half inch, and raise slightly above it at 12.

Finish drawing the arm-hole from U to H, going out beyond the line H at 13 about one half inch.

Draw from T, at the front, outside of J one-half inch, thence to K at waist, going inside of front line one-fourth inch at K and N to point P at bottom.

In the middle, between J and H, locate a point for the dart, and in the centre, between this and H, fix another point for the back dart. From K to 1½, across the waist, measure the distance, taking out 1 inch between 2 and 3, which will be 16 inches; deduct the size of waist, 12 inches, from 16 inches and the remainder, 4 inches, is to be taken out in darts; therefore, put in two darts of 2 inches each. From K to 9 is 2 inches; from 9 to 8 is one dart; from 8 to 7, between the darts, is three-fourths inch; from 7 to 6 is another dart of 2 inches. About 2½ inches below the waist-line begin to draw the darts past 9, 8, 7 and 6, nearly straight down from waist-line. From 21 curve lower seam to 19, 18 and N; at N it is one-half inch below straight line.

Make the lapel straight on its inside edge, and 2 inches at waist, and 3 inches at centre of breast, in width, and shape like Figure.

To draw the skirt lay a straight-edge from 3 to S against the side-body, and draw a line to R, then curve it about one-half inch more over the hips. Regulate the length by the back. From S draw the upper edge of the skirt to within one-half inch of side-body at 21, thence to N; from N forward add the width of lapel and draw straight down; also put in two cuts on the hip, of one-half inch each, and the skirt will be right to fit the body. Should it, on measuring, be a little too wide, take the extra width off in front; whatever overlaps on the side-body will equalize the loss of the darts.

A flap can be put on over the hips. An ordinary coat-collar will suit this jacket.

FIG. 28. TRAVELING ULSTER.

[Illustration: Fig. 28.]

A Spring and Fall garment for traveling or outdoor wear is represented by this Figure and is a reduced copy of the pattern of a 38 size breast, and can be readily enlarged by simply using inches for the numbers marked upon it. The draft is a close-fitting traveling paletot, double-breasted, and buttons down to the bottom, and has a collar which turns over, as represented by Fig. 5. This collar should be well stretched with the hot iron, at the lower edge, before it is sewed on, in order that it may cling around the neck nicely. This way of making and sewing on a collar is far superior to the usual custom of dressmakers, and is always adopted by tailors in making jackets or other ladies' garments.

The back has at its centre, below the waist, a lap, which can be put in a box-pleat or lapped over like a coat, and at the side it has a simple pleat.

The front has a large dart cut in one piece—that is, like a sack coat, having the skirt attached to the body—but the side-body is sewed in as cut, in a separate piece. Over the hips pockets are put in covered with liberal flaps.

For use as a traveling garment it will be well to make it out of waterproof cloth, but it makes a handsome street paletot when made out of diagonal cloth or melton.

FIGS. 29 AND 30. NEWMARKET.

[Illustration: Fig. 29.]

This style of Newmarket has only one dart. Proceed to make a full size draft in accordance with the directions. First draw a straight line O, and mark off the number of inches down from O, as given on the Figure; at these points draw lines across, and on these lines mark the number of inches as given, in like manner proceed to draw each part of the garment.

[Illustration: Fig. 30.]

FIG. 31. RIDING-HABIT.

[Illustration: Fig. 31.]

The demand and orders for these garments have, so far, been considerable in the leading houses, and a few hints are always seasonable, not only to those who make them for the highest fashionables, but especially to those who are located in smaller towns and who are not often called upon to make this style of garment. There are now many ladies who have a horse at their disposal, and whose chief enjoyment is in equestrian exercise, and it is quite necessary, not only for the tailor but the dressmaker, to know how a riding-habit should be cut and made. At one time it was thought impossible for anyone but a tailor to make a stylish riding-habit, but now many ladies have them made by their dressmakers.

[Illustration]

The first thing necessary is a good measure of the form, by which a correct pattern must be cut, as a well-setting, comfortable riding-habit cannot be made without it.

The jacket has a few peculiarities:

There should be no seam down the middle of the back; the front, side-body and back are cut one inch below the natural waist.

The skirt and back form a pleat like the skirt-pleat of a coat.

The buttons should be small and round. The sleeves are tightly buttoned up at wrist.

The inside of jacket should be lined with silk, carefully wadded and stitched in close rows. It should have a belt inside, stitched to each seam at waist, which is to close it tight to the form.

The Figures we give show to advantage some of these peculiarities. The draft is a good model of such a habit, and is universally adopted, being both suitable and elegant. It “looks quite English” and very pretty. A plain standing collar of white linen should be worn with it and a gentleman’s cravat of black silk, or if the jacket is made with the lapels turning down a flat scarf is more appropriate.

[Illustration]

We add to this an article published in “Munster’s Gazette of Fashion” on riding-habits. This will enable our readers to be more fully posted, not only on what is worn here but what is in keeping with London styles:

“We have devoted one of the plates issued with the current number of our publication to the representation of the newest and most fashionable style of a lady’s riding-habit in wear. The lengthening of the waist, which we reported last year, has been maintained, although it has not been increased; and the jacket-skirt is about the same in length. It is fastened up to the throat by buttons and holes, and with a small stand-collar rounded off at the front. The jacket-skirt is cut in one piece instead of two, as heretofore, and at front runs off at an angle from the bottom of the front edge of the fore-part, and is lined with cloth, or interlined with some article of substance, to give it a firmness. The edges of the back skirts terminate in a point at the bottom. A small square tab, with two holes in it, is sewn across under the bottom of the back, and is fastened on to two buttons sewn on the top of the back part of train. The edges are usually trimmed with a narrow silk braid, sewn on flat, and the body and the sleeves lined with light colored silk. Ball buttons and fancy silk buttons are generally used. Five or six buttons are sewn on at the hind-arm; the two lower holes only are worked open.

Some ladies affect a certain tone of severity in their riding-habits, and eschewing all fictitious aids by way of adornment to the bodies have made them perfectly plain, with the edges turned in and stitched, and smoked pearl or vegetable ivory shank buttons.

Veils are no longer considered correct, no doubt because they may be considered too effeminate in character and out of place with the “billy-cock” hat.

The train, as now worn, is only cut a few inches longer than the walking length. It is turned up at the bottom, with a narrow hem only, and the V's taken out at the seams are covered with ribbon.

Colored habits are being worn in rich shades of brown, olive and green—not too light. Blue and black are also worn. The small diagonal elastic coating and Venetian cloth are preferred on account of their making up so satisfactorily. Dress meltons and tweeds are also worn, but the makes are not so appropriate.

One inevitable consequence of short and scanty trains is the necessity for every lady, taking equestrian exercise, to wear riding trousers. They are usually made of the same cloth as the habit, with a fly-front open to leg-seam, or with a long opening at each side-seam and a button and button-hole in the centre, and a narrow strap at bottom."

In order to produce Figure 31 use inches for all numbers on the draft. But in drafting it to measure use the same principle as laid down for waists, and lengthen the skirt as on Figure 7 and draw the skirt like that on last Figure.

FIG. 32. CIRCULAR.

Draw lines O-5 and O-J. From O to J is one-fourth of breast. From O to H is one-third of breast. Lay the pattern of the back against H and 1½ inch inside of line at the waist. Lay also the pattern of the front against the shoulder of the back near F and touching front-line at J. Draw along the top of the back from H to 1, and add to the pattern at 1, for seams, one-half inch. Draw from 1 to F and from 2, on the front shoulder, to F. From J, along the front of the body-pattern, draw a straight line to 4. Now from 1 and 2 draw a line and make a point in the centre at 3. Apply the length from H to 5 for full length of what the garment should be, and using point 3 as a pivot sweep from 5 to the front for the lower or bottom edge; then square the bottom at 5, and in front at 4, as shown in the Figure.

[Illustration: Fig. 32.]

If a seam is wanted draw a line through the centre from F and take out about 3 inches at bottom, starting from 6 to 7 and 6 to 8.

For a close back, curve from H along the back to 1½ and thence to 5 at bottom.

FIGS. 33 AND 34. RUSSIAN CIRCULAR.

In making a pattern of this garment we first draw a line on the edge of paper and make a point on the right end, as O. From O down place three-fourths of an inch. From O to I is one-half of breast measure, or 9 inches, for a 36 size. Between O and I is J. H and I are at right angles with first back-line. From I over on the line place one-third of breast, equal to 6 inches, and add 1 inch, making in all 7 inches, and draw a line up to 5. Next, from O on top line place 2 or 2½ inches and curve from ¾ to 2½.

[Illustration: Fig. 33.]

Measure down from ¾ to D, the length of waist, say 15 inches, and the whole length to R. Go in from straight line at D 1½ inch and curve the right back-seam from ¾ to 1½ and R.

Make the back, at waist, 4 inches wide and curve from 5 through waist at 11 to 12 at bottom. The run of this line should be nearly straight past V and curving at 11, and should also be wider at bottom, about 1 inch more than from D to 11. From 2½ draw a line raising it one-half inch at 5.

For the front (Figure 34) draw a straight line from O to J. From O down to a is one-eighth of breast, equal to 2¼ inches. From O to B is one-sixth of breast, or 3 inches. From O to K is one-fourth of breast, or 9 inches. Square lines across at all these points. From O to A, the neck, is one-sixth of breast.

Lay the back on to the point A and extreme shoulder resting on the line at C. Now draw along the back shoulder while it is in this position, and also curve from C to 12, which should only be 4 inches below C.

From K go out to H one-quarter of the breast, less 1 inch, equal to 8 inches. Having established this we can curve the shoulder easier, as seen by dotted lines. Measure from K over on the line one-half of breast, equal to 18 inches, and one-third of breast, or 6 inches, added.

Now lay the back-line against this last point in such a way that point 5 of the back will rest on line A-13, and so that it will be placed as seen in Figure 35. Then carefully measure to see if the distance from K-H and to the back-line will be exactly one-halt and one-third of breast, or 27 inches. Then curve from 12 to 13 to 14 down the back and reducing it at the bottom about 4 inches from the position as it would be when the back is laid as stated.

Now by the length of the back regulate that of the front, and then sweep by the point of shoulder A from 10 to J. This latter point, and part of this round, as produced by the sweep, should be shortened about 1 inch. Curve the neck from A to B, and add 1 inch all along the front for a turn-in hem.

From where the back lies against the wing, at O, draw the curve to 13 on the top of sleeve head.

The upper part of the sleeve-head should be gathered-in considerable, and at O a notch should be placed to facilitate the sewing in, for notch should be sewn on notch. (See Figure 35.)

[Illustration: Fig. 34.]

FIG. 35. CLOSED CIRCULAR.

After this has been drawn the same as the Russian circular, lay it against the front and cut without a seam from O down to the bottom. For this shape, after the shoulders are seamed up, gather in the round of sleeve from O forward. The same can be cut like the circular; also cut off in front from top, past V, to the bottom, in a straight line down from B. This makes a wrap with a back wing and a front. When cut in this manner an opening can be left for the hands to go through, as shown on the Figure, below E.

[Illustration: Fig. 35.]

A short cape, such as have been worn for some time in Europe, and are just making their appearance here, is cut like this, reaching, however, only to the waist. This same wrap can be cut from a dolman pattern by laying the sleeve of a dolman on to front so that the front notches come together and the two patterns close together some distance above, or till within 4 or 5 inches of the top of the shoulder, then draw along sleeve-top past the back of the sleeve.

If a line is drawn through the shoulder-point, next to the sleeve, at right angles with the front, and the back shoulder-point laid on this line and closing against the sleeve at blade, it will represent exactly this circular cape, and will be one of the easiest ways to make it. The Figure shows the outline of the dolman sleeve by the dotted line from E forward, as it appears when lying in position.

These several wraps can be made of silk, and fur-lined, or they may be of brocade, velvet, or seal, and are handsome in shape and outline when correctly cut. As they are so different from the old circular they will be much sought after, because of the newness of design and that the sleeve can be raised on the shoulder to harmonize with the increased prevalence of gathered and high style of sleeve-heads.

[Illustration]

[Illustration]

FIGS. 36, 37, 38, 39, 40. DOLMAN.

Draw a line O-H; from O, down, mark three-fourths of an inch. From O draw a short line over to 3, and make it 2½ inches. From O down to B is one-fourth of breast, equal to 9 inches on a 36 breast. Point F is in the centre, between O and B; from ¾ to D is the length of the waist, and to H the full length of garment. Draw lines across at F, B and D. Between F and B, directly in the centre, make a mark C, and draw a line across.

Go in at the waist 1■ inch from line at D; draw line from ¾ to 1½ for the centre of back, and curve below D to H. From 1½, at waist, measure in to 4 3½ inches to 4 inches.

On line C make the width of back one-third of breast and one inch and draw a line up.

On the top of shoulder draw a line from 3 to 14, and raise it one-half inch above 14; commencing there, exactly at the crossing of the lines, begin to curve past 16 and 4 to 1 at bottom. Having finished the back, first make a line across in the middle, between ¾ and F, from E over; next lay a sleeve pattern, of regular size, on 15 as when sewn in the arm-hole; holding it at 15, swing it down till the upper part of the sleeve-head rests about one-half inch below line E, at 13, and when in this position draw along the round of

the sleeve, which will give exactly the round as shown on the Figure from 15, past 13, to 2.

[Illustration: Fig. 36.]

Next, placing the width over from B on the back line, measure to 10, 24 inches, and curve the sleeve from 2 to 10, running below the line 2 inches. Point G is about 12 inches below the waist, and from this place 1 inch more than one-quarter of the hips to 8, and draw from 6, which is one-quarter of hip from D, a line through 8 to 9; then finish the curve at bottom, and shape the round of front of sleeve to any desired shape. The front is constructed by drawing a line from O down the front edge or centre of front.

[Illustration: Fig. 37.]

[Illustration: Fig. 38.]

From O over to shoulder point is one-sixth breast, the same down to 3; also go down one-eighth breast and draw a line across; curve the neck from ■ to 3, and apply the same width of shoulder as the back on the front, ■ to 10. From O down is one-half breast to E, there draw a line over to 8 and make last point, from E, one-fourth breast less 1 inch.

Measure the distance on the back, from B to H, and place it from E to P, then sweep the bottom of the front by the shoulder-point, which gives line P to K. Make the distance over from H to J one-quarter of the hips, and 1 to 1½, inch more; draw a line from K through J to L. Next measure the back from 6 to 9 and place the same from K up to L; curve arm-hole from 10 through 8 to L. Add 3 inches for a lap of double-breasted style; mark and space the buttons.

[Illustration]

The under-sleeve is cut like the upper part from 2 to 10 and 11, like the outside curve. The inside curve from 2 to 7 is short, just as much as is needed to sew in the front—to find how much this should be we make a notch opposite 14 and one at 2, which is about 10 inches from 14. This measure, less 1 inch, is marked from 10 to 16, and at that point make another notch. What is left from 16 to L must be placed from 2 to 7, and this curve should be like curve on front. Lastly, draw a line from 7 to the star, which finishes the whole garment.

In order to draft a dolman pattern which will fit well and hang with a good balance the same manner of drafting as that which produces a good shaped sack should be used, then the balance and hang of the garment will be equally as good as in a tight-fitting sack, and a dolman can then be cut as close as a sack, if so desired.

The manner of drafting the back, side-body and front, are, in fact, just like a sack, the main difference being in the shape of the sleeve. The sleeve, even in the upper part, must be like an ordinary coat-sleeve, while the lower part may be any of the various shapes in fashion.

In drafting make a line to start on from O to F (Figure 37); from O down is three-fourths inch, and from O over to top line is 2¼ inches to 1. From O to B is one-fourth of breast, 9 inches of a 36 size. Point D is in the middle, between O and B, and point 6 is in the middle, between O and D. From ¾, which is the top of the back, measure down to C 15 inches, and to F 40 inches, the full length. Point E is 6 inches, or one-third of breast, below the waist-line at C. At all these points draw lines across. From B to H is one-third and 1 inch, equal, on 36 breast, to 7 inches; draw a line up to J; in the middle, between I, the point where the two lines cross and H, mark point K. At the waist-line go in from straight line C to 3 one and one-half inches, then draw line down from ¾ to 3 and from 3 to F. Also draw a straight line at right angles with waist-line from 3 to 6 at bottom.

Make the width at waist, from 3 to 4, about 3 inches, and draw also a line down to 7. Now curve back-seam, as shown, and whatever amount there is from 6 to F place from 7 to 8, and curve from 4 past 5 to 8.

Draw a line from I to 1, raise above I to J three-fourths inch, and curve the shoulder. Starting from J up upright line, curve back seam to 4 and 8; also mark a dim line from J past I, K to G, just like in a sack back—the dotted line shows that. Point G is one-fourth of breast, or 9 inches, from B.

Notice that the curve on the back, from C to 3, is a trifle outside of the straight line, and that below 3 it runs a shade inside to give an appearance of a long waist, and below E it curves outside again to F.

[Illustration: Fig. 39.]

The inside seam from J past breast-line should be very nearly straight, and begin to curve only near the waist, and from 5 down it must have the same curve as outside line below point E to F.

Now have a sleeve cut for a 36 size and lay this on to K, as shown, so that the sleeve-head rests against the line from K to I; then in the centre, between I and K, find point 2 and stick a pin.

Now turn to Figure 38: In the middle, between line A and D, draw line E; keeping it pinned at 2, move the lower part of the sleeve towards the back till the top of the sleeve-head just touches line E at 10. While it lays thus draw along the top from 2 to 10 and 9, also down from 9, in front of sleeve pattern, to line B. This gives the outline of the sleeve, but we modify it by drawing a corrected line from 10, inside of point 9 of sleeve, down to 12.

[Illustration]

Figure 39 gives the balance of the sleeve. First draw a line in the centre, between lines B and C, which places line D.

Then take out the pin which was placed in the sleeve at point 2, and without moving the sleeve stick a pin at point U; this point is found two-thirds of the width of the sleeve forward. When this is done take hold of the sleeve at its lower point and move it upwards, till point T of sleeve rests on line D at N, and then curve from 16 to N. To produce this curve just right take the distance from line B at 18 to line D at 17, and place the same from 17 to 19, and draw a straight line from 19 to 18, then curve line from 16, resting on line at 20, thence to N. From N curve form of sleeve to 21 and 15, and to 13 for one style of sleeve, or from U to 21 and 14 for another style.

Go in from 4 to 5 three-quarters of an inch; curve from 10, past 2, touching the back, and along it past line B, and thence separate from the back to 5 and 14—this last line must touch at point 13 on the straight line which was drawn down from point 4 on Fig. 37 and is marked 5 on the same.

THE FRONT—FIG. 40.

Lay the back down on paper and extend all the lines across, line A, B, C, D and bottom line. Measure from Z to A on line B, one-half of breast, or 18 inches; from B to H is one-third of breast and 1 inch; H to P is one-fourth of breast, equal to 4½ inches. Draw a line up at P, and one up and down at A. Mark line A also. From K to L is one-sixth of breast, equal to 3 inches, and K to 7 is the same, 3 inches; curve neck.

Draw a line from L to D and place the width of the top of shoulder on the back from L to 8, and curve from 8 upwards above the line one-fourth inch; draw from 8 down in front of line P to 9. This will be three-fourths inch in front of line P. Let this curve of the arm-hole extend below line B, or nearly down to midway between lines B and C, and curve to 6. From 6 draw down to 5, which is three-fourths inch from 4 to 15 and 17; at the last point it should be about 1¼ inch over the straight line drawn down from 4 on the back.

From point G, which, as before stated, is one-fourth of the breast-measure, 9 inches from B, draw a straight line down. Curve from G to 12, 13 and 18; the last point is 2 inches from T; also curve from G to 12, 14 and 19. Point 19 is the same distance from T as 18.

Draw bottom line from 19 to 30 at front, where curve three-fourths inch below the line. Add in front over F line, for double-breasted 3 inches, and for single-breasted 1½ inches.

[Illustration: Fig. 40.]

Now we have only to show how the under-sleeve is produced. This is done by measuring first the sleeve-head from O, where point J of the back is sewn on, to 16, which point is in middle, between 9 and 18. This will measure 10½ inches; as we put in 1 inch of fullness in the sleeve-head it leaves us only 9½ inches, which is measured down the front from 8 to 10 and notched. Lay sleeve notch, marked 16, on to notch on the fore-part 10, hold it there with a pin, move it till line on sleeve, marked C, will lay parallel with any of the lines, as C or B on fore-part. Then mark on the fore-part along the sleeve, from notch at 10 to N of sleeve, and from N to 21; the sleeve will now be marked on the fore-part line 10 to O, P and A, and will be cut the same shape as the arm-hole from 10 to A, and can be traced off on another sheet of paper.

The principle as given in this article is suitable, and the only thing necessary, to produce any style of dolman. The change necessary for the short or long pointed sleeve, or for any shape of arm-wing, does not alter the principle. Pleated backs, or very much fullness in the top of the sleeve, must be met by putting enough extra goods in to meet the amount required for pleats or fullness.

When a regular pattern is cut addition is made where pleats are wanted. When more fullness is wanted in the sleeve the easiest and most correct plan is to cut the sleeve in two, from the highest part of the sleeve-head, and opened as far as required, about 1 or 2 inches, and a little more round put on the top.

The principle, as shown in this book, will produce for every style of garment a correct fit, and yet it may be urged upon all using it, that in order to produce new styles, or garments of such styles that contain pleats or ornaments laid on the cloth, the reader's own judgment must necessarily help to carry him through.

In conclusion, let me say—that any point or measuring that does not seem clear, by addressing me I will always be ready to enlighten to the best of my ability.

PLATE DLIII.

LOBELIA ASSURGENS.

Assurgent Lobelia.

CLASS V. ORDER I.

PENTANDRIA MONOGYNIA. Five Chives. One Pointal.

GENERIC CHARACTER.

CALYX quinquefidus, Corolla monopetala, irregularis. Antheræ cohærentes. Capsula infera, 2-seu 3-locularis.

EMPALEMENT five-cleft. Blossom of one petal, irregular. Anthers cohering. Seed-vessel below, with 2 or 3 partitions.

SPECIFIC CHARACTER.

LOBELIA foliis lanceolatis serratis, infernè denticulatis decurrentibus, racemis compositis terminalibus.

LOBELIA with leaves lance-shaped, serrate, toothed towards the base, and running down the stem; the racemes compound and terminal.

REFERENCE TO THE PLATE.

1. A blossom spread open. 2. The chives spread open. 3. The seed-bud and pointal.

* * * * *

This curious species of Lobelia is a native of high mountains in Jamaica, where Brown informs us it grows to the height of 5 or 6 feet. The plant is at present so scarce as not to be enumerated in the Catalogue of the Cambridge Garden; nor has any figure of it, to our knowledge, been before published. Specimens were communicated by A. B. Lambert, esq. from his stove at Boyton, where

he informs us that the plant is now about five feet high, with some of the lower leaves a foot and a half long; that it began to blossom in the middle of July, and continued to the end of November; four or five racemes flowering at the same time, and nodding in the manner of ostrich plumes; the blossoms gradually opening in succession towards the top, and the racemes continuing to lengthen until more than a foot long. The flowers have withered without producing any seed. The plant appears to be perennial.

[Illustration: [Plate 553]]

PLATE DLIV.

VOLKAMERIA ANGUSTIFOLIA.

Narrow-leaved Volkameria.

CLASS XIV. ORDER II.

DIDYNAMIA ANGIOSPERMIA. Two Chives longer. Seeds covered.

GENERIC CHARACTER.

CALYX quinquefidus: Corollæ laciniis secundis. Drupa 2-locularis. Semina 4, seu abortu tantum 2.

EMPALEMENT five-cleft. Blossom with the divisions pointing one way. Berry 2-celled. Seeds 4, or from abortion only 2.

SPECIFIC CHARACTER.

VOLKAMERIA fruticosa glaberrima, foliis oblongo-lanceolatis integerrimis, pedunculis trichotomis axillaribus et terminalibus.

VOLKAMERIA shrubby and very smooth, with oblong-lanced very entire leaves, and peduncles divided by threes, both axillary and terminal.

REFERENCE TO THE PLATE.

1. The empalement. 2. A blossom spread open, one tip detached and magnified. 3. Seed-bud and pointal, summit magnified. 4. The seed-bud magnified.

* * * * *

Volkameria angustifolia is a dwarf branchy shrub flowering in great profusion about the middle of August. The blossoms are white and remarkably sweet-scented. It was communicated by Mr. Donn, Curator of the Cambridge Botanic garden, and is to be enumerated in the new edition of his Catalogue now in the press. It requires to be kept in the bark-bed in the hot-house, and is supposed to be a native of the Isle of France. We believe no other figure of it has been given.

[Illustration: [Plate 554]]

PLATE DLV.

ZINGIBER CLIFFORDIÆ.

Cliffordian Zingiber.

CLASS I. ORDER I.

MONANDRIA MONOGYNIA. One Chive. One Pointal.

GENERIC CHARACTER.

CALYX monophyllus. Corolla 4-5-fida. Antheræ 2. Filamentum simplex ultra antheras productum.

EMPALEMENT of one leaf. Blossom either 4-or 5-cleft. Anthers two. Filament simple, extended beyond the anthers.

SPECIFIC CHARACTER.

ZINGIBER scapo simplicissimo, crasso, brevi, capitulo subovato, bracteis inferioribus lato-ovatis obtusis; corollâ 4-fidâ, laciniis tribus exterioribus oblongis marginibus involutis; alteris sub-cordatis duplo majoribus, mox convolutis.

GINGER with an unbranched, thick, short flower-stalk, the lower flower-scales broadly-oval and blunt: the blossom 4-cleft, the three outer divisions oblong with their margins turned inwards, the inner inversely nearly heart-shaped and doubly larger, soon folding together.

REFERENCE TO THE PLATE.

1. Sheath at the base of the calyx. 2. A detached flower. 3. Seed-bud, anthers, and pointal, summit magnified. 4. The plant in miniature.

* * * * *

This fine species of Ginger, we are informed, is a native of Guinea, and in the gardens has long been supposed to be the plant which produced the Grains of Paradise, Amomum Granum Paradisi of Linnæus; but it certainly by no means accords with the character of that plant, either as given in the Hortus Kewensis or by Linnæus himself. From the other species of Zingiber enumerated in the eighth volume of the Linnæan Society's Transactions it is easily distinguished. Having as yet only blossomed in England in the collection of Lady de Clifford at Paddington, in honour of that patroness and lover of botany we have given its specific designation. The culture is the same as for other plants of the family. Our drawing was taken in 1804.

[Illustration: [Plate 555]]

PLATE DLVI.

PANCRATIUM AMŒNUM.

Broad-leaved Pancratium.

CLASS VI. ORDER I.

HEXANDRIA MONOGYNIA. Six Chives. One Pointal.

ESSENTIAL GENERIC CHARACTER.

PETALA 6. Nectarium 12-fidum. Stamina nectario imposita.

PETALS 6. Honey-cup 12-cleft. Stamens seated on the nectary.

SPECIFIC CHARACTER.

PANCRATIUM spathâ multiflorâ, fragrantissimâ: foliis longo-lanceolatis, corollæ laciniis tubum excedentibus: nectario 6-lobato, sinubus sub-denticulatis. _Willd. Sp._

PANCRATIUM with the sheath many-flowered, and very sweet-scented: the leaves long-lanced, the divisions of the blossom longer than its tube: and the nectary 6-lobed, mostly with little teeth between.

REFERENCE TO THE PLATE.

1. A flower spread open.

* * * * *

Several species of the genus Pancratium approach so very near to each other, that it is a difficult task to discriminate them with accuracy. We have little doubt that the _Pancratium foliis amplis ovatis_ of Ehret (Trew's Plantæ Selectæ, tab. 28.) belongs to our plant, notwithstanding the absence of the little teeth between the lobes of the nectary. Indeed, that character appears so variable in the synonyms commonly given to this species, that we are rather inclined to doubt of its constancy. Neither are the painters of those days always safely to be trusted in such minutiæ. Mr. Lambert, who favoured us with the specimen in March 1808, informs us that he received the bulbs from Lord Seaforth, on his return to England from the West Indies, from the _Pancratium caribæum_,

cultivated in the same collection. It is certainly distinct; the blossoms are extremely fragrant, and we are not yet certain whether the amœnum and fragrans of botanists may not be the same species.

[Illustration]

PLATE DLVII.

PERIPLOCA AFRICANA.

African Periploca.

CLASS V. ORDER II.

PENTANDRIA DIGYNIA. Five Chives. Two Pointals.

ESSENTIAL GENERIC CHARACTER.

CONTORTA. Nectarium ambiens genitalia, filamenta 5, exserentia.

CONTORTED. Honey-cup surrounding the stamens. Threads 5, standing out.

SPECIFIC CHARACTER.

PERIPLOCA foliis ovato-acutis, pilosis: floribus corymbosis: caule volubili, hirsuto. _Willd. Sp. Pl._

PERIPLOCA with ovate-pointed hairy leaves: flowers corymbose: stem twining and hairy.

REFERENCE TO THE PLATE.

1. The empalement. 2. The outer part of the blossom. 3. The tubular part of the same detached. 4. The same spread open. 5. One of the lobes of the nectary surrounding the parts of fructification. 6. Seed-buds, chives, and pointals, magnified.

* * * * *

The Periploca Africana is at present a rare plant to the gardens, although, according to Donn's Catalogue, it has been introduced to this country as long ago as the year 1726. There are several figures of it among the older botanists, but not one that does it any justice, as an ornamental green-house plant, which it undoubtedly is, and continues in bloom almost from June till January.

Our figure represents the entire plant, just as we received it from Messrs. Whitley and Brames.

[Illustration]

PLATE DLVIII.

FERULA PERSICA.

Persian Ferula.

CLASS V. ORDER II.

PENTANDRIA DIGYNIA. Five Chives. Two Pointals.

ESSENTIAL GENERIC CHARACTER.

FRUCTUS ovalis, compresso-planus, striis utrinque 3.

FRUIT oval, flatly compressed, with three stripes on both sides.

SPECIFIC CHARACTER.

FERULA foliis supra-decompositis: foliolis multifidis, decurrentibus: umbellâ primordiali sessili.

FERULA with leaves more than doubly compound: leaflets many-cleft and decurrent: the first umbel of flowers sessile.

REFERENCE TO THE PLATE.

1. A perfect flower. 2. A male or abortive flower. 3. The pointals.

* * * * *

Assa fœtida grows naturally near Gilan in Persia; and from seeds sent from thence to the Academy at St. Petersburgh plants were obtained, two of which were sent to Dr. Hope at Edinburgh, by Dr. Guthrie, to whom they had been presented by Professor Pallas, in whose herbarium we have seen specimens of it, but without fructification. One of these plants flowered and ripened seeds in the Botanic Garden at Edinburgh, and is described by Dr. Hope in the lxxvth vol. of the Philosophical Transactions, and a figure annexed, the only one hitherto published of the species; the Assa fœtida of Kæmpfer being undoubtedly a different plant. Our specimens were obligingly communicated by Dr. Williams from the Botanic Garden at Oxford; which, with that of Edinburgh above mentioned, the Cambridge Garden, the Physic Gardens at Chelsea, and Mr. Dickson's private collection at Croydon, are the only gardens in Britain, as we are informed, that yet possess the plant. The gum exudes from the roots, which are tuberous and perennial, on the slightest incision being made; and every part of the plant, even to the extremities of the leaves, smells strongly of it. It is hardy enough to bear our climate, and even ripen its seeds in mild seasons. It is not improbable that at a future time we may be furnished with this valuable article of the Materia Medica, of English growth. The long list of its virtues mentioned by Dr. Woodville we need not here enumerate; its reputation as a cordial for low spirits alone, in these days, entitles it to notice.

[Illustration]

PLATE DLIX.

CAMELLIA JAPONICA, _semi-duplex_.

Semidouble-flowered Camellia.

CLASS XVI. ORDER VI.

MONADELPHIA POLYANDRIA. Threads united. Many Chives.

ESSENTIAL GENERIC CHARACTER.

CALYX imbricatus, polyphyllus: interioribus majoribus.

EMPALEMENT tiled, many-leaved: the inner ones the largest.

SPECIFIC CHARACTER.

CAMELLIA floribus semi-duplicibus, staminibus divergentibus in petalos.

CAMELLIA with semi-double flowers, the stamens growing into petals.

REFERENCE TO THE PLATE.

1. The empalement. 2. The stamens growing into petals. 3. Seed-bud and pointals. 4. A transverse section of the seed-bud.

* * * * *

This Camellia with semi-double flowers was communicated to us by Mr. Davey, nurseryman and florist in the King's Road, Chelsea; who informs us it was a cutting from a plant brought by a gentleman from the coast of China, and regarded as distinct in its flowers from all those in cultivation with us. It certainly has a very different appearance; and as every variety in this short but splendid genus is particularly admired and sought after, this one, which possesses parts of its botanic character entire, will doubtless be considered by the amateurs of plants in general as a variety equally interesting.

[Illustration]

PLATE DLX.

VEREA ACUTIFLORA.

Pointed-flowered Verea.

CLASS VIII. ORDER IV.

OCTANDRIA TETRAGYNIA. Eight Chives. Four Pointals.

ESSENTIAL GENERIC CHARACTER.

CALYX 4-phyllus. Corolla hypocrateriformis, 4-fida: tubo ventricoso, Nectaria 4, ad basin germinum. Capsulæ 4, superæ, 1-loculares, polyspermæ.

EMPALEMENT 4-leaved. Blossom funnel-shaped, 4-sided: tube bellied. Nectaries 4, at the base of the seed-buds. Capsules 4, above, one-celled, many-seeded.

SPECIFIC CHARACTER.

VEREA foliis lato-lanceolatis, oppositis, crenatis, crassis: floribus paniculatis, terminalibus: corollis albentibus: laciniis oris acutissimis.

VEREA with leaves broadly lance-shaped, opposite, scolloped, and thick. Flowers paniculated and terminal. Blossom whitish: segments of the border very pointed.

REFERENCE TO THE PLATE.

1. The empalement. 2. A blossom spread open. 3. Seed-buds and pointals. 4. The same magnified.

* * * * *

This new species of Verea flowered (we believe, for the first time in this country) in the collection of the Hon. C. Greville at Paddington, whence our drawing was taken. The foliage is compact, and rather handsome. The flowers are by no means specious; but, as it blossoms in the depth of winter, its rivals are but few. This considered, with the addition of its novelty, renders it a valuable acquisition to the hot-stove.

[Illustration]

PLATE DLXI.

XERANTHEMUM FRAGRANS.

Fragrant Xeranthemum.

CLASS XIX. ORDER II.

SYNGENESIA POLYGAMIA SUPERFLUA. Tips united Superfluous.

ESSENTIAL GENERIC CHARACTER.

RECEPTACULUM paleaceum aut nudum. Pappus setaceus. Calyx imbricatus, radiatus: radio colorato.

RECEPTACLE chaffy, or naked. Feather bristly, Empalement tiled, rayed: the ray coloured.

SPECIFIC CHARACTER.

XERANTHEMUM foliis undulatis, lanatis, apice reflexis: floribus parvis, odoratis, terminalibus: radiis calycis exterioribus rubris: radio interiore albo.

Habitat ad Caput Bonæ Spei.

XERANTHEMUM with waved woolly leaves reflexed at the point: flowers small, sweet-scented and terminal: the outer rays of the empalement red, the inner one white.

Native of the Cape of Good Hope.

REFERENCE TO THE PLATE.

1. A scale from the outer ray of the empalement. 2. A scale from the inner ray. 3. A flower of the disk.

* * * * *

This little Xeranthemum is a native of the Cape, perfectly new, and very sweet-scented. As fragrance is very unusual in this fine tribe of plants, we have on that account considered it as a good specific title. It was introduced to the Clapham gardens about the year 1803; and as we have not seen it since that period, we are inclined to think it is not at present in this country. In the herbarium of A. B. Lambert, esq. we found a fine native specimen of an unnamed species very much resembling our plant, but with a profusion of flowers--a habit which ours would in all probability have assumed as soon as it had been familiarized to the change of climate.

[Illustration]

PLATE DLXII.

CYNANCHUM BICOLOR.

Two-coloured Cynanchum.

CLASS V. ORDER II.

PENTANDRIA DIGYNIA. Five Chives. Two Pointals.

ESSENTIAL GENERIC CHARACTER.

CONTORTA. Nectarium cylindricum, quinque-dentatum.

CONTORTED. Honey-cup cylindrical, five-toothed.

SPECIFIC CHARACTER.

CYNANCHUM foliis cordatis, acutis, pilosis: floribus in umbellis proliferis: corollis bicoloribus: petalis ad basin hirsutis: caule volubili.

CYNANCHUM with heart-shaped, pointed, hairy leaves: flowers grow in proliferous umbels: blossoms two-coloured: petals hirsute at the base: stem twining.

REFERENCE TO THE PLATE.

1. The empalement. 2. A blossom spread open. 3. The parts of fructification magnified. 4. The seed-bud, shaft, summit, and chives. 5. The same magnified.

* * * * *

This Cynanchum is, we believe, a perfectly new species, and continues to flower during the summer and autumnal months, running to a great length. In that, as well as in other particulars, it bears a considerable resemblance to the Cynanchum extensum of Jacquin’s Icones, but is far superior to that species from its petals being enlivened with a rich purple spot, a slight tinge of which is even visible on the smallest buds. There is an abundant succession of bloom, and the flowers appear to expand with freedom. Our drawing was made last August from a fine plant in the hot-stove of the Countess de Vandes.

[Illustration]

PLATE DLXIII.

MIMOSA ELEGANS.

Elegant Mimosa.

CLASS XXIII. ORDER I.

POLYGAMIA MONŒCIA. Various Dispositions upon one Plant.

ESSENTIAL GENERIC CHARACTER.

HERMAPH. Calyx 5-dentatus. Corolla 5-fida. Stamina 5, sive plura. Pistillum 1, legumen.

MASCUL. Calyx 5-dentatus. Corolla 5-fida. Stamina 5-10, sive plura.

HERMAPH. Empalement 5-toothed. Blossom 5-cleft. Chives 5 or more. Pointal 1, a pod.

MALE. Empalement 5-toothed. Blossom 5-cleft. Chives 5-10, or more.

SPECIFIC CHARACTER.

MIMOSA frutescens, inermis: ramis verrucosis foliis bipinnatis, pennis propriis 8-ad 9-jugis, partialibus 20-ad 24-jugis, cum impari ad imum minore; spicis axillaribus oblongis divaricatis.

MIMOSA shrubby, unarmed: with warty branches: leaves doubly winged, the first of 8 or 9 pairs, the second of 20 to 24 with a small odd leaflet at the bottom: spikes of flowers axillary, oblong, and divaricate.

REFERENCE TO THE PLATE.

1. A flower. 2. The same spread open. 3. The same shown from the inner side, one tip magnified. 4. The seed-bud and pointal, summit magnified.

* * * * *

Mimosa elegans is one of the handsomest of the family that yet been introduced from New Holland, and very rare, being at this time in no other private collection in this country, but that of A. B. Lambert, esq. from whom we received our specimens; and in whose conservatory it is now in full flower, his plant being about ten feet high and very much branched, with profusion of flowers. It is hardly possible to express the extreme delicacy of the blossoms. The stamens are united (monadelphous) towards the base, and are above two hundred in a single flower. What an apparatus for the impregnation of a single stigma!

From what we have already seen of the beautiful and interesting plants of this country, cultivators will do well to give them as much both of pot and branch room as their houses will afford; as well for the health of the plant as to advantage the size of its fine foliage, of which the circumscribed scale of our work would only allow us to represent one half.

[Illustration]

PLATE DLXIV.

IXIA CURTA.

Short Ixia.

CLASS III. ORDER I.

TRIANDRIA MONOGYNIA. Three Chives. One Pointal.

ESSENTIAL GENERIC CHARACTER.

COROLLA 6-petala, patens, æqualis. Stigmata tria erectiuscula, patula.

BLOSSOM six petals, spreading and equal. Summits three, nearly upright, and spreading.

SPECIFIC CHARACTER.

IXIA foliis falcatis: floribus alternis, tri-coloribus: caule humili.

Habitat ad Caput Bonæ Spei.

IXIA with scimitar-shaped leaves: flowers alternate, and three-coloured. Stem low.

Native of the Cape of Good Hope.

REFERENCE TO THE PLATE.

1. The two sheaths of the empalement. 2. A blossom spread open. 3. Seed-bud and pointal, summit magnified.

* * * * *

This new species of Ixia was delineated from a plant in the collection of J. Vere, esq. the summer before last, and although low in stature is certainly high in beauty, and surpassed by very few of loftier growth. It flowers about the middle of April, and requires the same treatment as most other Cape species.

[Illustration]

PLATE DLXV.

RUTA LINIFOLIA.

Flax-leaved Ruta.

CLASS X. ORDER I.

DECANDRIA MONOGYNIA. Ten Chives. One Pointal.

ESSENTIAL GENERIC CHARACTER.

CALYX 5-partitus. Petala concava. Receptaculum punctis melliferis decem cinctum. Capsula lobata.

EMPALEMENT 5-parted. Petals concave. Receptacle beset with ten honey-bearing points. Capsule lobed.

SPECIFIC CHARACTER.

RUTA foliis simplicibus, lanceolatis, glabris: filamentis ciliatis: caule simplici, herbaceo.

Habitat in Hispania.

Ruta linifolia. _Willd. Sp. Pl._

RUE with simple leaves, lance-shaped and smooth: threads ciliated. Stem simple and herbaceous.

Native of Spain.

REFERENCE TO THE PLATE.

1. A petal. 2. Empalement, chives, and pointal. 3. A chive. 4. The empalement, seed-bud, and pointal.

* * * * *

The Ruta linifolia is a new plant to the gardens, and we believe is not at present in any other collection but that of Cambridge, where it was raised from seed by Mr. Donn. It is a handsome little herbaceous shrub, and requires the protection of the green-house to preserve it in this climate. Flowers in September and October.

[Illustration]

PLATE DLXVI.

CALLICOMA SERRATIFOLIA.

Sawed-leaved Callicoma.

CLASS XI. ORDER II.

DODECANDRIA DIGYNIA. Stamens 11 to 19. Styles 2.

GENERIC CHARACTER.

FLORES in capitulis subrotundis, pedunculatis; involucro sub 4-phyllo. Calyx 4-5-phyllus, foliolis lanceolatis. Corolla O. Stamina 11-19, calyce triplo longiora, e receptaculo. Styli 2, filiformes: stigmate simplici: germen superum, monoloculare, polyspermum.

FLOWERS in little round heads, upon footstalks; with an involucre of about 4 leaves. Calyx of 4 or 5 leaves, the leaflets lanced. Blossom none. Stamens from 11 to 19, thrice as long as the calyx, growing from the receptacle. Styles 2, thread-shaped. Stigma simple. Germen above, 1-celled, and many-seeded.

REFERENCE TO THE PLATE.

1. A flower. 2. The same spread open, one tip magnified. 3. The seed-bud and pointals. 4. The same magnified.

* * * * *

Callicoma serratifolia is a native of New South Wales, and has now for several years in some choice collections adorned the green-house and conservatory in early spring with its fine heads of flowers; but to whom we are indebted for its first introduction we are uncertain. Some botanists have considered it as a congener of Forster's _Codia_, to which it has certainly a considerable affinity; but as we cannot exactly see the propriety of coupling an apetalous flower having so many stamens with one that is penta-petalous and octandrous, and of which we have no description of the germen or fruit; and there being great probability that more plants of this family may be discovered in the vast tracts of New Holland yet unexplored, we have rather chose to describe it as distinct, than to excuse ourselves by leaving it to be separated at some future period and create more changes of names, a circumstance always to be deprecated and avoided as much as possible by Naturalists. Callicoma is a middle-sized shrub with the leaves finely cottony and whitish on the under side, and has considerable beauty even when out of blossom. It is propagated by layers.

[Illustration]

PLATE DLXVII.

CERATONIA SILIQUA.

Pod-bearing Ceratonia.

CLASS XXIII. ORDER II.

POLYGAMIA DIŒCIA. Many Nuptials on separate Plants.

GENERIC CHARACTER.

HERMAPH. Calyx 5-partitus. Corolla 0. Stamina 5-8. Stylus filiformis. Stigma capitatum. Legumen coriaceum, pulpâ plenum, polyspermum.

HERMAPH. Empalement 5-parted. Blossom none. Chives 5 to 8. Shaft thread-shaped. Summit headed. Pod leathery, full of pulp, and many-seeded.

REFERENCE TO THE PLATE.

1. A flower shown from the outside. 2. A dry pod a little opened, one seed detached.

* * * * *

Instead of a new plant, we here submit to our readers one that according to the Kew Catalogue has been an inhabitant of our gardens 239 years: but neither Mr. Alton nor Mr. Miller had ever seen it blossom, nor during all this long period have we any account of its flowering in this country. Its male flowers however appeared in the Cambridge Botanic Garden the beginning of last February, and from a specimen communicated by Mr. Donn to A. B. Lambert, esq. the present drawing was taken. Mr. Donn's plant was between 4 and 5 feet high, moderately branched, and had the same treatment as his other green-house shrubs. We are uncertain whether the hermaphrodite or female plant be yet in this country; but as the propagation is principally from seed, we think it is very probable. The stamens in our specimen vary in number, being commonly 5, sometimes 6, and more rarely 8. The fruit is added from a dried legume in the Lambertian collection, which was sent from Spain by the late Abbé Cavanilles, who in his _Icones Plantarum_, _vol._ 2. _p._ 8. and _tab._ 113. (in addition to what was formerly known of the Ceratonia) informs us, that it grows spontaneously on little hills and dry fields in Valencia, and is yet more impatient of cold and moisture than the olive, vast numbers being sometimes killed there by the frost in severe winters. It is in this province also, that the principal cultivation of this useful plant in Spain is situated. The propagation is from seeds, and the diœcious plants are always selected in preference to the hermaphrodites, being better bearers. Some of the more skilful cultivators engraft a male bough upon their female plants for their impregnation, and by this means have no sterile plants in their collections. They flower twice a year, first in February, and again more plentifully in August and September; which is also the time of the fruit's ripening, and the trees are seen at the same time adorned with blossoms, and laden with ripe fruit. Eighty pounds of legumes are sometimes collected from a single tree. They are known to be mature by their putting on a chesnut colour, and are then beaten from the trees by canes of the _Arundo Donax_ from 16 to 20 feet long, with part of their crooked roots left, which serve as hooks. Rain is said to be beneficial to the ripe fruits, and even to improve them after they are laid in heaps on the ground. They are finally dried and stored up in barns for use. The cultivators enumerate three varieties, which they call _Melars_, _Llandars_, and _Costelluts_. The last they distinguish by having larger leaves and of a deeper green, with legumes often a foot long, but with little solidity or sweetness; the second has shorter legumes, but more solid and very sweet; the leaves also are shorter. The first are called Melars (_quasi Melleas_) from _Mel_ honey, of which the fruit contains small drops, and sometimes in such abundance that it distils upon the ground, and is fed upon by the bees. The fruits are the principal food of the cattle in the province of Valencia, and also form part of the sustenance of the poor people. The leaves are used in the preparation of leather. Monsieur Olivier also informs us in his _Travels in the Ottoman Empire_, that the Carob-tree grows all over the Island of Crete, and delights most in stony grounds and the clefts of rocks; that the fruits are conveyed thence to Constantinople, to Syria and Egypt, and serve for food to the poor and to children. They are also an ingredient in the sherbets of which the Mussulmans make daily use.

[Illustration]

PLATE DLXVIII.

LIPARIA SPHÆRICA.

Round-headed Liparia.

CLASS XVII. ORDER IV.

DIADELPHIA DECANDRIA. Two Brotherhoods. Ten Chives.

ESSENTIAL GENERIC CHARACTER.

CALYX quinquefidus, lacinia infima elongata. Corollæ alæ inferius bilobæ. Filamenta alternatim breviora. Legumen polyspermum.

CALYX 5-cleft, the lower segment very long. Wings of the blossom two-lobed on the lower side. Chives alternately shorter. Pod many-seeded.

SPECIFIC CHARACTER.

LIPARIA floribus capitatis; foliis lanceolatis, nervosis, glabris. _Willd. Sp. Pl. vol._ iii.

LIPARIA with flowers in heads; the leaves lance-shaped, nerved, and smooth.

REFERENCE TO THE PLATE.

1. A bract. 2. The empalement. 3. A flower spread open. 4. The chives. 5. The same spread open. 6. Seed-bud and pointal. 7. A back view of the head of flowers.

* * * * *

Africa has long been celebrated as the land of wonders and novelties, and its vegetable as well as animal productions well entitle it to that character. The beauty and astonishing variety of ever-varying Geraniums, delicate Ixias, elegant Ericas, superb Amaryllises, and magnificent Proteas, received from the Cape of Good Hope alone within these few years, and many of them totally unknown before, have given to our gardens that splendour and perpetual novelty which justly make them the admiration of the world. What still more enhances the pleasure is, that the mine is yet unexhausted, as our present charming subject, not before enumerated in any of our catalogues of cultivated plants will testify. Mr. Milne, gardener at Fonthill, well known for his zeal and skill in the cultivation of rare plants, obligingly communicated the specimens. Having forwarded the first a little too early, being struck with the singular beauty, and not knowing the habits of the plant, a fortnight after he forwarded a third specimen fully expanded, from which the figure is taken. Mr. Milne informs us, that he raised the Liparia from Cape seeds some years ago, and has kept it in the conservatory, where it is now in blossom. The plant is branchy, and between four and five feet in height. He thinks he possesses two more new species of the genus raised at the same time, which have not yet blossomed with him.

[Illustration]

PLATE DLXIX.

CEANOTHUS LANIGER.

Woolly Ceanothus.

CLASS V. ORDER I.

PENTANDRIA MONOGYNIA. Five Chives. One Pointal.

ESSENTIAL GENERIC CHARACTER.

PETALA 5, saccata. Bacca sicca, 3-locularis, 3-sperma.

PETALS 5, bagged. Berry dry, three-celled, three-seeded.

SPECIFIC CHARACTER.

CEANOTHUS foliis oblongo-lanceolatis, integerrimis, subtus lanuginosis; ramulis, pedunculis, petiolis, calycibusque hirsutis.

CEANOTHUS with the leaves oblong-lanced, entire, and woolly beneath; the branches, footstalks, flowerstalks, and calyxes hairy.

REFERENCE TO THE PLATE.

1. A flower. 2. A segment of the calyx, with a petal and stamen attached. 3. Seed-bud and pointal.

* * * * *

To New Holland we export criminals for our convenience and safety, and from thence import furs for our covering and flowers for our amusement. So far the balance of trade is in our favour. But by whose hands, or at what time, our present subject was first brought over, we have not been able to learn. The specimen was communicated by A. B. Lambert, esq. in the beginning of April from his collection at Boyton, and we have also seen the plant very finely in flower at Mr. Whitley’s nursery, Brompton. Its woolly leaves and branches, contrasted with the Mimosas and other hard-leaved plants from the same country, make an agreeable variety, and the early blossoms are very ornamental. The plants we have seen are moderate-sized branchy shrubs, are kept in the green-house like other New Holland plants, and require no particular treatment. We have seen more species from the same country in herbariums, and some are now alive in this country, although they have not yet blossomed.

[Illustration]

PLATE DLXX.

JUSTICIA NITIDA.

Shining-leaved Justicia.

CLASS II. ORDER I.

DIANDRIA MONOGYNIA. Two Chives. One Pointal.

ESSENTIAL GENERIC CHARACTER.

CALYX simplex seu duplex. Corolla 1-petala, irregularis. Capsula ungue elastico dissiliens: dissepimentum contrarium; adnatum.

EMPALEMENT simple or double. Blossom one-petalled, irregular. Capsule splitting with an elastic claw: partition contrary to the valve; affixed.

SPECIFIC CHARACTER

JUSTICIA fruticosa: foliis ellipticis, acuminatis: racemis spicæformibus, verticillatis: bracteis minutis: pedicellis calycibusque glabris.

Swartz. _Flora Indiæ occidentalis._

Habitat in insulis Jamaicæ, S. Christophori, Martiniquæ, S. Crucis, et Guadalupæ.

JUSTICIA with a shrubby stem: leaves elliptic and pointed: raceme in the form of a spike, whorled: floral leaves small: footstalks and calyx smooth.

Native of Jamaica, St. Christopher, Martinique, St. Croix, and Guadaloupe.

REFERENCE TO THE PLATE.

1. A flower spread open. 2. Seed-bud and pointal, 3. The capsule. 4. The same split open.

* * * * *

Of this species of Justicia the only figure extant that we know of is a very indifferent representation of it in Sloane’s Jamaica, evidently from a dried specimen. The fine glossy character of the foliage has furnished it with a specific title. The flowers are abundant in succession, but, like most of this genus, of a deciduous or short-lived character. It was introduced to the British gardens, according to Donn’s Catalogue, in 1793, Our drawing was made from a plant brought from the West Indies by Lord Seaforth, which flowered in August 1808 in the hot-stove of A. B. Lambert, esq.

[Illustration]

PLATE DLXXI.

SIDA PATENS.

Spreading Sida.

CLASS XVI. ORDER VIII.

MONADELPHIA POLYANDRIA. Threads united. Many Chives.

ESSENTIAL GENERIC CHARACTER.

CALYX simplex. Stylus multipartitus. Capsulæ plures, mono-seu tri-spermæ.

CALYX simple. Pointal many-parted. Seed-vessels many, one-or three-seeded.

SPECIFIC CHARACTER.

SIDA foliis cordatis, dentatis, longè acuminatis, leviter pubescentibus; pedunculis solitariis petiolis longioribus; corollis patentibus; stylis quinquepartitis; capsulis quinque, birostratis.

SIDA with heart-shaped, toothed, long-pointed, and slightly woolly leaves; solitary flower-stalks longer than the footstalks; spreading corollas, five-parted styles, and five two-beaked capsules.

REFERENCE TO THE PLATE.

1. The empalement. 2. The chives spread open, one tip magnified. 3. Seed-bud and pointal.

* * * * *

Another African novelty introduced by Viscount Valentia in 1806 from Abyssinia; and from specimens obligingly communicated by him from his gardens at Arly the drawing is taken. From the seeds already introduced by his Lordship from that yet unexplored, and hitherto almost inaccessible country, and from the connexions he is now endeavouring to establish there, Mr. Salt, who travelled in his Lordship's suite, being now dispatched on an embassy to the King of that country at Gondar, we may soon hope to have a few more specimens of its vegetable productions; at present as imperfectly known as the sources of the Nile, which have eluded the researches of philosophers above two thousand years.

Sida patens, in the natural arrangement of the genus, should be placed next to _Sida reflexa_ of Cavanilles and Willdenow.

[Illustration]

PLATE DLXXII.

PROTEA SALIGNA.

Willow-leaved Protea.

CLASS IV. ORDER I.

TETRANDRIA MONOGYNIA. Four Chives. One Pointal.

ESSENTIAL GENERIC CHARACTER.

COROLLA 4-fida, seu 4-petala. Antheræ lineares, petalis infra apices insertæ. Calyx proprius, nullus. Semina solitaria.

BLOSSOM four-cleft, or of four petals. Tips linear, inserted into the petals below the points. Cup proper, none. Seeds solitary.

SPECIFIC CHARACTER.

PROTEA foliis obliquis, lanceolatis, pubescentibus: capitulis oblongis, involucratis, terminalibus.

Feminei flores ramos terminant cum cono ovato magnitudine pisi, involucro bicolori circumdato.

Habitat ad Caput Bonæ Spei.

PROTEA with oblique, lance-shaped, hairy leaves: heads of flowers oblong, involucrated, and terminal.

Female flowers terminate the branches with an ovate cone about the size of a pea, surrounded by a two-coloured involucrum.

Native of the Cape of Good Hope.

REFERENCE TO THE PLATE.

1. A flower, one tip magnified. 2. Seed-bud and pointal, summit magnified. 3. Section of a head of flowers from the female plant. 4. Seed-bud and pointal, magnified.

* * * * *

Protea saligna, in the Species Plantarum of Linnæus, is considered as only a variety of P. conifera, but is certainly specifically distinct in its foliage, however resembling in other particulars. Finding, soon after we had made our drawing, a female plant in fine

bloom, we have annexed a branch of it on the same plate, to elucidate as much as possible the apparent confusion that at present seems to pervade this section of the Genus Protea. The P. saligna of Thunberg, enumerated by Willdenow, we have no doubt, describes the female specimen we have represented, the cone being there mentioned as about the size of a pea, and which exactly accords with our figure. The drawings were made from plants introduced to this country from the Cape of Good Hope, in the year 1806, by G. Hibbert, esq.

[Illustration]

PLATE DLXXIII.

MAGNOLIA AURICULATA.

Ear-leaved Magnolia.

CLASS XIII. ORDER VII.

POLYANDRIA POLYGYNIA. Many Chives. Many Pointals.

ESSENTIAL GENERIC CHARACTER.

CALYX 3-phyllus. Petala 6-12. Capsulæ 2-valves, imbricatæ. Semina baccata, pendula.

CUP 3-leaved. Petals 6-12. Capsules 2-valved, tiled. Seeds berried, pendulous.

SPECIFIC CHARACTER.

MAGNOLIA foliis obovato-lanceolatis, basi attenuatis, auritis, glabris, subtus glaucis.

Habitat in America boreali.

MAGNOLIA with obovate lance-shaped leaves, attenuated towards the base, eared, smooth, and glaucous beneath.

Native of North America.

REFERENCE TO THE PLATE.

1. A chive. 2. Seed-bud and pointals.

* * * * *

Amongst the finest hardy exotics that ornament the gardens, the Magnolias are eminently conspicuous. A fine species of that description our figure represents, drawn from a plant seven feet high in the nursery-ground of Messrs. Whitley and Brames, who inform me that it was sent to them from Maryland in North America, by Mr. Bartram, about the year 1793. It does not seed with us, as very few of the genus do; and when any of them appear to have ripened their seed perfectly, we understand they have very rarely if ever vegetated. This species is perfectly hardy, but is with difficulty raised by layers; which accounts for its being (after a period of sixteen years since its first introduction to this country) not so generally known as it deserves to be. It flowers in the month of May.

[Illustration]

PLATE DLXXIV.

PULTENÆA OBCORDATA.

Inversely Heart-leaved Pultenæa.

CLASS X. ORDER I.

DECANDRIA MONOGYNIA. Ten Chives. One Pointal.

ESSENTIAL GENERIC CHARACTER.

CALYX quinque-dentatus, utrinque appendiculatus. Corolla papilionacea, alis vexillo brevioribus. Legumen uniloculare, dispermum.

CUP five-toothed, with an appendage on each side. Blossom butterfly-shaped, with the wings shorter than the standard. Pod of one cell, with two seeds.

See Pultenæa Daphnoides, Pl. XCVIII. Vol. II.

SPECIFIC CHARACTER.

PULTENÆA foliis obcordatis, mucronatis, nitidis.

PULTENÆA with inversely heart-shaped leaves, mucronated, and shining.

REFERENCE TO THE PLATE.

1. The empalement. 2. The vexillum. 3. One of the wings. 4. The two petals of the keel. 5. The chives and pointal, one tip magnified. 6. Seed-bud and pointal.

* * * * *

This nondescript species of Pultenæa is a native of New Holland, and was discovered on Van Diemen's Land by Mr. Littlejohn, one of the residents on Governor Collins's settlement. It possesses lively yellow flowers, and singularly obcordate leaves, and is a handsome addition to the genus Pultenæa, of which it is a genuine member, having the two little appendages on the cup, the principal (although trivial) leading feature that characterizes the genus. Our drawing was made from a specimen communicated by A. B. Lambert, esq. with whom it has flowered for the first time in this country.

PLATE DLXXV.

MARTYNIA DIANDRA.

Diandrous Martynia.

CLASS XIV. ORDER II.

DIDYNAMIA ANGIOSPERMIA. Two Chives longer. Seeds covered.

ESSENTIAL GENERIC CHARACTER.

CALYX 5-fidus. Corolla ringens. Capsula lignosa, corticata, rostro hamata, 4-locularis, 4-valvis.

CALYX five-cleft. Corolla gaping. Capsule woody, covered, with a hooked beak; 4 divisions, and 4 openings.

SPECIFIC CHARACTER.

MARTYNIA caule ramoso, foliis oppositis, cordatis, dentatis, floribus diandris. _Willd. Sp. Pl._

MARTYNIA with the stem branching, leaves opposite, heart-shaped, and toothed, and flowers diandrous.

REFERENCE TO THE PLATE.

1. The empalement. 2. The chives. 3. Seed-bud and pointal. 4. The capsule.

* * * * *

We are glad to have an opportunity of giving a figure of a plant so very ornamental, and so rarely met with in our collections. Martynia diandra is a native of Mexico about Vera Cruz, and requires to be kept in the hothouse, or glass frame with artificial heat, and has much the same delicate texture as the Martynia proboscidea. Of the figures that have before been published of it, that of

Jacquin in his Hortus Schœnbrunnensis, vol. iii. plate 289, is by far the best. A specimen was communicated by A. B. Lambert, esq., in November 1808, and another in May last from a plant which had outlived the winter, and from which the present figure is taken. All the species of Martynia are considered as annuals.

[Illustration]

PLATE DLXXVI.

LITHOSPERMUM TINCTORIUM.

Dyers' Bugloss.

CLASS V. ORDER I.

PENTANDRIA MONOGYNIA. Five Chives. One Pointal.

ESSENTIAL GENERIC CHARACTER.

COROLLA infundibuliformis, fauce perforata, nuda. Calyx 5-partitus.

BLOSSOM funnel-shaped, with the mouth open and naked. Cup 5-cleft.

SPECIFIC CHARACTER.

LITHOSPERMUM villosum caulibus procumbentibus. _Sp. Pl. editio prima._

LITHOSPERMUM hairy. Stem procumbent.

REFERENCE TO THE PLATE.

1. The empalement. 2. A blossom spread open. 3. Seed-bud and pointal.

* * * * *

This rare plant, enumerated in the Hortus Kewensis upon the authority of Sutherland's Catalogue of the Plants in the Physic Garden at Edinburgh, published in 1683, has been long a desideratum in our collections. It grows naturally in dry sandy places about Montpelier, and also in the southern provinces of the Russian empire, from whence we have seen fine specimens collected by Professor Pallas in Mr. Lambert's Herbarium, which now contains the whole collection made at the expense of the Russian Government, during the space of 30 years, by that great naturalist and his assistants. The plant is well calculated for ornamenting rock-works, or light sandy and gravelly borders. The roots are an article of trade, and used to give a red colour to oils, wax, and spirits of wine. Linnæus, after having very properly arranged this plant as a Lithospermum in the first edition of his Species Plantarum, afterwards removed it to the genus Anchusa, which alteration has since been adopted by every editor of his works. The character, however, is decidedly that of a Lithospermum; and the alteration would be difficult to account for, were it not for a memorandum of the late M. L'Heritier (published in the Flore Française), stating that he had seen another plant under that name in the Linnæan herbarium. It therefore appears that Linnæus, after having described the true plant, from his not possessing a specimen of it had afterwards mistaken some species of Anchusa for it. The plant, however, was retained in its proper genus by Gerard in his Flora Gallico-Provincialis, and he has since been followed by Decandolle in the Flore Française. We are aware of Professor Vahl and Willdenow's having given to another Lithospermum the name of tinctorium; but if the genus Arnebia of Forskahl is given up, the characteristic specific of tetrastigma applied to it by Lamarck may be restored. We have never seen any figure of the plant but that of Plenck, Aubriet's in Alyon's Cours de Botanique, and the wooden cut of John Bauhin; the plant figured under the name of Anchusa tinctoria in Woodville's Medical Botany being the Anchusa officinalis. Specimens were communicated by A. B. Lambert, esq., and there is also a fine spreading plant of it now in blossom (May 27th) in the natural ground, in Mr. Harrison's nursery at Brompton.

[Illustration]

PLATE DLXXVII.

PROTEA VIRGATA.

Twiggy Protea.

CLASS IV. ORDER I.

TETRANDRIA MONOGYNIA. Four Chives. One Pointal.

ESSENTIAL GENERIC CHARACTER.

COROLLA 4-fida, seu 4-petala. Antheræ lineares, petalis infra apices insertæ. Calyx proprius, nullus. Semina solitaria.

BLOSSOM four-cleft, or of four petals. Tips linear, inserted into the petals below the points. Cup proper, none. Seeds solitary.

SPECIFIC CHARACTER.

PROTEA foliis linearibus acutis, supra concavis, subtus convexis: floribus confertis, procumbentibus.

Habitat ad Caput Bonæ Spei.

PROTEA with linear pointed leaves, concave above, and convex beneath. Flowers crowded, and lying on the ground.

Native of the Cape of Good Hope.

REFERENCE TO THE PLATE.

1. A flower complete, summit magnified.

* * * * *

The application of specific titles to this wide-spreading family of plants is now become an arduous task; and considering how many of the best are already occupied, an exclusive reference cannot be expected. This species of Protea is altogether new, but bears a powerful resemblance in the flowers to the P. humiflora: but the distinct character of its foliage gives to the tout ensemble a perfect air of novelty; nor is there any figure or description of it extant, that we know of.

Our drawing was made from a fine plant at the nursery of Mr. Knight in the King’s Road, Chelsea.

[Illustration]

PLATE DLXXVIII.

ÆGIPHILA DIFFUSA. Fig. 1.

Spreading Ægiphila.

CLASS IV. ORDER I.

TETRANDRIA MONOGYNIA. Four Chives. One Pointal.

ESSENTIAL GENERIC CHARACTER.

CALYX 4-dentatus. Corolla 4-fida. Stylus semibifidus. Bacca bilocularis, loculis dispermis.

CUP four-toothed. Blossom four-cleft. Shaft cleft half-way down. Berry two-celled, cells two-seeded.

SPECIFIC CHARACTER.

ÆGIPHILA foliis ovato-lanceolatis, longè acuminatis, utrinque glabris; paniculis diffusis axillaribus et terminalibus; staminibus tubo vix excedentibus, stylo longissimo.

ÆGIPHILA with oval-lanced, long pointed leaves, smooth on both sides; panicles spreading, axillary, and terminal; stamens scarcely longer than the tube, and shaft very long.

ÆGIPHILA OBOVATA. Fig. 2.

Inversely Oval-leaved Ægiphila

SPECIFIC CHARACTER.

ÆGIPHILA foliis obovatis acuminatis, utrinque glabris; paniculis axillaribus et terminalibus; pedicellis calycibusque minutè pubescentibus.

ÆGIPHILA with leaves inversely oval, pointed and smooth; panicles axillary and terminal; flower-stalks and calyxes minutely pubescent.

REFERENCE TO THE PLATE.

1. The empalement. 2. A blossom spread open. 3. Seed-bud and pointal, as it appears in the opening buds. 4. The same when fully expanded.

* * * * *

This very natural genus was established by Jacquin from the Bois Cabril of the Creoles in Martinico, a shrub, the young shoots of which are greedily sought for and eaten by their cattle, particularly goats, whence the name (in English) Goatwood; and which Jacquin, following the botanical canon, elegantly turned into Ægiphila. With this species the celebrated Swartz has conjoined the Knoxia of Browne's Jamaica and Manabea lævis of Aublet's Guiana, and added two more species, Æ. fœtida and Æ. trifida, discovered by himself; and Willdenow has yet further augmented it with the Manabea villosa and arborescens of Aublet, and the Nuxia of Lamarck: the last, however, we consider as a very doubtful species. That fine collection of plants from the West Indies, introduced in 1807 by lord Seaforth, and by him presented to A. B. Lambert, esq. and which we have already so often quoted, has brought to our knowledge two more species, which we have denominated diffusa and obovata, from what appeared to us to be their most prominent features. Both shrubs are natives of the West Indies, and were sent to us in flower in August 1808. They are propagated by cuttings, and have not yet ripened seeds in England, but produce flowers annually in abundance during the months of July and August.

[Illustration]

PLATE DLXXIX.

CRATÆGUS AZAROLUS.

The Azarole.

CLASS II. ORDER XII.

ICOSANDRIA DIGYNIA. Twenty Chives. Two Pointals.

ESSENTIAL GENERIC CHARACTER.

CALYX quinquefidus. Petala quinque. Bacca infera, 1-5-sperma.

CUP five-cleft. Blossom five petals. Berry below, with from 1 to 5 seeds.

SPECIFIC CHARACTER.

CRATÆGUS foliis obtusis, subtrifidis, dentatis, pubescentibus.

CRATÆGUS with blunt, pubescent, toothed leaves generally 3-cleft.

REFERENCE TO THE PLATE.

1. A flower spread open. 2. The same shown from the outer side.

* * * * *

The Azarole grows naturally in Italy, in the South of France, in Carniola, and on the banks of the Tanais in the Russian empire where it was found by Gerber in 1741. It grows to be a tree of rather small size, and is much cultivated in Italy, in the South of France, and in Sicily, for the sake of the fruit, which is as large as a cherry, of a fine red colour with sometimes a tinge of yellow, and is said to have a very agreeable flavour. At present the Azarole is very scarce in this country, and we have never seen it in blossom but at Burchall's nursery at Fulham, in May 1808, when our drawing was made. This year the plant has produced no blossoms. To those who are desirous of cultivating the Azarole, and adding another variety to their deserts, we would recommend planting it in well sheltered situations; or perhaps training against a wall, as practised for peaches and other delicate fruits, would be still better. Considerable trees of the Azarole formerly existed in His Majesty's Gardens at Kew, and in those of the Duke or Northumberland at Sion House; and we have lately seen the remains of one in Mr. Swainson's collection at Twickenham; but we are not aware that any exist at present in England. That of Plenck excepted, in His Medical Plants, Pl. 390, we believe no other coloured figure of it has before been published.

[Illustration]

PLATE DLXXX.

MESEMBRYANTHEMUM ACINACIFORME.

Scimitar-leaved Mesembryanthemum.

CLASS XII. ORDER IV.

ICOSANDRIA PENTAGYNIA. Twenty Chives. Five Pointals.

ESSENTIAL GENERIC CHARACTER.

PETALA valde numerosa, linearia, basi cohærentia.

PETALS very numerous, linear, cohering at the base.

SPECIFIC CHARACTER.

MESEMBRYANTHEMUM foliis acinaciformibus: floribus amplissimis, lætè purpureis.

Dillenii Hortus Elthamensis, tab. CCXI.

FIG-MARYGOLD with scimitar-shaped leaves: flowers very large, and of a bright purple colour.

REFERENCE TO THE PLATE.

1. The empalement, seed-bud, and pointals.

* * * * *

Throughout this extensive tribe of plants, this is the most splendid species of Mesembryanthemum we are at present acquainted with; and although an old plant in the gardens, it is quite a rarity to meet with it in flower. Our specimen is from the collection of Mr. Trimmer, of Kew Bridge, whose method of forcing it into bloom may be worth the attention of cultivators. It is by training it up against the glass, and watering it very sparingly; indeed, so little water is requisite for many of the succulent plants, that we have seen them thrive very well without any, except what they absorb from the humidity of the atmosphere in the descending dews.

[Illustration]

PLATE DLXXXI.

SALIX VIOLACEA.

Violet-coloured Willow.

CLASS XXII. ORDER II.

DIŒCIA DIANDRIA. Chives and Pointals on different Plants. Two Chives.

ESSENTIAL GENERIC CHARACTER.

* _Masculi flores._

AMENTUM cylindraceum. Calyx squamosus. Corolla 0. Glandulæ baseos nectariferæ.

* _Feminei flores._

AMENTUM cylindraceum. Calyx squamosus. Corolla 0. Stylus 2-fidus. Capsula 1-locularis, 2-valvis. Semina papposa.

* _Male flowers._

CATKIN cylindrical. Empalement squamous. Blossom none. Glands at the base, bearing honey.

* _Female Flowers._

CATKIN cylindrical. Empalement squamous. Blossom none. Shaft 2-cleft. Capsule 1-locular, 2-valved. Seeds downy.

SPECIFIC CHARACTER.

SALIX foliis lanceolatis, acuminatis, serrulatis, glabris, subtus glaucis: ramis pulvere violaceo tectis.

WILLOW with lance-shaped leaves finely sawed, smooth, and glaucous beneath: branches covered over with a violet-coloured powder.

REFERENCE TO THE PLATE.

1. A male flower. 2. A bit of the lower part of the stem with some of the powder rubbed off.

* * * * *

This fine species of willow is remarkable, first, for the gigantic size of its shoots, rising to the height of ten and sometimes twelve feet in one season; secondly, for their superior tenacity, being yet more tough than the common Osier; and thirdly, for the singular blue powder (considerably resembling that found upon the Orleans plum) with which they are always covered; and which, when any part of it has been accidentally rubbed off, is very quickly regenerated. It is said to be a native of Russia or Siberia, and to have been introduced by Mr. John Bell of Sion Gate about the year 1798. Whether it may or may not be the same species as Salix acutifolia of Willdenow, which he published without having seen the fructification, we leave to those who have seen his specimen to determine.

Our specimens are from the collection of A. B. Lambert, esq. who informs us that it produces in April male flowers annually at Boyton, and besides its great utility is a very ornamental plant.

[Illustration]

PLATE DLXXXII.

PROTEA MELLIFERA ALBIFLORA.

White-flowered Honey-bearing Protea.

CLASS IV. ORDER I.

TETRANDRIA MONOGYNIA. Four Chives. One Pointal.

ESSENTIAL GENERIC CHARACTER.

COROLLA 4-fida, seu 4-petala. Antheræ lineares, petalis infra apices insertæ. Calyx proprius, nullus. Semina solitaria.

BLOSSOM four-cleft, or of four petals. Tips linear, inserted into the petals below the points. Cup proper, none. Seeds solitary.

SPECIFIC CHARACTER.

PROTEA foliis lanceolatis ellipticis: capituloque terminali, magno, albo.

Habitat ad Caput Bonæ Spei.

PROTEA with elliptic lance-shaped leaves: head of flowers terminal, large, and white.

Native of the Cape of Good Hope.

REFERENCE TO THE PLATE.

1. Seed-bud, chives, and pointal.

* * * * *

Whether we consider this Protea as a species, or only a variety, it well deserves a representation. The only plant we have ever seen of it, and from whence our figure was taken, was in the collection of the Duke of Northumberland at Sion House, in the year 1807. Its unequivocal claim to the specific title of mellifera we unawares experienced, as, in bending the plant a little forward to view the interior of its flowers, (the plant being near seven feet high,) it literally poured out a stream of nectareous juice, the cup being filled with honey as high as the imbrications could possibly contain it.

[Illustration]

PLATE DLXXXIII.

LONICERA JAPONICA.

Japanese Woodbine.

CLASS V. ORDER I.

PENTANDRIA MONOGYNIA. Five Chives. One Pointal.

ESSENTIAL GENERIC CHARACTER.

COROLLA 1-petala, irregularis. Bacca polysperma, bilocularis, infera.

BLOSSOM of one petal, irregular. Berry many-seeded, 2-celled, below.

SPECIFIC CHARACTER.

LONICERA foliis perennantibus petiolatis villosis: caule volubili.

Lonicera japonica. _Willd. Sp. Pl._

LONICERA with ever-green downy leaves upon footstalks, and a twining stem.

REFERENCE TO THE PLATE.

1. A flower spread open. 2. The seed-bud and pointal.

* * * * *

This far-fetched and yet rare species of “the luscious woodbine” is the Kin-gin-qua, or Gold and Silver Flower, of the Japanese, as we learn from Kæmpfer and Thunberg. The same name is also affixed to a Chinese drawing of the plant, a copy of which we have seen in the collection of A. B. Lambert, esq. From the same drawing we learn that the flowers come sometimes more in heads, and much more numerous than in our specimen; which may probably be accounted for from the plants being kept here in the green-house. Being an ever-green, like the Minorca and American twining honey-suckles, the species is the more desirable. It was introduced, we are informed, from China about the year 1805, and our drawing was taken in July 1809, in the garden of the Count de Vandes at Bayswater.

[Illustration]

PLATE DLXXXIV.

PHLOMIS SAMIA.

Samian Phlomis.

CLASS XIV. ORDER I.

DIDYNAMIA ANGIOSPERMIA. Two Chives longer. Seeds covered.

ESSENTIAL GENERIC CHARACTER.

CALYX angulatus. Corollæ labium superius incumbens, compressum, villosum.

CUP angled: upper lip of the corolla incumbent, compressed and downy.

SPECIFIC CHARACTER.

PHLOMIS caule hirsuto, foliis cordatis, crenatis, subtus tomentosis, bracteis tripartitis subulatis mucronatis calycem æquantibus. _Willd. Sp. Pl. 3. p. 120._

PHLOMIS with a hairy stalk: leaves heart-shaped, scolloped, and cottony underneath: bracts 3-parted, awl-shaped, as long as the cup.

REFERENCE TO THE PLATE.

1. The empalement. 2. A flower spread open. 3. Seed-bud and pointal.

* * * * *

This curious species appears to have been introduced by Mr. Miller; but, not being enumerated in the Hortus Kewensis, nor the Catalogue of the Cambridge Botanic Garden, must have been since lost. Indeed Mr. Miller informs us, that the severe winter of 1740 destroyed all the plants of it then in England. A. B. Lambert, esq. who communicated the specimens in July last from his garden at Boyton, informs us that Dr. Williams, regius professor of botany at Oxford, favoured him with the plant; and his predecessor Dr. Sibthorpe, who made two journeys into Greece to enrich us with the natural history of that interesting country, was probably the re-introducer. The name Samia is derived from the island of Samos; but Monsieur Desfontaines informs us (in his Flora Atlantica) that the original Samian plant of Tournefort and the Phlomis Samia of Linnæus (which he found wild about Mount Atlas) are different species. Both may possibly be natives of Samos: the posthumous Flora Græca of Dr. Sibthorpe, now publishing by his friend Dr. Smith, will, we trust, decide it. There is no prior figure of the plant.

[Illustration]

PLATE DLXXXV.

SOPHORA JAPONICA.

Japanese Sophora.

CLASS X. ORDER I.

DECANDRIA MONOGYNIA. Ten Chives. One Pointal.

ESSENTIAL GENERIC CHARACTER.

CALYX 5-dentatus, supernè gibbus. Corolla papilionacea: alis longitudine vexilli. Lomentum moniliforme.

CUP five-toothed, swelling above. Blossom butterfly-shaped, with wings the length of the keel. Pod necklace-shaped.

SPECIFIC CHARACTER.

SOPHORA foliis pinnatis: foliolis pluribus ovatis glabris: caule arboreo. _Willd. Sp. Pl._

SOPHORA with winged leaves: the leaflets numerous, ovate, and smooth: stem arborescent.

REFERENCE TO THE PLATE.

1. The empalement. 2. The vexillum. 3. One of the alæ. 4. The carina. 5. The chives. 6. The seed-bud and pointal.

* * * * *

Sophora japonica is the largest species of that genus at present known. The specimen exhibited is from a tree more than 40 feet high, in the collection of John Ord, esq. at Purser's Cross, Fulham, which was planted by himself about fifty years ago. Our attachment to even the inanimate companions of our youth, and the pleasure we derive from them, are thus beautifully expressed by one of our English poets (Cowley, we believe):

"A wood coëval with himself he sees; And loves his old cotemporary trees."

Mr. Ord obtained his plants of Mr. Gordon, nurseryman at Mile End, who introduced the species from China in the year 1753. The first time of its flowering in this country, we learn, was in his Grace the Duke of Northumberland's collection at Sion, in August 1797. The only figure we have seen is in Jacquin's Hortus Schœnbrunnensis, vol. iii. Burmann, in his Flora Indica, and after him Linnæus, describe the flowers as white. In Mr. Ord's garden they are of a faint yellow, as in the figure of Jacquin; and in the specimens which we have seen from Sion House, faint yellow tinged with purple. Excellent in the study of flowers is the maxim of Virgil,

".... Nimiùm ne crede colori."

[Illustration]

PLATE DLXXXVI.

LILIUM SPECIOSUM.

Showy Lily.

CLASS VI. ORDER I.

HEXANDRIA MONOGYNIA. Six Chives. One Pointal.

ESSENTIAL GENERIC CHARACTER.

COROLLA 6-petala, campanulata: nectarium linea longitudinalis: capsulæ valvulis pilo cancellato connexis.

BLOSSOM 6-leaved, bell-shaped. Nectary a longitudinal line. Valves of the seed-pod connected with a lattice-work of hairs.

SPECIFIC CHARACTER.

LILIUM foliis sparsis, ovato-oblongis: floribus cernuis mox revolutis: caule ramoso.

Lilium speciosum. _Willd. Sp. Pl._

LILY with scattered oval-oblong leaves: the flowers nodding, soon rolled back, and the stem branching.

REFERENCE TO THE PLATE.

1. Seed-bud and pointal.

* * * * *

We can but seldom have the pleasure of recording so valuable an acquisition to our collections as this truly magnificent species, introduced from China by the Right Hon. Sir Joseph Banks about the year 1807, and a figure of it also published by him in 1791, being plate 47 of the Icones Selectæ, from drawings made in Japan by Kæmpfer, and now deposited in the British Museum. The

woolliness and bulbs on the stem in our specimen, and the want of constriction at the base of the leaves, (if any such ever exists in nature,) differ considerably from the figure above quoted; but the strong general resemblance, and a consideration of the many variations to which other species of this genus are subject, induce us to regard it as a variety from the same common stock. The stem rises to between three and four feet in height, and sometimes even higher; and produces from three to nine or more flowers, according to its strength and situation. The bulb which it produces from the base of every leaf forms a future plant, and thus to unrivalled beauty adds abundance. Its time of flowering enhances its value, being in August, when all other lilies have deserted the parterre. Mr. Williams, nurseryman at Turnham Green, favoured us with the specimen.

[Illustration]

PLATE DLXXXVII.

CORCHORUS? JAPONICUS _flore pleno_.

Japanese Corchorus with double flowers.

CLASS XIII. ORDER I.

POLYANDRIA MONOGYNIA. Many Chives. One Pointal.

ESSENTIAL GENERIC CHARACTER.

COROLLA 5-petala. Calyx 5-phyllus, deciduus. Capsula plurivalvis, loculamentosa.

BLOSSOM of 5 petals. Cup 5-leaved, falling off, Fruit with many valves, subdivided.

SPECIFIC CHARACTER.

CORCHORUS capsulis rotundis glabris, foliis duplicato-serratis.--_Flora Japonica, p. 227._

CORCHORUS with round smooth capsules, and the leaves doubly sawed.

REFERENCE TO THE PLATE.

1. The pointals.

* * * * *

This elegant shrub is amply described in the Flora Japonica of Professor Thunberg, who found it growing naturally about Nagasaki, Miaco, and various parts of the Japanese empire; where it is also commonly cultivated for ornament. The double variety here figured he particularly specifies as naturally adorning the country about Miaco. In Houttuyn’s Pflanrensystem, vol. vii. plate 54, there is also an engraving of it. The single-flowered has not yet been introduced to this country. The time of blossoming is in early spring: but it does not appear to confine itself to that season, as we have been favoured with fresh specimens at various seasons from April to October; and we may therefore safely predict its being long a favourite with cultivators. The flexile twigs starred with blossoms look at a little distance like garlands, and extend when supported to a great length. All the flowers that we have seen are from 5-to 8-gynous; which, with the singular form of the capsule, makes us consider it as a very doubtful species of Corchorus. The Japanese name is Jamma Buki.

Our figure is taken from specimens communicated by Mr. Milne of Fonthill, who informs us that his plant now growing in the conservatory is ten feet high. We first observed it in bloom early last spring at Messrs. Colville’s, and in several other collections during the summer, but smaller both in flowers and leaves.

[Illustration]

PLATE DLXXXVIII.

SIDA HASTATA.

Halberd-leaved Sida.

CLASS XVI. ORDER VIII.

MONADELPHIA POLYANDRIA. One Brotherhood. Many Chives.

ESSENTIAL GENERIC CHARACTER.

CALYX simplex, angulatus. Stylus multi-partitus. Capsulæ plures, 1-seu 3-spermæ.

CUP simple-angled. Shafts many-parted. Seedpods many, one-to three-seeded.

SPECIFIC CHARACTER.

SIDA foliis inferioribus cordatis angulatis, superioribus elongato-hastatis; pedunculis axillaribus, unifloris, longissimis.

Sida hastata, _Willd. Sp. Pl._

SIDA with the lower leaves somewhat heart-shaped and angled, the upper ones long-halberd-shaped; flower-stalks very long, one-flowered, and axillary.

REFERENCE TO THE PLATE.

1. The chives spread open. 2. The pointals.

* * * * *

This species was first properly distinguished and described by the Spanish botanist Cavanilles in his Dissertatio de Sida, where he has also given a figure of it; and upon this with the Sida cristata and Dilleniana his genus Anoda was founded. Other botanists, however, have not agreed to this division, and both Professor Martyn in his Dictionary and Willdenow still consider them as Sidas of which they now enumerate 99 species; and the new species brought from Abyssinia by Lord Valentia, and published in our 117th number, completes the century. Most of the species have been destined by nature to blossom beneath a milder sky than ours; the Sida hastata was found by the French botanist Dombey growing naturally in Peru and Lima in moist places; and A. B. Lambert, esq., who favoured us with the specimen last September, received the seeds from the East Indies, The two other varieties of this enumerated by Cavanilles and Willdenow we have not seen. The plant is annual, and has yet been kept in the stove.

[Illustration]

PLATE DLXXXIX.

GLADIOLUS ANGUSTUS, _minor_.

Small Narrow-leaved Cornflag.

CLASS III. ORDER I.

TRIANDRIA MONOGYNIA. Three Chives. One Pointal.

ESSENTIAL GENERIC CHARACTER.

COROLLA sexpartita, ringens. Stamina adscendentia.

BLOSSOM six divisions, gaping. Chives ascending.

SPECIFIC CHARACTER.

GLADIOLUS foliis linearibus, longis, costatis; corollis flavescentibus; petalis tribus inferioribus rubro notatis.

Gladiolus angustus. _Jacquin. Icones, tab. 252, vol. ii._

CORNFLAG with linear leaves long and ribbed: blossom yellowish; the three lower petals marked with red.

REFERENCE TO THE PLATE.

1. The outer sheath of the empalement. 2. The inner sheath. 3. A blossom spread open. 4. Seed-bud and pointal. 5. Flower of a larger variety.

* * * * *

Our figure represents a plant from the nursery of Mr. Williams, and which we at first were inclined to regard as a distinct species from the Gladiolus angustus of Jacquin: but meeting soon after with a plant in the collection of Messrs. Whitley and Brames, of larger dimensions, (a flower of which we have represented,) its intermediate character appears, upon comparison, to connect a regular chain of variation, the smallest link of which is (at present) the one now figured.

Both plants are of easy culture, requiring no other treatment than what is common to bulbs of this class.

[Illustration]

PLATE DXC.

MESPILUS ODORATISSIMA.

Sweet-scented Mespilus.

CLASS XII. ORDER V.

ICOSANDRIA PENTAGYNIA. Twenty Chives. Five Pointals.

ESSENTIAL GENERIC CHARACTER.

CALYX 5-fidus. Petala 5. Bacca infera, 5-sperma.

CALYX 5-cleft. Petals 5. Berry below, 5-seeded.

SPECIFIC CHARACTER.

MESPILUS foliis utrinque pubescentibus, pinnatifidis; laciniis incisis.

MESPILUS with leaves downy on both sides, and wing-cleft; with the segments slit.

REFERENCE TO THE PLATE.

1. The empalement and pointals. 2. A branch of ripe fruit.

* * * * *

For this undescribed species of Mespilus we are indebted to the Right Hon. the Marquis of Bath, who first observed it to be distinct from the Mespilus tanacetifolia, with which it has commonly been confounded, and pointed out the specific differences to Mr. Lambert in 1807. The accuracy of his Lordship's observations we have often verified this summer in the different collections about London, and find the two species quite distinct in fruit, foliage, and bracteæ. Mespilus odoratissima forms handsome dwarf trees, from 6 to 12 feet high in the specimens we have seen. The blossoms appear in June, and are remarkably fragrant, but considerably smaller than in M. tanacetifolia; but this is abundantly compensated by the livelier colour and greater profusion of the fruit with which the boughs are loaded in autumn. The tree called by Professor Pallas Cratægus orientalis, (see the English translation of his Travels in the Crimea, vol. ii. p. 174 and 181,) and which he found cultivated for its fruit in the south-western parts of the Crimea, where it also grows wild on the mountains, is this species, as we have ascertained from his Herbarium; and the little red Medlar found in Anatolia by Tournefort, (see his Travels, vol. ii. p. 322 of the English translation,) noticed by Dr. Smith in his Exotic Botany, is probably the same thing. We were favoured with the specimens both of this and M. tanacetifolia (our next plate) by the Right Hon. the Marchioness of Bath, from Longleat.

[Illustration]

PLATE DXCI.

MESPILUS TANACETIFOLIA.

Tansy-leaved Medlar.

CLASS XII. ORDER V.

ICOSANDRIA PENTAGYNIA. Twenty Chives. Five Pointals.

ESSENTIAL GENERIC CHARACTER.

CALYX 5-fidus. Petala 5. Bacca infera, 5-sperma.

CALYX 5-cleft. Petals 5. Berry below, 5-seeded.

SPECIFIC CHARACTER.

MESPILUS floribus bracteatis; foliis pinnatifidis; laciniis argutè serratis, pubescentibus.

MESPILUS with bracts to the flowers; the leaves wing-cleft, with the divisions sawed and downy.

REFERENCE TO THE PLATE.

1. The empalement and pointals. 2. A branch with ripe fruit.

* * * * *

Neither is this species enumerated in the works of Linnæus. The great French botanist Tournefort, who discovered it on the mountains of Anatolia in 1701, thus describes it: “These mountains produce a fine sort of Azarolíer or Medlar-tree; there are some as big as oaks. Their trunk is covered with a cleft grayish bark; the branches are bushy, and spreading out on the sides; the leaves are in bunches two inches and a half long, fifteen lines broad, shining, a little hairy on both sides, commonly divided into three parts even to the rib, and these parts indented very neatly on the edges, pretty much like the leaves of tansy; the part at the end of the leaf is again divided into three parts. The fruit grow two or three together at the end of the young shoots, and resemble small apples of an inch diameter with five roundings like the ribs of a melon, a little hairy, pale green inclining to a yellow, with a navel raised of five leaves. We sometimes find one or two of these leaves growing out of the flesh of the fruit, or its stalk. The fruit though agreeable is not so pleasant as our Medlar, but I believe it would be excellent if it were cultivated. The Armenians not only eat as much of this as they can, but likewise fill their bags. The short period the tree has been introduced (not above 20 years, as we are informed) will not allow any in England, as yet, to have reached the size above mentioned; and we much doubt whether it may be thought worthy of cultivation here for the fruit: but the beauty of the tree and agreeable fragrance of the blossoms sufficiently recommend it to a place in the pleasure-garden. This and the last described species with the artificial characters of the genus Mespilus have all the natural habits of Cratægus, and show how ill even our most admired systems are calculated to trace and mark these fine gradations, which, while they yet distinguish, closely connect all nature. Too often the hue and cry of “Heretics! Innovators!” thundered out by the schools against all who will not implicitly follow their dogmas, drive the calm and unprejudiced students of nature out of the field. Yet he that discovers one new truth is surely a benefactor to society; but he that defends and inculcates error is a tyrant in the kingdom of Nature.

[Illustration]

PLATE DXCII.

MIMOSA GRANDIFLORA.

Great-flowered Mimosa.

CLASS XXIII. ORDER I.

POLYGAMIA MONOECIA. Flowers Male, Female, and Hermaphrodite, on the same Plant.

ESSENTIAL GENERIC CHARACTER.

HERMAPHRODITI. Calyx 5-dentatus. Corolla 5-fida vel 5-petala. Stamina 4-200. Pistillum 1. Legumen bivalve.

MASCULI. Calyx 5-dentatus. Corolla 5-fida sen 5-petala. Stamina 4-200.

HERMAPHRODITES. Cup 5-toothed. Blossom 5-cleft or 5-petalled. Chives 4 to 200. Shaft 1. Pod two-valved.

MALE FLOWERS. Cup 5-toothed. Blossom 5-cleft, or of 5 petals. Chives 4 to 200.

SPECIFIC CHARACTER.

MIMOSA inermis, foliis bipinnatis, multijugis, ciliatis; racemo composito terminali.

Acacia grandiflora. _Willd. Sp. Pl. 4. p. 1074._

MIMOSA unarmed, with doubly-winged leaves in many pairs and ciliated, and flowers in a compound terminating bunch.

REFERENCE TO THE PLATE.

1. The empalement. 2. The chives spread open. 3. The pointal.

* * * * *

This species, conspicuous by its tall woody stems, large purple blossoms, and delicate foliage, was brought to the Royal Gardens at Kew from India by Mrs. Norman, about the year 1769. It is a plant of quick growth, and blossoms freely, but has never produced any pods in this country. The only figure of it we have seen is that by Reinagle in Dr. Thornton's Illustration of the System of Linnæus. A plate however was finished for L'Heritier, who first described it; but his death prevented its publication. The stamens (as in many other Mimosas) are united near the base. The blossoms open in succession from the bottom of the bunch upwards, and continue great part of the summer. The leaves are deciduous. The specimen was communicated from Boyton by A. B. Lambert, esq. in August.

[Illustration]

PLATE DXCIII.

CROTALARIA TETRAGONA.

Four-sided Crotalaria.

CLASS XVII. ORDER IV.

DIADELPHIA DECANDRIA. Two Brotherhoods. Ten Stamens.

ESSENTIAL GENERIC CHARACTER.

LEGUMEN pedicellatum, turgidum. Stamina omnia connexa.

POD on a stalk, swollen. Stamens all connected.

SPECIFIC CHARACTER.

CROTALARIA caule tetragono, strigoso; petiolis brevibus, foliis oblongo-lanceolatis, acuminatis; stipulis caulem amplexantibus.

CROTALARIA with the stem 4-sided, with flat pressed hairs: short footstalks: leaves oblong-lanced, and pointed: stipules embracing the stem.

REFERENCE TO THE PLATE.

1. The keel. 2. The chives and pointal. 3. Seed-bud and pointal.

* * * * *

This new and very ornamental species is remarkable for having the under lip of the calyx often undivided, and every part of the plant up to the blossom covered with shining close-pressed hairs: nor are they entirely wanting on the blossom; on the lower part of the keel they are very conspicuous, hanging downwards like a little beard. A groove with a fringe on each side runs also along the upper side of the style towards the summit. Two thread-shaped silky stipules rise at the base of every leaf-stalk, and, being reflected backwards, closely embrace the stem. A solitary stipule also rises at the base of each flower-stalk, and two where it unites with the calyx: but these, from their singular situation, must perhaps be considered as bracteæ.

We were favoured with the specimens in November from Lord Valentia's gardens at Arley, along with the Plectranthus barbata. His Lordship received the seeds last year from Dr. Roxburgh in India, by the name of Crotalaria tetragona. The plant appears to be shrubby. No account of the species has before been published. Its place in the genus is near to the Crotalaria juncea figured in our sixth volume.

[Illustration]

PLATE DXCIV.

PLECTRANTHUS BARBATUS.

Bearded Plectranthus.

CLASS XIV. ORDER I.

DIDYNAMIA GYMNOSPERMIA. Four unequal Stamens. Naked Seeds.

ESSENTIAL GENERIC CHARACTER.

CALYX laciniâ summâ majore. Corolla resupinata, ringens; tubo sursùm gibbo vel calcarato.

CUP with the upper division largest. Blossom lying on its back, gaping; tube with a spur above or swelled out.

SPECIFIC CHARACTER.

PLECTRANTHUS racemis bracteatis, bracteis deciduis; foliis ovatis, crenatis, pubescentibus, rugosis, per petioles decurrentibus: corollæ labio superiore emarginato brevissimo; inferiore subovato, concavo, hirsuto.

PLECTRANTHUS with bracts to the bunches, bracts falling off: the leaves oval, scolloped, downy and wrinkled, running down the footstalks; the upper lip of the blossom short, and slightly notched; the lower nearly ovate, compressed and hairy.

REFERENCE TO THE PLATE.

1. The empalement. 2. A blossom with the segments cut off to expose the chives. 3. The seed-bud and pointal, summit magnified.

* * * * *

The stem of Plectranthus is four-sided with blunt corners, and woolly. The leaves are fleshy, minutely dotted on both sides, and border their footstalks down to the stem. The flower-stalks, the lower part of the cups, and under lip of the blossom, are set with stiff clear bristles. The tube of the blossom is without a spur, and swelled on the upper side. Every part of the plant has a powerful fragrance. The specimens were communicated in November by Mr. Giddings, gardener to Lord Valentia at Arley; with a letter stating, that he raised the plants from Abyssinian seeds sent home by his Lordship about four years ago, and that they grow at Arley to about two feet in height, and thrive with the common treatment of stove plants.

The first species known of this genus, Plectranthus punctatus, the Ocymum punctatum of Linnæus, was also brought from Abyssinia by the celebrated Bruce.

[Illustration]

PLATE DXCV.

PANAX FRUTICOSUM.

Shrubby Panax.

CLASS XXIII. ORDER II.

POLYGAMIA DIŒCIA. Flowers Male, Female, and Hermaphrodite on different Plants.

ESSENTIAL GENERIC CHARACTER.

HERMAPHRODITUS. Umbella. Calyx 5-dentatus, superus. Corolla 5-petala. Stamina 5. Styli 2 vel 3, sæpe cohærentes. Bacca 2-vel 3-sperma, infera.

HERMAPHRODITE. An umbel. Cup 5-toothed, above. Blossom 5-petalled. Stamens 5. Shafts 2 or 3, sometimes cohering. Berry 2-or 3-seeded, below.

The male or female flowers we have never seen.

SPECIFIC CHARACTER.

PANAX foliis supradecompositis, dentato-ciliatis; caule fruticoso. _Willd. Sp. Pl._

PANAX with leaves more than doubly compound, ciliated with little teeth; the stem shrubby.

REFERENCE TO THE PLATE.

1. Empalement, chives, and pointals. 2. The pointals. 3. The plant in miniature.

* * * * *

On examining the flowers of this curious and rare species of Panax, we were a little startled to find how widely they differed from the character of the genus; being trigynous, and the berry three-seeded. Professor Jacquin has also observed the same variation in the flowers of P. aculeatum (see his Icones, tab. 634); and fifty years ago Trew observed and delineated the same number of styles in Panax trifolium, one of the original species upon which the genus was established. Nor had this escaped the scrutinizing eye of that profound observer of nature Bernard Jussieu. From these authorities, therefore, in consonance with our own observations, we have enlarged the character of the genus to include the species. Panax fruticosum, as we learn from Rumphius's Herbarium Amboinense, vol. iv. p. 78 and 79, rises to between five and six feet in height, with a stem as thick as a man's arm, and grows naturally in the Island of Ternate, where it is also much cultivated by the natives for food, medicine, and œconomy; being planted to separate the areas of their gardens and mark the boundaries of their fields. The boiled leaves are eaten as greens, and a decoction both of the leaves and root is used successfully in nephritic diseases, for which they also sometimes prescribe the roots to be eaten raw. The fame of the plant as a powerful diuretic is also great in Amboyna; where, as well as in Ternate, it is commonly planted both for ornament and use. Labillardiere, the French botanist, who accompanied the expedition that sailed in quest of the unfortunate Lapeyrouse, informs us (in his account of the voyage) that when at Amboyna he found this plant encircling the tomb of the venerable Rumphius, its first described.

Nature he loved; with her he spent his hours: The grateful goddess wreathes his tomb with flowers!

The famous _Gin-seng_, to which the Chinese attribute such extraordinary virtues, and which, as Osbeck informs us, was commonly sold in their shops in 1751 (see his Travels, English edit. p. 222) for from 30 to 40 times its weight in silver, and which one of their Emperors, 40 years before that, sent 10,000 Tartars in quest of at once, is said by that author to be a species of Panax; but the plant is yet unknown in Europe. Panax fruticosum, we are informed, was introduced to this country about the year 1800, and requires to be kept in the hot-house. The specimen was communicated from Boyton by A. B. Lambert, esq.

[Illustration]

PLATE DXCVI.

LAURUS CINNAMOMUM.

Cinnamon Tree.

CLASS IX. ORDER I. OR CLASS XXII. ORDER VII.

ENNEANDRIA MONOGYNIA, or _DIŒCIA POLYANDRIA_. Nine Stamens. One Style, or Male and Female Flowers on different Plants. Stamens more than Seven.

ESSENTIAL GENERIC CHARACTER.

CALYX nullus. Corolla 6-partita, glandulis tribus germen cingentibus. Filamenta interiora glandulifera. Drupa 1-sperma.

CUP none. Blossom 6-parted. Glands three, surrounding the germen. Inner filaments bearing glands. Berry dry, one-seeded.

SPECIFIC CHARACTER.

LAURUS foliis trinerviis ovato-oblongis, nervis versus apicem evanescentibus. _Willdenow, Sp. Pl. vol. 2. p. 477._

LEAVES three nerved, oval-oblong, nerves vanishing towards the point of the leaf.

REFERENCE TO THE PLATE.

1. A flower spread open, shown from the outer side. 2. The same shown from the inner side. 3. The pointal.

* * * * *

For the first tolerable figure of the Cinnamon tree we are indebted to Dr. Hermann, Professor of Botany at Leyden who had also the honour of introducing it to Europe, having brought living plants with him, on his return from Ceylon, which vegetated in the Leyden Academy's garden, and in the gardens of Mynheers Benting and Beverning between two and three years, until a severe winter destroyed them. See his Catalogue of the Plants in the Leyden Garden (Horti Academici Lugduno-Batavi Catalogus), page 130, plates 665 and 666. This fact is the more curious, as Linnæus, describing the Cinnamon from dried specimens in his noble patron Clifford's collection, fifty years after, speaks of it as a plant forbidden to our shores; which Europe had never seen alive, and could hardly hope to see, or to retain even if it could be procured.

The Cinnamon was first cultivated in England by Mr. Miller in the Apothecaries' garden at Chelsea about the year 1768; who probably received it from Holland, the Spice plantations at that time being entirely in the hands of the Dutch. No figure of it has before been published in this country, nor any account of its flowering. It grows naturally in the Island of Ceylon, from whence the vast quantity annually imported into Europe is supplied. The following method of procuring and preparing the bark is abridged from Thunberg's Travels. Proper trees being selected, that is, those that are neither too young nor too old, the branches of three years growth are cut off with a pruning-knife, and their green outer bark scraped off with a crooked knife. The remaining bark is then ripped up lengthwise and peeled off and the smaller pieces being drawn into the larger, they are laid in the sun to dry. After being sufficiently dried, they are tied up in bundles of about 30 pounds weight each, and brought to the Company's storehouses, where inspectors appointed for that purpose examine every bundle by tasting of it; and on its being approved of, it is tied in bundles of about 85 pounds weight each, which are then sewed into double woollen sacks, over which black pepper is strewed to attract any remaining moisture, and in this state shipped for Europe. From the dust and fragments remaining in the warehouses the extremely valuable and rare oil of Cinnamon is distilled. An oil is also distilled from the leaves, another from the fruit, and a fourth from the bark of the root.

Cinnamon is also found wild in the woods of Martinico, according to Professor Jacquin; but the Ceylon Cinnamon is always considered the best.

We are informed by our friend Mr. Anderson, that a Cinnamon tree in the garden of the Bishop of Winchester at Farnham Castle (perhaps the finest in England) has for many years blossomed and ripened its fruit annually, and that great numbers of young trees have been raised from the fruit, which have far surpassed for healthiness and hardiness the plants commonly obtained from layers, or those imported; and which leads us to hope that the Cinnamon trees may soon become more common and less difficult of cultivation: and his lordship's great success with it will, we hope, serve to stimulate others. We have also seen a drawing in Mr. Lambert's collection, taken in the Bishop of Durham's garden at Mongewell, where it flowered, as we are informed by his lordship, in February 1796.

The Cinnamon tree requires to be kept in the bark-bed in the stove, and is propagated by cuttings and layers.

Our drawing was made in the month of February at J. Knight’s nursery, King’s Road, from a fine plant upwards of three feet high.

[Illustration]

PLATE DCXVII.

TROPÆOLUM PEREGRINUM.

The Little Bird Plant.

CLASS VIII. ORDER I.

OCTANDRIA MONOGYNIA. Eight Stamens. One Style.

ESSENTIAL GENERIC CHARACTER.

CALYX monophyllus, calcaratus, quinquefidus. Petala duo ad quinque. Stigma trifidum, seu stigmata tria. Drupæ tres, siccæ, et monospermæ.

CUP of one leaf with a spur five-cleft. Petals two to five. Summits three, or summit three-cleft. Berries three, dry, and one-seeded.

SPECIFIC CHARACTER.

TROPÆOLUM petalis serrato-incisis, duobus maximis, tribus minimis. _Jacq. Hort. Schœnb. 1. p. 51. tab. 98._

TROPÆOLUM with the petals tooth-gashed, two much larger than the rest; three very small.

REFERENCE TO THE PLATE.

1. Chives and pointal. 2. Seed-bud and pointal, summit magnified.

* * * * *

The Tropæolum peregrinum grows naturally in Peru, and was gathered wild by the French naturalist Feuillée near the town of Lima. The native name, according to that author, is Malla; the Spaniards call it Paxarito, which signifies a little bird; from the resemblance the expanded blossoms have to little humming-birds flying. Attaching itself by the long footstalks of the leaves to the branches, the plant often ascends to the very summits of trees in its native soil; and Professor Jacquin, director of the Emperor of Germany’s gardens at Schœnbrunn, informs us (in the work above quoted) that it grew there in the open ground to twenty-six feet in length, with a stem of a finger’s thickness, and a great many branches, but produced no flowers until transplanted into the green-house. A. B. Lambert, esq. who communicated the specimen from his gardens at Boyton last November, informs us that he cultivated it in a three-light melon-frame, which it completely filled, branching in all directions, and producing almost innumerable blossoms. The seeds but rarely ripen in this country, and are generally imported from Spain or Portugal. The plant, however, may be propagated by cuttings. Besides the five species of Tropæolum enumerated in the edition of the Species Plantarum by Willdenow, and the new species in our last volume (T. pennatum), three more species are described and figured in the Flora Peruviana of Ruiz and Pavon; some of which, and others of the many beautiful flowers of that country, the great intercourse now carried on with South America gives us to hope that we may soon see. One of the species in the Flora Peruviana having only two petals, has obliged us to make a little alteration in the generic character.

[Illustration]

PLATE DXCVIII.

BÆCKIA VIRGATA.

Twiggy Bæckia.

CLASS VIII. ORDER I.

OCTANDRIA MONOGYNIA. Eight Chives. One Pointal.

ESSENTIAL GENERIC CHARACTER.

CALYX 5-dentatus. Corolla 5-petala. Capsula 3-seu 4-locularis, polysperma, calyce tecta.

CUP 5-toothed. Blossom of 5 petals. Fruit 3-or 4-celled, many-seeded, covered by the cup.

SPECIFIC CHARACTER.

BÆCKIA foliis lineari-lanceolatis pellucido-punctatis, pedunculis axillaribus umbelliferis.

Leptospermum virgatum. _Forster._

BÆCKIA with linear-lanced leaves with transparent dots; the flowerstalks axillary, and bearing umbels.

REFERENCE TO THE PLATE.

1. A petal. 2. The chives and pointal. 3. The same shown from the under side.

* * * * *

In the Island of New Caledonia, celebrated by Captain Cook (above all others) for the courteous, friendly, and honest disposition of the men, and the inflexible virtue of the females, (see his Second Voyage, vol. ii. p. 105 to 127.) and whence every day brought them something new in natural history, this plant with many others was discovered by the two Forsters, who accompanied him as naturalists, and is published in their Genera of Plants gathered in the Islands of the South Seas as a species of Leptospermum. Dr. Smith, however, justly observes, that neither the number of stamens, the fruit, nor the opposite leaves, agree at all with that genus, but most naturally with the Linnean genus Bæckia, of which several species have lately been found in New Holland. The stamens vary from eight to ten; the germen three-celled, with about sixteen seeds in each; but how many of these ripen we have had no opportunity of observing. The leaves are not absolutely without nerves, as described by Forster; we find them faintly three-nerved in his own specimen, but they are more conspicuously so after they become dry, particularly on the under side. In the specimens with which we have been favoured by Mr. Milne from Fonthill, the leaves are a little smaller than those upon the original specimen, which may be occasioned by this plant's being yet so young, being raised only three years ago in the collection of the Marquis of Bath. The time of flowering is October. The Leptospermum virgatum of Willdenow we cannot quote, his descriptions being from two plants of very different genera jumbled together into one species.

* * * * *

In the 277th Number of The Botanical Magazine the writer, endeavouring to destroy the authority of the figure of Yucca gloriosa in The Botanist's Repository, vol. vii., and establish that of his own as the first, says that our figure cannot belong to that plant, in which "the trunk reaches only from six inches to two feet (Miller says in his Dictionary, from two feet and a half to three feet!) in height, and where the leaves are quite entire; but to Y. aloifolia, whose trunk reaches from 6 to 10 feet in height, and the leaves have a finely crenulate edging." Our drawing was taken at Lord Boston's from a plant only ten feet high, the stem little more than three, and the leaves not in the least crenated! The panicle in our figure is also said to be much closer than in that, with its branches likewise more lax and drooping. With all these contradictory qualities, however, it very much resembles Barreliere's figure of the same, which the writer himself has quoted, and in which the curvature of the buds, which he holds to be so extraordinary, is also conspicuous. No less curious is his objection to the tinge of purple on the flowers. Could it be possible that he had not seen either the plant that he way describing or the drawing of it? (See the figure in The Botanical Magazine.) But we leave the Yuccas to speak for themselves. The filamentosa he has also complimented with five feet of a stem (Botanical Magazine, No. 900), and quoted Micham's authority for it, although that author expressly says that it is stemless!

[Illustration]

PLATE DXCIX.

CHAMÆROPS HUMILIS.

Dwarf Fan-Palm.

CLASS XXIII. ORDER II.

POLYGAMIA DIŒCIA. Stamens and Pointals on different Plants, with some perfect Flowers occasionally.

GENERIC CHARACTER.

MASC. Calyx 3-partitus. Corolla 3-petala. Stamina 6.

HERMAPH. Calyx, corolla et stamina ut in masculis. Styli 3. Drupæ 3, monospermæ.

MALES. Cup 3-parted. Blossom 3-petalled. Stamens 6.

HERMAPHRODITES. Cup, blossom and stamens as in the males. Styles 3. Berries 3, dry, one-seeded.

SPECIFIC CHARACTER.

CHAMÆROPS frondibus palmatis, stipitibus spinosis, spathâ simplici. _Willd. Sp. Pl. 4. p. 1154._

CHAMÆROPS with palmate boughs, prickly footstalks, and simple sheaths.

REFERENCE TO THE PLATE.

1. Empalement and blossom. 2. The same shown from the outer side. 3. The chives.

* * * * *

The Dwarf Fan-Palm is the only species indigenous to Europe, where it grows naturally in Italy on the coast of Etruria, in the Island of Sicily, and in Spain in the province of Valencia, where we are informed by Cavanilles, in his Icones Plantarum, (vol. ii. p. 12.) it is most commonly found stemless, and in that tract called Desierto de las Palmas, or the Desert of Palms, with stems rarely exceeding two feet in height. In the district of Xabea, however, on the coast of the Mediterranean, he found many with stems fourteen feet high, and one as high as thirty feet. The same author informs us that the lower part of the stem, which enters the earth, and the heads of young blossoms before they burst from the sheath, are eaten by the Spaniards, to whom also the leaves are of the greatest utility, furnishing them with mats, ropes, brooms, and baskets, in the manufacture of which boys are principally employed, and women during the evenings in winter. Many of our fair countrywomen, we fear, spend their evenings less usefully. Professor Pontedera, in his Anthologia, published at Padua in 1720, has given three good plates of the Chamærops and its fructification, taken from a plant, the stem of which was twelve feet high, growing in the public garden there. From this author we learn that the young shoots or suckers from the bottom of the plant (called there cefaglioni) are eaten by the Italians. The Chamærops also grows spontaneously upon uncultivated hills on the coast of Barbary, where the lower part of the young stems and the roots are also eaten by the Moors; and the leaves, after being macerated in water, made into mats, ropes, baskets, &c., as in Spain. (See Desfontaines' Flora Atlantica, vol. iii. p. 473.) Willdenow takes notice of two varieties of the Chamærops, one of which is nearly stemless, and the other twenty feet in height; and the former of which is probably that cultivated in England, as we have never met with any of a large size, although the plant has been in our gardens since the year 1731; while that in the Jardin des Plantes at Paris, (nearly twenty feet high,) mentioned by Chevalier Lamarck in the Encyclopédie Méthodique, seems to be the second variety. Our drawing was taken early in March, in Malcolm's Nursery at Kensington, from a male plant about two feet in height with three fine bunches of male blossoms.

[Illustration]

PLATE DC.

GÆRTNERA RACEMOSA.

Racemed Gærtnera.

CLASS X. ORDER I.

DECANDRIA MONO-DI-TRIGYNIA. Ten Chives. One to Three Pointals.

GENERIC CHARACTER.

CALYX 5-partitus. Petala 5 lacero-ciliata, inæqualia. Stamina decem, unicum reliquis longius. Stylus incurvus. Stigma simplex. Germen triloculare, 3-spermum. Samara inæqualiter quadrialata, monosperma.

CUP five-parted. Petals five, cut-fringed, unequal. Stamens ten, one longer than the rest. Style incurved. Summit simple. Seed-bud of three cells with three seeds. Fruit with four unequal wings, one-seeded.

REFERENCE TO THE PLATE.

1. The empalement. 2. The same shown from the outer side. 3. The chives and pointals. 4. The seed-bud and pointals. 5. The capsule.

* * * * *

This curious and interesting plant, originally considered as a species of Banisteria by Linnæus, was very properly separated and named in honour of the celebrated Gærtner by Schreber in his Genera Plantarum; and Cavanilles nearly about the same time published it in his Ninth Dissertation, under the name of Molina, in honour of the author of the Natural History of Chili. Gærtnera however has the right of priority, and has been continued by Dr. Roxburgh in his Plants of the Coast of Coromandel, where he has given a figure and description of the plant, (vol. i. p. 19. tab. 18.) and by Willdenow in his edition of the Species Plantarum.

On examining the fructification, we have found the plant more closely allied to Banisteria than has hitherto been suspected, the styles being commonly two with a rudiment of a third, and the germen three-locular with a young seed in each cell; but the inequality of the petals and stamens, the solitary gland on the calyx, and the abortion of the lateral seeds, furnish abundant distinctions.

From the Coromandel plants above quoted we learn that it is a large climbing shrub, growing naturally on the Circar mountains in India, and is commonly cultivated all over that coast on account of the beauty and fragrance of its flowers, which open there during the rainy season. According to Linnæus it is also a native of the Island of Ceylon. No other species of the genus has yet been described. The plant is certainly a great acquisition to our collections, and was introduced from India by the late Lady Amelia Hume about the year 1805. Our specimen was communicated from the collection at Wormley Bury the end of last March.

[Illustration]

PLATE DCI.

CROTALARIA PULCHRA.

Fair Crotalaria.

CLASS XVII. ORDER IV.

DIADELPHIA DECANDRIA. Two Brotherhoods. Ten Stamens.

GENERIC CHARACTER.

LEGUMEN pedicellatum, turgidum. Filamenta connata cum figurâ dorsali.

POD on a footstalk, swollen. Filaments united into a tube, which is cleft at the back.

SPECIFIC CHARACTER.

CROTALARIA caule hirsuto; foliis simplicibus, elliptico-obovatis, integerrimis, sericeis, nitentibus; leguminibus calyce tectis bracteisque strigoso-sericeis.

CROTALARIA with a hairy stem; simple, elliptical, inversely oval, entire, silky, shining leaves: the pods, the calyx which covers them, and the bracts, all shining with silky hairs.

REFERENCE TO THE PLATE.

1. The empalement. 2. The standard. 3. One of the wings. 4. The keel. 5. Chives and pointal. 6. The seed-bud and pointal.

* * * * *

The choice collection of the late Lady Amelia Hume, at Wormley-bury, Herts, which before furnished us with the magnificent and unrivalled Pæonia papaveracea, has again produced us this new species of Crotalaria, seeds of which were received by her ladyship, about the year 1807, from the East Indies, under the name of C. pulcherrima, which we have abridged to pulchra, as we can hardly presume to say which species is most beautiful before we have seen the whole genus, which, from the large catalogue of Indian species by Dr. Roxburgh in his unpublished Indian Flora, a copy of which we have seen in the collection of A. B. Lambert, esq. (besides the forty-four species already published by Willdenow) we think is not soon likely to happen.

Crotalaria pulchra is as yet in very few collections in this country, nor have we heard of its blossoming in any other collection. The foreign specimens which we have seen with the Catalogue above mentioned in the same collection have very large spreading bunches of flowers, and there can be no doubt but the plants in this country, when a little stronger, will blossom with equal profusion. The plant is a native of the Mysore country in the East Indies. We received the specimen in the middle of March last.

[Illustration]

PLATE DCII.

GLYCINE COMPTONIANA.

Comptonian Glycine.

CLASS XVII. ORDER IV.

DIADELPHIA DECANDRIA. Two Brotherhoods. Ten Chives.

GENERIC CHARACTER.

CALYX bilabiatus. Corollæ carina apice vexillum reflectens.

CUP two-lipped. Keel of the blossom turning back the standard at the end.

SPECIFIC CHARACTER.

GLYCINE volubilis, foliis ternatis elongato-ovatis utrinque glabris, petiolis partialibus supra pubescentibus, racemis axillaribus multi-floris.

GLYCINE twining; the leaves by threes of a long egg-shape, smooth on both sides; the partial footstalks hairy above; the bunches lateral and many-flowered.

REFERENCE TO THE PLATE.

1. The empalement. 2. The standard. 3. One of the wings. 4. The keel. 5. Chives and pointal. 6. The seed-bud and pointal.

* * * * *

This elegant species is a native of New Holland, and belongs to that division of the genus with many-seeded pods without any partitions. We find in the germen the rudiments of eight kidneyshaped seeds, but the ripe fruit we have not seen. Having found no antecedent description or figure of the plant, we have named it in honour of Lady Northampton, in whose collection at Castle Ashby it flowered last April. But by whom it was introduced we are uncertain.

PLATE DCIII.

COMMERSONIA DASYPHYLLA.

Hairy-leaved Commersonia.

CLASS V. ORDER V.

PENTANDRIA PENTAGYNIA. Five Chives. Five Pointals.

GENERIC CHARACTER.

CALYX monophyllus 5-partitus. Petala 5 linearia basi sublobata, apice inflexa. Nectarium 5-partitum. Filamenta ad basin petalorum, brevissima. Germen subglobosum. Styli erecti. Stigmata capitata. Capsula dura, setosa, 5-locularis, 5-valvis, loculis 2-4-spermis.

EMPALEMENT of one leaf 5-parted. Petals 5, linear, commonly lobed at the base, turned in at the point. Nectary 5-parted. Threads at the base of the petals, very short. Seed-bud nearly round. Styles erect with their summits headed. Capsule hard, bristly, with 5 cells and 5 valves, the cells from 2-to 4-seeded.

SPECIFIC CHARACTER.

COMMERSONIA foliis elongato-cordatis inæqualiter serratis supra subtusque hirsutis.

COMMERSONIA with long heart-shaped unequally toothed leaves hairy on both sides.

REFERENCE TO THE PLATE.

1. Empalement, chives and pointals, magnified.

* * * * *

Commersonia dasyphylla is a low branching shrub, a native of New Holland or Van Diemen's Land, and is remarkable for a powerful odour of cucumbers which it emits when in blossom, and even retains for some time after it is dried. Being a plant which blossoms freely in early spring, and of very easy culture, it well deserves a place in the green-house or conservatory. Only one species of Commersonia has before flowered in England, the C. echinata of our last volume (Plate 519), but which has since been discovered to be a different species from the original C. echinata of Forster; which error we take the present opportunity of correcting, and beg of our readers to erase the name echinata in our 519th plate and description, and substitute platyphylla, with the following specific description:

COMMERSONIA platyphylla, foliis elongato-cordatis dentatis, supra stellato-hispidulis, subtus hirsutis, mollibus.

BROAD-LEAVED Commersonia with toothed leaves of a long heart-shape, a little rough with star-like bristles on the upper side; hairy and soft below.

Another nondescript Commersonia from Van Diemen's Land is now in our gardens, but has not yet blossomed; and we have seen dried specimens of a fifth species brought from New Holland by the late Governor King, in the collection of A. B. Lambert, esq.

We were favoured with the specimen of C. dasyphylla by Mr. Milne, from Fonthill, last April. The plant is at present in very few collections, and has not, we believe, yet blossomed anywhere else in England.

[Illustration]

PLATE DCIV.

MALPIGHIA POLYSTACHIA.

Branching Malpighia.

CLASS X. ORDER I. TO III.

DECANDRIA MONO-DI-TRIGYNIA. Ten Chives. One to Three Pointals.

GENERIC CHARACTER.

CALYX 5-phyllus basi extus poris binis melliferis. Petala 5 subrotunda, unguiculata. Filamenta basi cohærentia. Drupa 1-locularis tripyrena, nucibus monospermis.

CUP 5-leaved with two honey-bearing pores on the outside at the base. Petals five, nearly round with claws. Threads cohering at the base. Berry fleshy of one cell with three large bony seeds.

SPECIFIC CHARACTER.

MALPIGHIA foliis lanceolato-ovatis integerrimis glabris nitidis, subtus prope basin biglandulosis; racemis axillaribus et terminalibus; pedicellis uniglandulosis; floribus monogynis; stigmate capitato.

MALPIGHIA with lance-ovate, entire smooth shining leaves, with two glands on their underside near the base; bunches both from the sides and tops of the branches; flowerstalks with one gland; style one; stigma headed.

REFERENCE TO THE PLATE.

1. The empalement. 3. The chives spread open. 3. Seed-bud and pointals.

* * * * *

This splendid Malpighia is one of that fine collection of West Indian and American plants (we have before mentioned) made by Lord Seaforth when Governor of Barbadoes, and brought home with him on his return to England. From the catalogue of the collection we learn that the plant is a native of Trinidad, and his Lordship informs us that it was sent to him from that island by Mr. Thompson.

The species ought to be arranged between the M. nitida of Linnæus and M. glandulosa of Cavanilles, from both of which the glands on the leaf and solitary gland on the pedicel easily distinguish it. In the last circumstance, however, it agrees with the M. glandulosa of Jacquin, (see his Icones, tab. 469.) but is totally different both in the flowers and foliage. A. B. Lambert, esq., from whose stove at Boyton we were favoured with the specimen, informs us that it is a shrub of very free growth, throwing out long slender twigs on all sides, and requiring the frequent use of the knife to keep it in due bounds. The bunches of flowers first appeared in November, but did not open until the beginning of April. The leaf-stalks are thinly covered with silky bristles, some of which also appear towards the base of the younger leaves.

[Illustration]

PLATE DCV.

PELIOSANTHES TETA.

Bengal Peliosanthes, or Teta.

CLASS VI. ORDER I.

HEXANDRIA MONOGYNIA. Six Chives. One Pointal.

GENERIC CHARACTER.

CALYX nullus. Corolla 6-partita, subrotata, laciniis lato-ovatis obtusis. Nectarium corollâ triplò breviore incumbente, ore angustato integro. Stamina sub ore nectarii affixa. Filamenta subnulla. Stylus crassus, brevis, obtusè trigonus, trisulcatus. Stigma sulculus tripartitus in apice styli. Germen inferum, 3-loculare loculis dispermis. Semina (immatura) obovata, erecta, fundo loculamenti affixa. Fructus bacca? subovata, carnosa.

CUP none. Blossom 6-parted, nearly wheel-shaped, the divisions broadly egg-shaped, blunt. Nectary three times shorter than the blossom, leaning inwards, the mouth narrowed and entire. Stamens affixed under the lip of the nectary. Filaments scarcely any. Pointal fleshy, short, bluntly three-sided, with three furrows. Stigma a little three-branched channel on the top of the pointal. Germ below, of three cells which are two-seeded. Seeds (while young) inversely egg-shaped, erect, and affixed to the bottom of the cells. Fruit a berry? nearly oval, fleshy.

REFERENCE TO THE PLATE.

1. A segment of the flower magnified. 2. Seed-bud and pointal magnified, with the seeds exposed. 3. Seed-bud cut transversely, magnified.

* * * * *

This very curious plant, so distinct from every genus hitherto described, was introduced from the East Indies, at the same time with the Gærtnera figured in our last number, by the late Lady Amelia Hume. The roots are fibrous and perennial, as are also the leaves, which rise from the root upon footstalks embracing one another at the base, and are of a long lance-shape with strong longitudinal nerves, which are transversely interwoven with little branching veins. The flower-stalks are round, rising to from one to two feet in height, with membranaceous bracts scattered at regular distances, and were four in number in the specimen which we have figured. The blossoms grow in a kind of raceme formed of little bunches or tufts of two to four flowers each: the footstalks are of unequal lengths with a joint near the top, and are attended by incurved bracts at the base, the lowermost bract at each tuft being always the largest. The germ is nearly top-shaped, but a little hexangular upwards. Three of the divisions of the blossom are just perceptibly broader than the other three, and both the corolla and nectary are closely pierced with transparent dots hardly visible to the naked eye, but very distinct when magnified.

We have seen a very good coloured drawing of the plant taken in India in the collection of J. Fleming, esq. which represents the fruit (which has not yet ripened in England) as a bluntly oval, fleshy berry, with the seeds in pairs as in the germ. Both this drawing and the plant received from India by Lady Amelia Hume were marked _Teta viridiflora_; Teta being perhaps (if we may hazard a conjecture) the name applied to the plant by the native Indians. However this may be, as it appears to be known in India by that name, we have retained it for the specific designation; applying to the genus, in conformity to the Linnæan canons, (from πελιος, lividus, and ανθς, flos,) the name of Peliosanthes. Our drawing represents the original plant imported from India, with which we were favoured by Sir Abraham Hume, bart. last April, through the kindness of A. B. Lambert, esq. who has also informed us, from Dr. Roxburgh's MSS. in his possession, that the plant is found growing naturally about Chittagong in the East Indies. We have just seen two other species of the genus in the curious collection of T. Evans, esq. at Stepney, imported by him last Autumn from Prince of Wales's Island, of which they are natives. One of them has the leaves nearly of a blue colour; and Mr. Evans's collector informs us, that he found five or six species growing naturally in the island above mentioned, although he had not the good fortune to bring them alive to England.

Linnæus was of opinion, that there were not above ten thousand plants in the world; but above five-and-twenty thousand have already been described, and ten thousand probably yet remain to be added to the number!

[Illustration]

PLATE DCVI.

ZIERIA SMITHII.

Smithian Zieria.

CLASS IV. ORDER I.

TETRANDRIA MONOGYNIA. Four Chives. One Pointal.

GENERIC CHARACTER.

CALYX quadripartitus. Petala quatuor. Stamina glabra, glandulis insidentia. Stylus simplex. Stigma subquadrilobum. Capsulæ quatuor coalitæ. Semina arillata.

CUP four-parted. Petals four. Chives smooth, sitting on glands. Pointal simple. Summit generally four-lobed. Fruit of four cohering capsules. Seeds covered with an arillus.

REFERENCE TO THE PLATE.

1. Empalement magnified. 2. Chives and pointal. 3. A chive magnified. 4. The same shown from the outer side. 5. Empalement, seed-bud, and pointal magnified.

* * * * *

The Zieria Smithii is a dwarf warty shrub with opposite branches, and leaves which are composed of three lanceolate leaflets, rough with transparent dots, which probably secrete an oil, as the bruised leaves are very fragrant. A few small scattered hairs are just visible on their upper surface. The panicles of flowers rise from the axils of the leaves, which they often excel in length, and branch in the same opposite manner as the stem, with linear bracts at the divisions. The cups are very short, finely haired and dotted as the leaves. The petals are broad-lanced, pointed, and slightly tinged with purple on the outside. The genus was established by Dr. Smith in the fourth volume of the Linnean Society's Transactions, and named in memory of his friend Mr. Zier, whom he calls "an indefatigable botanist, but whose labours generally gained celebrity under another name than his own." Were celebrity only to be gained by real merit, many of the high-sounding names that now swell the trump of fame would, we fear, have far less pretensions than Zier. The Zieria Smithii was communicated last April by A. B. Lambert, esq. from his collection, and we have seen dried specimens of four other species preserved in his Herbarium, all (like the present) natives of New Holland, and agreeing in their shrubby nature, opposite branches, ternate leaves, and axillary bunches of flowers. None of the species have before been published.

[Illustration]

PLATE DCVII.

CLERODENDRUM TOMENTOSUM.

Downy Clerodendrum.

CLASS XII. ORDER II.

DIDYNAMIA ANGIOSPERMIA. Two Chives longer. Seeds covered.

GENERIC CHARACTER.

CALYX campanulatus, quinquefidus. Corolla tubo elongato, limbo quinquepartito, æquali. Stamina exserta. Germen quadriloculare, loculis monospermis. Drupa tetrapyrena.

CUP bell-shaped, five-cleft. Tube of the blossom elongated, with the limb equally five-parted. Stamens longer than the tube. Seed-bud four-celled, the cells one-seeded. Fruit a dry berry including four nuts.

SPECIFIC CHARACTER.

CLERODENDRUM tomentosum, foliis ellipticis acutis integris calycibusque tomentosis; corymbis congestis.--_Brown. Prodromus Floræ Novæ Hollandiæ et Insulæ Van Diemen, vol. 1. p. 510._

DOWNY Clerodendrum with elliptic acute entire leaves downy as well as the cups; corymbs crowded.

REFERENCE TO THE PLATE.

1. Empalement. 2. A blossom spread open. 3. Seed-bud and pointal. 4. A ripe fruit.

* * * * *

The Clerodendrum tomentosum is found naturally growing about Port Jackson and some other parts of the eastern and northern coasts of New Holland, according to Mr. Brown's Prodromus of the Flora of that country, just published. This long expected and interesting work contains descriptions of about two thousand plants, (of which, scarcely a third part have before been published) in the first volume, and the second is now in the press.

Although the Clerodendrum tomentosum has been in England above ten years, no figure of it has before been given in this country. All the plants which we have seen of it form erect shrubs from four to six feet in height. The time of blossoming is March and April. We have been favoured with specimens in blossom from the botanic garden of the Company of Apothecaries at Chelsea, and with the ripe fruit from Sir Abraham Hume's collection at Wormley-bury, but are uncertain who first introduced it.

[Illustration]

PLATE DCVIII.

CITRUS NOBILIS.

Mandarin Orange.

CLASS XVIII. ORDER III.

POLYADELPHIA ICOSANDRIA. Many Sets of Chives. Threads from the Calyx or Receptacle.

GENERIC CHARACTER.

CALYX 5-dendatus. Corolla 5-petala. Stamina 20 in cylindrum passim connata. Stylus 1. Bacca 9-12-locularis, pulpâ vesiculari.

CUP five-toothed. Petals five. Stamens about twenty, generally united at the base. Shaft 1. Fruit 9-to 12-celled, the pulp variously divided.

SPECIFIC CHARACTER.

CITRUS petiolis sublinearibus, fructu latescente depresso.

CITRUS with nearly linear leafstalks; the fruit broad depressed.

CITRUS nobilis, inermis, ramis adscendentibus: petiolis strictis, fructu tuberculoso subcompresso.--_Lour. Flor. Cochinchin. 2. p. 569?_

REFERENCE TO THE PLATE.

1. The empalement. 2. Chives and pointal. 3. The chives spread open, a tip magnified. 4. Seed-bud and pointal. 5. A horizontal section of the fruit.

* * * * *

The drawing of this remarkable Orange, which has so long been a desideratum in this country, was taken at Wormley-bury in the beginning of last May. The plant is a native of China, and Mr. Barrow informs us, that he found the fruit very common when on his travels in that country, and in much higher estimation than the common Orange by the Chinese, who call it Mandarin Orange (answering nearly to the English epithet of noble) by way of pre-eminence. The same gentleman also informs us, that he found some fine trees of it in the gardens at the Cape of Good Hope; it is therefore the more singular that it has been so long in reaching this country. From Loureiro’s description of his Citrus nobilis, there can be little doubt of its being intended for the Mandarin Orange; which, he informs us, grows to a moderately sized tree, and particularly notices the superior excellence and the depression of the fruit, whose common size is about five inches across. The plant at Sir Abraham Hume’s is as yet only about five feet in height, and was imported from Canton in 1805.

It is easily distinguished from the common Orange, both by its curious form and internal structure, the pulp adhering so loosely to the rind as to be separable from it by the slightest effort, and leaving in many places a considerable opening between them.

WONDERS of the WORLD.]

THE

WONDERS OF THE WORLD:

A

COMPLETE MUSEUM, DESCRIPTIVE AND PICTORIAL,

OF THE

WONDERFUL PHENOMENA AND RESULTS

OF

NATURE, SCIENCE AND ART.

BY

JOHN LORAINE ABBOTT.

ILLUSTRATED FROM ORIGINAL DESIGNS BY BILLINGS AND OTHERS.

=Hartford:= PUBLISHED BY CASE, TIFFANY AND COMPANY. 1856.

Entered according to Act of Congress, in the year 1855, by CASE, TIFFANY AND COMPANY, in the Clerk’s Office of the District Court of Connecticut.

PREFACE.

The _ancients_ boasted of their SEVEN WONDERS OF THE WORLD. These were the Pyramids of Egypt, the Colossus of Rhodes, the Aqueducts of Rome, the Labyrinth on the banks of the Nile, the Pharos of Alexandria, the Walls of Babylon, and the temple of Diana at Ephesus. But the WONDERS known to those of the _present_ day, may be counted by hundreds: wonders of Nature, wonders of Science, wonders of Art, and Miscellaneous wonders; each department full, to overflowing, of themes of the richest instruction and deepest interest.

To present some of the most striking of these wonders, in a manner that shall be acceptable to the man of science and profound research, and at the same time full of interest to the general reader, and the family at the fireside, has been the aim of the editor of the following pages. The exaggerated and marvelous stories which the mischievous fancy of travelers has too often imposed on the credulity of the weak, as well as the foolish fables founded in bigotry and superstition, which were too often received as truths in the dark ages, have been carefully avoided, and, where the narrative permitted, exposed; and nothing has been brought forward that has not been confirmed by the concurrent testimony of enlightened travelers, and men of science, and extended observation. On the subjects in which Nature, in her various departments, displays her most wondrous magnificence and beauty; or in those in which Science and Art have sought out their most wondrous inventions, and wrought out the most wondrous results, the best authorities have been carefully consulted. And the endeavor has been, so to assemble and arrange the multiplied objects of wonder and delight, as to confer a lasting benefit on the rising generation, and on families, and at the same time to present a work that shall commend itself to those whose lives have been wholly devoted to researches among the sublime wonders of nature, science and art. Believing that the standard of general reading is constantly rising higher, and that the sphere of intellectual tastes and pursuits is constantly growing wider, the writer has endeavored to prepare a volume that shall have more than the interest of fiction, and, at the same time, the ripe and rich instruction of the book of travels, or the work of science or descriptive art. The table of contents makes manifest how extensive the range of the topics presented; while the list of engravings may show how profusely and richly the enterprise of the publishers has illustrated a work, which it is hoped may meet with universal acceptance.

THE

=Wonders of the World.=

MOUNTAINS.

“And lo! the mountains print the distant sky, And o’er their airy tops faint clouds are driven, So softly blending that the cheated eye, Forgets or which is earth, or which is heaven!”—FAY.

“Mountains and all hills—let them praise the name of the Lord, for his name alone is excellent; his glory is above the earth and heaven.”—DAVID.

Among the _wonders_, or uncommon phenomena of the world, may be classed stupendous _mountains_. For though compared with the entire diameter of the earth, the highest elevations on its surface are no more than the inequalities on the skin of the orange to the orange itself, yet to our eyes they often appear immensely lofty and sublime. Descriptions of such vast and striking objects often fail to excite corresponding ideas; so that however accurate or poetical may be the accounts of this class of the prodigies of nature, no just notions of their vastness can be conveyed, by any written or graphical representation. The magnitude of an object must be seen to be duly conceived; and the mountain-wonders of the world will best be understood and felt by those who have visited Wales, Scotland, Switzerland, or the mountainous regions of America or Asia.

THE ANDES.

Some of the loftiest and most extensive mountains in the world, are the Andes, in South America. These stupendous hills, called by the Spaniards the =Cordilleras=, (from the word _cord_ or _chain_,) =i. e.=, the chains of the Andes, stretch north and south near the western coast, from the isthmus of Darien, through the whole of the continent of South America, to the straits of Magellan. In the north, there are three chains of separate ridges; but in advancing from Popayan toward the south, the three chains unite into a

single group, which is continued far beyond the equator. In Equador, near Quito, the more elevated summits of this group are ranged in two rows, (as seen in the cut below,) which form a double crest to the Cordilleras. The extent of the Andes mountains is not less than four thousand three hundred miles, from one end to the other.

[Illustration: THE CORDILLERAS, OR ANDES, NEAR QUITO.]

“Rocks rich in gems, and mountains big with mines, That on the high equator ridgy rise, Whence many a bursting stream auriferous plays.”—THOMSON.

In this country, the operations of nature appear to have been carried on on a larger scale, and with a bolder hand, than elsewhere; and in consequence, the whole is distinguished by a peculiar magnificence. Even the plain of Quito, which may be considered as the base of the Andes, is more elevated above the sea than the summits of many European mountains. In different places the Andes rise more than one-third higher than the famous peak of Teneriffe, the highest land in the ancient hemisphere. Their cloud-enveloped summits, though exposed to the rays of the sun in the torrid zone, are covered with eternal snows, and below them the storm is seen to burst, and the exploring traveler hears the thunder roll, and sees the lightnings dart beneath his feet. Throughout the whole of the range of these extensive mountains, as far as they have been explored, there is a certain boundary, above which the snow never melts; which boundary, in the torrid zone, has been ascertained to be fourteen thousand, six hundred feet, or nearly three miles above the level of the sea.

The ascent to the plain of Quito, on which stands Chimborazo, Cotopaxi, Pichincha, &c., is thus described by Don Juan de Ulloa:

“The ruggedness of the road from Taraguaga, leading up the mountain, is not easily described. The declivity is so great, in some parts, that the mules can scarcely keep their footing; and, in others, the acclivity is equally difficult. The trouble of sending people before to mend the road, the pain arising from the many falls and bruises, and the being constantly wet to the skin, might be supported; but these inconveniences are augmented by the sight of such frightful precipices and deep abysses, as excite in the mind constant terror. The road, in some places, is so steep, and yet so narrow, that the mules are obliged to slide down without making any use whatever of their feet. On one side of the rider, in this situation, rises an eminence of many hundred yards; and, on the other, is an abyss of equal depth; so that, if he should give the least check to his mule, and destroy the equilibrium, both must inevitably perish.

“Having traveled nine days in this manner, slowly winding along the sides of the mountains, we began to find the whole country covered with a hoar-frost; and a hut, in which we reposed, had ice in it. At length, after a perilous journey of fifteen days, we arrived upon a plain, at the extremity of which stands the city of Quito, the capital of one of the most charming regions in the world. Here, in the center of the torrid zone, the heat is not only very tolerable, but, in some places, the cold is even painful. Here the inhabitants enjoy the temperature and advantages of perpetual spring; the fields being constantly covered with verdure, and enameled with flowers of the most lively colors. But although this beautiful region is more elevated than any other country in the world, and it employs so many days of painful journey in the ascent, it is itself overlooked by tremendous mountains, their sides being covered with snow, while their summits are flaming with volcanoes. These mountains seem piled one upon the other, and to rise, with great boldness, to an astonishing hight. However, at a determined point above the surface of the sea, the congelation is found at the same hight in all the mountains. Those parts which are not subject to a continual frost, have here and there growing upon them a species of rush, resembling the broom, but much softer and more flexible. Toward the extremity of the part where the rush grows, and the cold begins to increase, is found a vegetable with a round bulbous head. Higher still, the earth is bare of vegetation, and seems covered with eternal snow. The most remarkable of the Andes are the mountains of Chimborazo, Cotopaxi, and Pichincha.”

CHIMBORAZO.

This is the most lofty and majestic peak of the Andes, and has a circular summit. It is twenty-two thousand feet, or more than four miles high. On the shores of the ocean, after the long rains of winter, Chimborazo appears like a cloud in the horizon. It detaches itself from the neighboring summits, and raises its lofty head over the whole chain of the Andes. Travelers who have approached the summits of Mont Blanc and Mont Rose, are alone capable of feeling the effect of such vast, majestic, and solemn scenery.

The bulk of Chimborazo is so enormous, that the part which the eye embraces at once, near the limit of the snows, is twenty-two thousand, nine hundred and sixty-eight feet, or four miles and a third in breadth. The extreme rarity of the strata of air across which the summits of the Andes are seen, contributes greatly to the splendor of the snow and the magical effect of its reflection. Under the tropics, at a hight of sixteen thousand, four hundred feet, or upward of three miles, the azure vault of the heavens appears of an

indigo tint; while, in so pure and transparent an atmosphere, the outlines of the mountains seem to detach themselves from the sky, and produce an effect at once sublime, awful, and profoundly impressive.

With the exception of the loftiest of the Himalaya, in Asia, Chimborazo is the highest known mountain in the world. Humboldt, Bonpland, and Montufar, were persevering enough to approach within one thousand, six hundred feet of the summit of this mighty king of mountains. Being aided in their ascent by a train of volcanic rocks, destitute of snow, they thus attained the amazing hight of nearly four miles above the level of the sea; and the former of these naturalists is persuaded that they might have reached the highest summit, had it not been for the intervention of a great crevice, or gap, which they were unable to cross. They were, therefore, obliged to descend, after experiencing great inconveniences and many unpleasant sensations. For three or four days, even after their return into the plain, they were not free from sickness, and an uncomfortable feeling, owing, as they suppose, to the vast proportion of oxygen in the atmosphere above. Long before they reached the above surprising hight, they had been abandoned by their guides, the Indians, who had taken alarm and were fearful of their lives. So great was the fall of snow on their return, that they could scarcely recognize each other, and they all suffered dreadfully from the intenseness of the cold.

A great number of Spaniards formerly perished in crossing the vast and dangerous deserts which lie on the declivity of Chimborazo; being now, however, better acquainted with them, such misfortunes seldom occur, especially as very few take this route, unless there be a prospect of calm and serene weather.

COTOPAXI.

This mountain is the loftiest of those volcanoes of the Andes which, at recent epochs, have undergone eruptions. Notwithstanding it lies near the equator, its summits are covered with perpetual snows. The absolute hight of Cotopaxi is eighteen thousand, eight hundred and seventy-six feet, or three miles and a half; consequently it is two thousand, six hundred and twenty-two feet, or half a mile, higher than Vesuvius would be, were that mountain placed on the top of the peak of Teneriffe! Cotopaxi is the most mischievous of the volcanoes in the vicinity of Quito, and its explosions are the most frequent and disastrous. The masses of scoriæ, and the pieces of rock, thrown out of this volcano, cover a surface of several square leagues, and would form, were they heaped together, a prodigious mountain. In 1738, the flames of Cotopaxi rose three thousand feet, or upward of half a mile, above the brink of the crater. In 1744, the roarings of this volcano were heard at the distance of six hundred miles. On the fourth of April, 1768, the quantity of ashes ejected at the mouth of Cotopaxi was so great, that it was dark till three in the afternoon. The explosion which took place in 1803, was preceded by the sudden melting of the snows which covered the mountain. For twenty years before no smoke or vapor, that could be perceived, had issued from the crater; but in a single night the subterraneous fires became so active, that at sunrise the external walls of the cone, heated to a very considerable temperature, appeared naked, and of the dark color which is peculiar to vitrified scoriæ. “At the port of Guyaquil,” observes Humboldt, “fifty-two leagues distant in a straight line from the crater, we heard, day and night, the noise of this volcano, like continued discharges of a battery; and we distinguished these tremendous sounds even on the Pacific ocean.”

The form of Cotopaxi is the most beautiful and regular of the colossal summits of the high Andes. It is a perfect cone, which, covered with a perpetual layer of snow, shines with dazzling splendor at the setting of the sun, and detaches itself in the most picturesque manner from the azure vault above. This covering of snow conceals from the eye of the observer even the smallest inequalities of the soil; no point of rock, no stony mass, penetrating this coat of ice, or breaking the regularity of the figure of the cone.

PICHINCHA.

Though celebrated for its great hight, Pichincha is three thousand, eight hundred and forty-nine feet, or three-fourths of a mile, lower than the perpendicular elevation of Cotopaxi. It was formerly a volcano; but the mouth or crater on one of its sides is now covered with sand or calcined matter, so that at present neither smoke nor ashes issue from it.

When it was ascended by Don George Juan and Don Antonio de Ulloa, for the purpose of their astronomical observations, they found the cold on the top of this mountain extremely intense, the wind very violent, and the fog, or, in other words, the cloud, so thick, that objects at the distance of six or eight paces were scarcely discernible. On the air becoming clear, by the clouds descending nearer the earth, in such a manner as to surround the mountain on all sides to a vast distance, these clouds afforded a lively representation of the sea, in which the top of the mountain seemed to stand, like an island in the center.

“With aspect mild, and elevated eye, Behold him seated on a mount serene, Above the fogs of sense, and passion’s storm: All the black cares and tumults of this life, Like harmless thunders, breaking at his feet.”—YOUNG.

When the clouds descended, the astronomers heard the dreadful noise of tempests, which discharged themselves from them on the adjacent country. They saw the lightning issue from the clouds, and heard the thunder roll far beneath them. While the lower parts were thus involved in tempests of thunder and rain, they enjoyed a delightful serenity; the wind abated, the sky cleared, and the enlivening rays of the sun moderated the severity of the cold. But when the clouds rose, their density rendered respiration difficult: snow and hail fell continually, and the winds returned with such violence, that it was impossible to overcome the fear of being blown down the precipices, or of being buried by the accumulation of ice and snow, or by the enormous fragments of rocks which rolled around them. Every crevice in their hut was stopped, and though the hut was small, was crowded with inhabitants, and several lamps were constantly burning, the cold was so great, that each individual was obliged to have a chafing-dish of coals, and several men were employed every morning in removing the snow which had fallen during the night. Their feet were swollen, and they became so tender and sensible, that walking was attended with extreme pain; their hands also were covered with chilblains, and their lips were so swollen and chapped, that every motion in speaking brought blood.

MOUNT ETNA.

“Now under sulphurous Cuma’s sea-bound coast, And vast Sicilia, lies the shaggy breast Of snowy Etna, nurse of endless frost, The pillared prop of heaven, forever pressed: Forth from whose sulph’rous caverns issuing rise Pure liquid fountains of tempestuous fire, Which vail in ruddy mists the noonday skies, While wrapt in smoke the eddying flames aspire, Or gleaming through the night with hideous roar, Far o’er the redd’ning main huge rocky fragments pour.

“But he, Vulcanian monster, to the clouds The fiercest, hottest inundations throws, While, with the burthen of incumbent woods, And Etna’s gloomy cliffs o’erwhelmed he glows. There on his flinty bed outstretch’d he lies, Whose pointed rock his tossing carcass wounds; There with dismay he strikes beholding eyes, Or frights the distant ear with horrid sounds.”—WEST.

Mount Etna, one of the most majestic of all the volcanoes, which the ancients considered as one of the highest mountains in the world, and on the summit of which they believed that Deucalion and Pyrrha sought refuge, to save themselves from the universal deluge, is situated on the plain of Catania, in Sicily.

Its elevation above the level of the sea has been estimated at ten thousand, nine hundred and sixty-three feet, or upward of two miles. On clear days it is distinctly seen from Valetta, the capital of Malta, a distance of one hundred and fifty miles. It is incomparably the largest burning mountain in Europe. From its sides other mountains arise, which, in different ages, have been ejected in single masses from its enormous crater. The most extensive lavas of Vesuvius do not exceed seven miles in length, while those of Etna extend to fifteen, twenty, and some even to thirty miles. The crater of Etna is seldom less than a mile in circuit, and sometimes is two or three miles; but the circumference of the Vesuvian crater is never more than half a mile, even when widely distended, in its most destructive conflagrations. And, lastly, the earthquakes occasioned by these adjacent volcanoes, their eruptions, their showers of ignited stones, and the destruction and desolation which they create, are severally proportionate to their respective dimensions.

[Illustration: CRATER OF MOUNT ETNA.]

A journey up Etna is considered as an enterprise of importance, as well from the difficulty of the route, as from the distance, it being thirty miles from Catania to the summit of the mountain. Its gigantic bulk, its sublime elevation, and the extensive, varied, and grand prospects which are presented from its summit, have, however, induced the curious in every age to ascend and examine it; and not a few have transmitted, through the press, the observations which they have made during their arduous journey. From its vast base it rises like a pyramid to the perpendicular hight of two miles, by an acclivity nearly equal on all sides, forming with the horizon an angle of about fifteen degrees, which becomes greater on approaching the crater; but the inclination of the steepest part of the cone nowhere exceeds an angle of forty-five degrees. This prodigious volcano may be compared to a forge, which, in proportion to the violence of the fire, to the nature of the fossil matters on which it acts, and of the gases which urge and set it in motion, produces, destroys, and reproduces, a variety of forms; and of this, as of all active volcanoes, we may say in the language of Young,

“The dread volcano ministers to good; Its smothered flames might undermine the world Loud Etnas fulminate in love to man.”

The top of Etna being above the common region of vapors, the heavens, at this elevation, appear with an unusual splendor. Brydone and his company observed, as they ascended in the night, that the number of the stars seemed to be infinitely increased, and the light of each was brighter than usual. The whiteness of the milky way was like a pure flame which spread across the heavens; and, with the naked eye, they could observe clusters of stars which were invisible from below. They likewise noticed several of those meteors called falling stars, which appeared as much elevated here as when viewed from the plain beneath.

This single mountain contains an epitome of the different climates throughout the world, presenting at once all the seasons of the year, and all the varieties of produce. It is accordingly divided into three distinct zones or regions, which may be distinguished as the torrid, temperate, and frigid, but which are known by the names of the cultivated region, the woody or temperate region, and the frigid or desert region. The former of these extends through twelve miles of the ascent toward the summit, and is almost incredibly abundant in pastures and fruit-trees of every description. It is covered with towns, villages and monasteries; and the number of inhabitants spread over its surface is estimated at one hundred and twenty thousand. In ascending to the woody or temperate region, the scene changes; it is a new climate, a new creation. Below, the heat is suffocating; but here, the air is mild and fresh. The turf is covered with aromatic plants; and the gulfs, which formerly ejected torrents of fire, are changed into woody valleys. Nothing can be more picturesque than this; the inequality of the soil displaying every moment some variety of scene: here, the ash and flowering thorns form domes of verdure; and there, the chestnut-trees grow to an enormous size. The one called =castagno de cento cavilli=, according to Brydone and Glover, has a circumference of two hundred and four feet. Many of the oaks also are of a prodigious size. Mr. Swinburne measured one which had a circumference of twenty-eight feet. The last, or desert region, commences more than a mile above the level of the sea. The lower part is covered with snow in winter only; but on the upper half of this sterile district the snows continually lie.

[Illustration: THE “CASTAGNO DE CENTO CAVILLI,” OR GREAT CHESTNUT TREE OF MOUNT ETNA.]

The cone of Etna is, in a right line, about a mile in ascent. The crater is about a mile and a half in circumference; and from the inner part of this, a column of smoke constantly rises; while the liquid fiery matter may be seen rolling, rising and falling within. As to the vastness and beauty of the prospect from the summit of Etna, all writers agree that it is probably unsurpassed. M. Houel was there at sunrise, when the horizon was perfectly clear, and the coast of Calabria, as seen in the distance, appeared to the eye misty, and undistinguishable from the sea. The sky above was specked with the light floating clouds that are so often seen in that delightful climate before the rising of the sun; and in the calm silence all nature seemed waiting the coming of the orb of day. And very soon the promise thus given began to be fulfilled. In a short time a fiery radiance appeared in the east. The fleecy clouds were tinged with purple; the atmosphere became strongly illuminated, and, reflecting the rays of the sun, seemed to be filled with a bright refulgence of flame. Although the heavens were thus enlightened, the sea still retained its dark azure, and the fields and forests did not yet reflect the rays of the sun. The gradual rising of this luminary, however, soon diffused light over the hills which lie below the peak of Etna. This last stood like an island in the midst of the ocean, with luminous points multiplying every moment around, and spreading over a wider extent with the greatest rapidity. It was, he said, as if the world had been observed suddenly to spring from the night of non-existence.

“Ere the rising sun Shone o’er the deep, or ’mid the vault of night The moon her silver lamp suspended; ere The vales with springs were watered, or with groves Of oak or pine the ancient hills were crowned; Then the Great Spirit, whom his works adore, Within his own deep essence viewed the forms, The forms eternal of created things: The radiant sun; the moon’s nocturnal lamp; The mountains and the streams: the ample stores Of earth, of heaven, of nature. From the first, On that full scene his love divine he fixed, His admiration. Till, in time complete, What he admired and loved, his vital power Unfolded into being. Hence the breath Of life, informing each organic frame; Hence the green earth, and wild resounding waves; Hence light and shade, alternate; warmth and cold; And bright autumnal skies, and vernal showers, And all the fair variety of things.”—AKENSIDE.

The most sublime object, however, which the summit of Etna presents, is the immense mass of its own colossal body. Its upper region exhibits rough and craggy cliffs, rising perpendicularly, fearful to the view, and surrounded by an assemblage of fugitive clouds, to increase the wild variety of the scene. Amid the multitude of woods in the middle or temperate region, are numerous mountains, which, in any other situation, would appear of a gigantic size, but which, compared to Etna, are mere mole-hills. Lastly, the eye contemplates with admiration the lower region, the most extensive of the three, adorned with elegant villas and castles, verdant hills and flowery fields, and terminated by the extensive coast, where to the south stands the beautiful city of Catania, to which the waves of the neighboring sea serve as a mirror.

Etna has been celebrated as a volcano from the remotest antiquity. Eruptions are recorded by Diodorus Siculus, as having happened five hundred years before the Trojan war, or sixteen hundred and ninety-three years before the Christian era.

“Etna roars with dreadful ruins nigh, Now hurls a bursting cloud of cinders high, Involved in smoky whirlwinds to the sky; With loud displosion to the starry frame, Shoots fiery globes, and furious floods of flame: Now from her bellowing caverns burst away Vast piles of melted rocks in open day. Her shattered entrails wide the mountain throws, And deep as hell her flaming center glows.”—WARTON.

In 1669, the torrent of burning lava inundated a space fourteen miles in length, and four in breadth, burying beneath it part of Catania, till at length it precipitated itself into the sea. For several months before the lava broke out, the old mouth, or great crater of the summit, was observed to send forth much smoke and flame, and the top had fallen in, so that the mountain was much lowered.

Eighteen days before, the sky was very thick and dark, with thunder, lightning, frequent concussions of the earth, and dreadful subterraneous bellowings. On the eleventh of March, about sunset, an immense gulf opened in the mountain, into which when stones were thrown, they could not be heard to strike the bottom. Ignited rocks, fifteen feet in length, were hurled to the distance of a mile; while others of a smaller size were carried three miles. During the night, the red-hot lava burst out of a vineyard twenty miles below the great crater, and ascended into the air to a considerable hight. In its course, it destroyed five thousand habitations, and filled up a lake several fathoms deep. It shortly after reached Catania, rose over the walls, whence it ran for a considerable length into the sea, forming a safe and beautiful harbor, which was, however, soon filled up by a similar torrent of inflamed matter. This is the stream, the hideous deformity of which, devoid of vegetation, still disfigures the south and western borders of Catania, and on which part of the noble modern city is built.

The showers of scoriæ and sand which, after a lapse of two days, followed this eruption, formed a mountain called Monte Rosso, having a base of about two miles, and a perpendicular hight of seven hundred and fifty feet. On the twenty-fifth, the whole mountain, even to the most elevated peak, was agitated by a tremendous earthquake. The highest crater of Etna, which was one of the loftiest parts of the mountain, then sunk into the volcanic gulf, and in the place which it had occupied, there now appeared nothing but a wide gulf, more than a mile in extent, from which issued enormous quantities of smoke, ashes and stones.

In 1809, twelve new craters opened about half-way down the mountain, and threw out rivers of burning lava, by which several estates were covered to the depth of thirty or forty feet; and during three or four successive nights, a very large river of red-hot lava was distinctly seen, in its whole extent, running down from the mountain.

In 1811, several mouths opened on the eastern side of the mountain: being nearly in the same line, and at equal distances, they presented to the view a striking spectacle; torrents of burning matter, discharged with the greatest force from the interior of the volcano, illuminated the horizon to a great extent. An immense quantity of matter, which was driven to considerable distances, was discharged from these apertures, the largest of which continued for several months to emit torrents of fire. Even at the time when it had the appearance of being choked, there suddenly issued from it clouds of ashes, which descended, in the form of rain, on the city of Catania and its environs, as well as on the fields situated at a very considerable distance. A roaring, resembling that of a sea in the midst of a tempest, was heard to proceed from the interior of the mountain; and this sound, accompanied from time to time by dreadful explosions, resembling thunder, reëchoed through the valleys, and spread terror on every side.

MOUNT VESUVIUS.

“The fluid lake that works below, Bitumen, sulphur, salt, and iron scum, Heaves up its boiling tide. The lab’ring mount Is torn with agonizing throes. At once, Forth from its sides disparted, blazing pours A mighty river; burning in prone waves, That glimmer through the night, to yonder plain. Divided there, a hundred torrent streams, Each plowing up its bed, roll dreadful on, Resistless. Villages, and woods, and rocks, Fall flat before their sweep. The region round, Where myrtle-walks and groves of golden fruit Rose fair; where harvest wav’d in all its pride; And where the vineyard spread its purple store, Maturing into nectar; now despoiled Of herb, leaf, fruit and flower, from end to end Lies buried under fire, a glowing sea!”—MALLET.

This celebrated volcano, which has for so many ages attracted the attention of mankind, and the desolating eruptions of which have been so often and so fatally experienced, is distant, in an eastern direction, about seven miles from Naples. It rises, insulated, upon a vast and well cultivated plain, presenting two summits on the same base, in which particular it resembles Mount Parnassus. One of these, La Somma, is generally agreed to have been the Vesuvius of Strabo and the ancients; the other, having the greatest elevation, is the mouth of the volcano, which almost constantly emits smoke. Its hight above the level of the sea, is thirty-nine

hundred feet, and it may be ascended by three different routes, which are all very steep and difficult, from the conical form of the mountain, and the loose ashes which slip from under the feet: still, from the base to the summit, the distance is not more than three Italian miles. The circumference of the platform on the top, is five thousand and twenty-four feet, or nearly a mile. Thence may be seen Portici, Capræa, Ischia, Pausilippo, and the whole coast of the gulf of Naples, bordered with orange-trees: the prospect is that of Paradise seen from the infernal regions.

[Illustration: MOUNT VESUVIUS.]

On approaching the mountain, its aspect does not convey any impression of terror, nor is it gloomy, being cultivated for more than two-thirds of its hight, and having its brown top alone barren. There all verdure ceases; yet, when it appears covered with clouds, which sometimes encompass its middle only, this circumstance rather adds to than detracts from the magnificence of the spectacle. Upon the lavas which the volcano long ago ejected, and which, like great furrows, extend into the plain and to the sea, are built houses, villages and towns. Gardens, vineyards and cultivated fields surround them; but a sentiment of sorrow, blended with apprehensions about the future, arises on the recollection that, beneath a soil so fruitful and so smiling, lie edifices, gardens and whole towns swallowed up. Portici rests upon Herculaneum; its environs upon Resina; and at a little distance is Pompeii, in the streets of which, after more than seventeen centuries of non-existence, the astonished traveler now walks. After a long interval of repose, in the first year of the reign of Titus, (the seventy-ninth of the Christian era,) the volcano suddenly broke out, ejecting thick clouds of ashes and pumice-stones, beneath which Herculaneum, Stabia and Pompeii were completely buried. This eruption was fatal to the elder Pliny, the historian, who fell a victim to his humanity and love of science. Even at this day, in speaking of Vesuvius, the remembrance of his untimely death excites a melancholy regret. All the coast to the east of the gulf of Naples was, on the above occasion, ravaged and destroyed, presenting nothing but a long succession of ejected matters from Herculaneum to Stabia. The destruction did not extend to the western part, but stopped at Naples, which suffered comparatively little.

Thirty-eight eruptions of Vesuvius are recorded in history up to the year 1806. That of 1779, has been described by Sir William Hamilton, as among the most remarkable, from its extraordinary and terrific appearance. During the whole of July, the mountain was in a state of considerable fermentation, subterraneous explosions and rumbling noises being heard, and quantities of smoke thrown up with great violence, sometimes with red-hot stones, scoriæ, and ashes. On the fifth of August, the volcano was greatly agitated, a white sulphurous smoke, apparently four times the hight and size of the volcano itself, issuing from the crater, at the same time that vast quantities of stones, &c., were thrown up to the supposed hight of two thousand feet. The liquid lava, having cleared the rim of the crater, flowed down the sides of the mountain to the distance of four miles. The air was darkened by showers of reddish ashes, blended with long filaments of a vitrified matter resembling glass.

On the seventh, at midnight, a fountain of fire shot up from the crater to an incredible hight, casting so bright a light, that the smallest objects were clearly distinguishable at any place within six miles of the volcano. On the following evening, after a tremendous explosion, which broke the windows of the houses at Portici, another fountain of liquid fire rose to the surprising hight of ten thousand feet, (nearly two miles,) while puffs of the blackest smoke accompanied the red-hot lava, interrupting its splendid brightness here and there by patches of the darkest hue. The lava was partly directed by the wind toward Ottaiano, on which so thick a shower of ashes, blended with vast pieces of scoriæ, fell, that had it been of longer continuance, that town would have shared the fate of Pompeii. It took fire in several places; and had there been much wind, the inhabitants would have been burned in their houses, it being impossible for them to stir out. To add to the horror of the scene, incessant volcanic lightning darted through the black cloud that surrounded them, while the sulphureous smell and heat would scarcely allow them to draw their breath. In this dreadful state they remained nearly half an hour. The remaining part of the lava, still red-hot and liquid, fell on the top of Vesuvius, and covered its whole cone, together with that of La Somma, and the valley between them, thus forming one complete body of fire, which could not be less than two miles and a half in breadth, and casting a heat to the distance of at least six miles around.

The eruption of 1794 is accurately described by the above writer; but has not an equal degree of interest with the one cited above. We subjoin a few particulars, among which is a circumstance well deserving notice, as it leads to an estimate of the degree of heat in volcanoes. Sir William says that although the town of Torre del Greco was instantly surrounded with red-hot lava, the inhabitants saved themselves by coming out of the tops of their houses on the following day. It is evident, observes Mr. Kirwan, that if this lava had been hot enough to melt even the most fusible stones, these persons must have been suffocated.

This eruption happened on the fifteenth of June, at ten o’clock at night, and was announced by a shock of an earthquake, which was distinctly felt at Naples. At the same moment a fountain of bright fire, attended with a very black smoke and a loud report, was seen to issue, and rise to a considerable hight, from about the middle of the cone of Vesuvius. It was hastily succeeded by other

fountains, fifteen of which were counted, all in a direct line, tending for the space of about a mile and a half downward, toward the towns of Resina and Torre del Greco. This fiery scene, this great operation of nature, was accompanied by the loudest thunder, the incessant reports of which, like those of a numerous heavy artillery, were attended by a continued hollow murmur, similar to that of the roaring of the ocean during a violent storm. Another blowing noise resembled that of the ascent of a large flight of rockets. The houses at Naples were for several hours in a constant tremor, the doors and windows shaking and rattling incessantly, and the bells ringing. At this awful moment the sky, from a bright full moon and starlight, became obscured; the moon seemed eclipsed, and was soon lost in obscurity. The murmur of the prayers and lamentations of a numerous population, forming various processions, and parading the streets, added to the horrors of the scene.

On the following day a new mouth was opened on the opposite side of the mountain, facing the town of Ottaiano: from this aperture a considerable stream of lava issued, and ran with great velocity through a wood, which it burnt; but it stopped, after having run about three miles in a few hours, before it reached the vineyards and cultivated lands. The lava which had flowed from several new mouths on the south side of the mountain, reached the sea into which it ran, after having overwhelmed, burnt and destroyed the greater part of Torre del Greco, through the center of which it took its course. This town contained about eighteen thousand inhabitants, all of whom escaped, with the exception of about fifteen, who through age or infirmity, were overwhelmed in their houses by the lava. Its rapid progress was such, that their goods and effects were entirely abandoned.

It was ascertained some time after, that a considerable part of the crater had fallen in, so as to have given a great extension to the mouth of Vesuvius, which was conjectured to be nearly two miles in circumference. This sinking of the crater was chiefly on the west side, opposite Naples, and, in all probability, occurred early in the morning of the eighteenth, when a violent shock of an earthquake was felt at Resina, and other places situated at the foot of the volcano. The clouds of smoke which issued from the now widely extended mouth of Vesuvius, were of such a density as to appear to force their passage with the utmost difficulty. One cloud heaped itself on another, and, succeeding each other incessantly, they formed in a few hours such a gigantic and elevated column, of the darkest hue, over the mountain, as seemed to threaten Naples with immediate destruction, it having at one time been bent over the city, and appearing to be much too massive and ponderous to remain long suspended in the air.

From the above time, till 1804, Vesuvius remained in a state of almost constant tranquillity. Symptoms of a fresh eruption had manifested themselves for several months, when at length on the night of the eleventh of August, a deep roaring was heard at the hermitage of Salvador, and the places adjacent to the mountain, accompanied by shocks of an earthquake, which were sensibly felt at Resina. On the following morning, at noon, a thick black smoke rose from the mouth of the crater, which, dilating prodigiously, covered the whole volcano. In the evening, loud explosions were heard; and at Naples a column of fire was seen to rise from the aperture, carrying up stones in a state of complete ignition, which fell again into the crater. The noise by which these igneous explosions were accompanied, resembled the roaring of the most dreadful tempest and the whistling of the most furious winds; while the celerity with which the substances were ejected was such, that the first emission had not terminated when it was succeeded by a second. Small monticules were at this time formed of a fluid matter, resembling a vitreous paste of a red color, which flowed from the mouth of the crater; and these became more considerable in proportion as the matter accumulated.

In this state the eruption continued for several days, the fire being equally intense, with frequent and dreadful noises. On the twenty-eighth, amid these fearful symptoms, another aperture, ejecting fire and stones, situated behind the crater, was seen from Naples. The burning mass of lava which escaped from the crater on the following day, was distinguished from Torre del Greco, having the appearance of a vitreous fluid, and advancing toward the base of the mountain between the south and south-west. It reached the base on the thirtieth, having flowed from the aperture, in less than twenty-four hours, a distance of three thousand and fifty-three feet, while its mean breadth appeared to be about three hundred and fifty, but at the base, eight hundred and sixty feet. In its course it divided into four branches, and finally reached a spot called the Guide’s Retreat. Its entire progress to this point was more than a mile, so that, taking a mean proportion, this lava flowed at the rate of eighty-six feet an hour.

At the time of this eruption, Kotzebue was at Naples. Vesuvius lay opposite to his window, and when it was dark he could clearly perceive in what manner the masses of fire rolled down the mountain. As long as any glimmering of light remained, that part of the mountain was to be seen on the declivity of which the lava formed a straight but oblique line. As soon, however, as it was perfectly dark, and the mountain itself had vanished from the eye, it seemed as if a comet with a long tail stood in the sky. The spectacle was awful and grand!

Kotzebue ascended the mountain on the morning succeeding the opening of a new gulf, and approached the crater as nearly as prudence would allow. From its center ascended the sulphurous yellow cone which the eruption of this year had formed: on the

other side, a thick smoke perpetually arose from the abyss opened during the preceding night. The side of the crater opposite to him, which rose considerably higher than that on which he stood, afforded a singular aspect; for it was covered with little pillars of smoke, which burst forth from it, and had some resemblance to extinguished lights. The air over the crater was actually embodied, and was clearly to be seen in a tremulous motion. Below, the volcano boiled and roared dreadfully, like the most violent hurricane; but occasionally a sudden deadly stillness ensued for some moments, after which the roaring renewed with double vehemence, and the smoke burst forth in thicker and blacker clouds. It was, he observes, as if the spirit of the mountain had suddenly tried to stop the gulf, while the flames indignantly refused to endure the confinement.

It is remarkable, that the great eruption of 1805, happened on the twelfth of August, within a day of that of the preceding year. Subterraneous noises had been previously heard, and a general apprehension of some violent commotion prevailing, the inhabitants of Torre del Greco and Annunciada had left their homes, through the apprehension of a shower of fire and ashes, similar to that which buried Pompeii. The stream of lava took the same course with that of 1794, described above, one of the arms following the direction of the great road, and rolling toward the sea. The stream soon divided again, and spreading itself with an increased celerity, swept away many houses and the finest plantations. The other branch, at first, took the direction of Portici, which was threatened; but turning, and joining the preceding one, formed a sort of islet of boiling lava in the middle, both ending in the sea, and composing a promontory of volcanic matters. In the space of twenty minutes the whole extent of ground which the lava occupied was on fire, offering a terrible yet singular spectacle, as the burning trees presented the aspect of white flames, in contrast with those of the volcanic matters, which were red. The lava swept along with it enormous masses of whatever occurred in its course, and, on its reaching the sea, nothing was to be seen or heard for a great extent of shore, beside the boiling and hissing arising from the conflict of the water and fire.

It remains now to introduce a slight notice of the eruption of 1806, which, without any sensible indication, took place on the evening of the thirty-first of May, when a bright flame rose from the mountain to the hight of about six hundred feet, sinking and rising alternately, and affording so clear a light, that a letter might have been read at the distance of a league around the mountain. On the following morning, without any earthquake preceding, as had been customary, the volcano began to eject inflamed substances from three new mouths, pretty near to each other, and about six hundred and fifty feet from the summit. The lava took the direction of Torre del Greco and Annunciada, approaching Portici, on the road leading from Naples to Pompeii. Throughout the whole of the second of June, a noise was heard, resembling that of two armies engaged, when the discharges of artillery and musketry are very brisk. The current of lava now resembled a wall of glass in a state of fusion, sparks and flashes issuing from it from time to time, with a powerful detonation. Vines, trees, houses—whatever objects, in short, it encountered on its way, were instantly overthrown or destroyed. In one part, where it met with the resistance of a wall, it formed a cascade of fire. In a few days Portici, Resina, and Torre del Greco, were covered with ashes thrown out by the volcano; and on the ninth, the two former places were deluged with a thick black rain, consisting of a species of mud filled with sulphurous particles. On the first of July, the ancient crater had wholly disappeared, being filled with ashes and lava, and a new one was formed in the eastern part of the mountain, about six hundred feet in depth, and having about the same width at the opening. Several persons, on the above day, descended about half-way down this new mouth, and remained half an hour very near the flames, admiring the spectacle presented by the liquid lava, which bubbled up at the bottom of the crater, like the fused matter in a glass-house. This eruption continued until September, made great ravages, and was considered as one of the most terrible that had occurred in the memory of the inhabitants.

MOUNT HECLA.

[See cut, page 29.]

“Still pressing on beneath Tornea’s lake, And Hecla flaming through a waste of snow, And farthest Greenland, to the pole itself, Where, falling gradual, life at length goes out, The Muse expands her solitary flight; And hov’ring o’er the wide stupendous scene, Beholds new scenes beneath another sky. Throned in his palace of cerulean ice, Here Winter holds his unrejoicing court, And through his airy hall the loud misrule Of driving tempest is forever heard; Here the grim tyrant meditates his wrath; Here arms his winds with all-subduing frost, Molds his fierce hail, and treasures up his snows.”

On proceeding along the southern coast of Iceland, and at an inconsiderable distance from Skalholt, Mount Hecla, with its three summits, presents itself to the view. Its hight is five thousand feet, or nearly a mile above the level of the sea. It is not a promontory, but lies about four miles inland. It is neither so elevated nor so picturesque as several of the surrounding Icelandic mountains; but has been more noticed than many other volcanoes of an equal extent, partly through the frequency of its eruptions, and partly from its situation, which exposes it to the view of many ships sailing to Greenland and North America. The surrounding territory has been

so devastated by these eruptions, that it has been deserted.

“Vast regions dreary, bleak and bare! There on an icy mountain’s hight, Seen only by the moon’s pale light Stern Winter rears his giant form, His robe a mist, his life a storm: His frown the shiv’ring nations fly, And, hid for half the year, in smoky caverns lie.”

[Illustration: MOUNT HECLA AND THE GEYSERS.]

The natives assert that it is impossible to ascend the mountain, on account of the great number of dangerous bogs, which, according to them, are constantly emitting sulphurous flames and exhaling smoke; while the more elevated summit in the center is covered with boiling springs and large craters, which continually propel fire and smoke. To the south and west the environs present the most desolating results of frequent eruptions, the finest part of the territory being covered by torrents of melted stone, sand, ashes, and other volcanic matter; notwithstanding which, between the sinuosities of the lava in different parts, some portion of meadows, walls and broken hedges may be observed. The devastation is still greater on the north and east sides, which present dreadful traces of the ruin of the country and its habitations. Neither plants nor grass are to be met with to the extent of two leagues round the mountain, in consequence of the soil being covered with stones and lava; and in some parts, where the subterraneous fire has broken out a second time, or where the matter which was not entirely consumed has again become ignited, the fire has contributed to form small red and black hillocks and eminences, from scoriæ, pumice-stones and ashes. The nearer the mountain the larger are these hillocks, and there are some of them, the summits of which form a circular hollow, whence the subterraneous fire ejects the matter. On approaching Hecla the ground becomes almost impassable, particularly near the higher branches of lava thrown from the volcano. Round the latter is a mountain of lava, consisting of large fused stones, from forty to seventy feet high, and in the form of a rampart or wall. These stones are detached, and chiefly covered with moss; while between them are very deep holes, so that the ascent on the western side requires great circumspection. The rocks are completely reduced to pumice, dispersed in thin horizontal layers, and fractured in every direction, from which some idea may be formed of the intensity of the fire that has acted on them.

“There Winter, armed with terrors here unknown, Sits absolute on his unshaken throne; Piles up his stores amidst the frozen waste, And bids the mountains he has built stand fast; Beckons the legions of his storms away From happier scenes to make the land a prey; Proclaims the soil a conquest he has won, And scorns to share it with the distant sun.”

Sir Joseph Banks, Dr. Solander, Dr. James Lind, of Edinburgh, and Dr. Van Troil, a Swede, were the earliest adventurous travelers who ascended to the summit of Mount Hecla. This was in 1772; and the attempt was facilitated by a preceding eruption in 1766, which had greatly diminished the steepness and difficulty of the ascent. On their first landing, they found a tract of land sixty or seventy miles in extent, entirely ruined by lava, which appeared to have been in a state of complete liquefaction. To accomplish their undertaking, they had to travel from three hundred to three hundred and sixty miles over uninterrupted tracts of lava. In ascending, they were obliged to quit their horses at the first opening from which the fire had burst: a spot, which they describe as presenting lofty glazed walls and high glazed cliffs, differing from anything they had ever seen before. At another opening above, they fancied they discerned the effects of boiling water; and not far from thence, the mountain, with the exception of some bare spots, was covered with snow. The difference of aspect they soon perceived to be occasioned by the hot vapor ascending from the mountain. The higher they proceeded, the larger these spots became; and, about two hundred yards below the summit, a hole about a yard and a half in diameter, was observed, whence issued so hot a stream, that they could not measure the degree of heat with a thermometer. The cold now began to be very intense. Fahrenheit’s thermometer, which at the foot of the mountain was at fifty-four degrees, fell to twenty-four degrees; while the wind became so violent, that they were sometimes obliged to lie down, from a dread of being blown into the most dreadful precipices. On the summit itself they experienced, at one and the same time, a high degree of heat and cold; for, in the air, Fahrenheit’s thermometer constantly stood at twenty-four degrees, but when placed on the ground, it rose to one hundred and fifty-three degrees.

Messrs. Olafsen and Povelsen, two naturalists, whose travels in Iceland were undertaken by order of his Danish majesty, after a fatiguing journey up several small slopes, which occurred at intervals, and seven of which they had to pass, at length reached the summit of Mount Hecla at midnight. It was as light as at noonday, so that they had a view of an immense extent, but could perceive nothing but ice; neither fissures, streams of water, boiling springs, smoke, nor fire, were apparent. They surveyed the glaciers in the eastern part, and in the distance saw the high and square mountain of Hærdabreid, an ancient volcano, which appeared like a large castle.

Sir G. S. Mackenzie, in his travels in Iceland, ascended Mount Hecla; and from his account we extract the following interesting particulars. In proceeding to the southern extremity of the mountain, he descended, by a dangerous path, into a valley, having a small lake in one corner, and the opposite extremity bounded by a perpendicular face of rock, resembling, in its broken and rugged appearance, a stream of lava. While advancing, the sun suddenly broke through the clouds, and the brilliant reflection of his beams, from different parts of this supposed lava, as if from a surface of glass, delighted our traveler by the instantaneous conviction that he had now attained one of the principal objects connected with the plan of his expedition to Iceland. He hastened to the spot, and all his wishes were fully accomplished in the examination of an object which greatly exceeded the expectations he had formed. On ascending one of the abrupt pinnacles, which rose out of this extraordinary mass of rock, he beheld a region, the desolation of which can scarcely be paralleled. Fantastic groups of hills, craters, and lava, leading the eye to distant snow-crowned “jockuls,” (inferior mountains,) the mist rising from a waterfall; lakes, embosomed among bleak mountains; an awful profound silence; lowering clouds; marks all around of the furious action of the most destructive of elements; all combined to impress the soul with sensations of dread and wonder. The longer he and his companions contemplated this scene, the more unable they were to turn their eyes from it; and a considerable time elapsed before they could bring themselves to attend to the business which had tempted them to enter so frightful a district of the country.

Having proceeded a considerable distance along the edge of a stream of lava, a narrow part of which they crossed, they gained the foot of the south end of Mount Hecla. While, in ascending, they had to pass over rugged lava, they experienced no great difficulty in advancing; but when they reached the steepest part of the mountain, which was covered with loose slags, they sometimes lost at one step by the yielding of these, a space which had been gained by several.

Having passed a number of fissures, by leaping across some, and stepping along masses of slags which lay over others, they at length reached the summit of the first peak. The clouds now became so thick, that they began to despair of being able to proceed any further: it was, indeed, dangerous even to move; for the peak consists of a very narrow ridge of slags, not more than two feet broad, having a precipice on each side, several hundred feet in depth. One of these precipices forms the side of a vast hollow, which seems to have been one of the craters. At length the sky cleared a little, and enabled them to discover a ridge below, which seemed to connect the peak they had ascended with the middle or principal one. They lost no time in availing themselves of this opportunity, and, by balancing themselves like rope-dancers, succeeded in passing along a ridge of slags, so narrow that there was scarcely room for their feet. After a short, but very steep ascent, they gained the highest part of this celebrated mountain.

Its earliest eruption is said to have happened in 1004, since which time upward of twenty have occurred. That of 1693 was the most dreadful, and occasioned terrible devastations, the ashes having been thrown over the island in every direction, to the distance of more than one hundred miles. In 1728, a fire broke out among the surrounding lava; and also in that to the west of the volcano, in 1754, which lasted for three days. There has not been any eruption of lava since 1766; but for some years after, flames issued from the volcano.

THE GEYSERS.

[See cut on page 29.]

“Nor stops the restless fluid, mounting still, Though oft amid th’ irriguous vale of springs; But to the mountain courted by the sand, That leads it darkling on in faithful maze, Far from the parent main, it boils again! Fresh into day; and all the glittering hill Is bright with spouting rills. The crystal treasures of the liquid world, Through the stirred sands a bubbling passage burst; And welling out, around the middle steep, Or from the bottoms of the bosomed hills, In pure effusion flow.”—THOMSON.

These celebrated fountains, or hot spouting water springs, being nearly connected with the operations of subterraneous fire, so visible in every part of Iceland, may be properly introduced after the description of Mount Hecla, given above.

They are seldom very near the volcanoes, but are dispersed over the whole country, and are even to be found on the summits of several of the ice mountains. The largest and most remarkable of these is situated in a large field, about sixteen miles to the north of Skalholt. At a great distance from it, on one side, are high mountains covered with ice, and on the other Hecla is seen rising above the clouds, while opposite to it is a ridge of rocks, at the foot of which water from time to time rushes forth. At the distance of a mile and a half, a loud roaring noise is heard, like that of a torrent precipitated from stupendous rocks, each ejection being accompanied by violent subterraneous detonations. The depth of the opening from which the water rushes, has not been ascertained; but some seconds elapse before a stone thrown in reaches the surface. The Danish traveler, Olafsen, asserts, that the water rises as high as sixty fathoms: while Van Troil estimates the highest jet at not more than sixty feet: the latter allows, however,

that the jets may be more elevated, particularly in bad weather. The greatness of the explosive power is evinced by its not only preventing stones thrown in from sinking, but even forcing them up to a very great hight, together with the water, and splitting the pebbles into a thousand pieces. The heat was found by Van Troil to be two hundred and twelve degrees of Fahrenheit, the boiling point. The edges of the pipe or basin are covered by a coarse stalactitic rind, and the water has been found to have a petrifying quality. The opening is perfectly circular, in diameter nineteen feet, and forms above, on the surface of the ground, a basin fifty-nine feet in diameter, the edge of which is nine feet above the orifice or hole.

In speaking of the Geysers, or hot spouting springs, Horrebow observes, that if you fill a bottle at one of them, the water it contains will boil three or four times, at the same time with the water in the well. The inhabitants boil their meat in it, by putting the meat in a vessel of cold water, which they place in the hot spring.

Sir G. S. Mackenzie, whose travels in Iceland we have already cited, visited the Geysers at a season favorable to his observations, the latter end of July. He found the cultivation of the surrounding territory much higher than might have been inferred from the idea generally entertained of the barren and unproductive state of Iceland. All the flat ground in that quarter of the island was swampy, but not so much so as to impede the progress of the party, who, having passed several hot springs to the eastward of Skalholt, and others rising among the low hills they had left to the right, in proceeding to the great Geyser, came to a farm-house, situated on a rising ground in the midst of the bogs. Here the people were busily employed in making hay, a scene which afforded a pleasing change from the dreary solitude they had quitted. The whole of this extensive district, which abounds in grass, would, if drained, our traveler observes, prove a very rich pasture country. Farther on they came to several cottages at the foot of the mountain, round which they turned, and came in sight of the hill having the Geysers at one of its sides. This hill, in hight not more than three hundred feet, is separated from the mountain, toward the west, by a narrow slip of flat boggy ground, connected with that which extends over the whole valley. Having crossed this bog, and a small river which ran through it, the party came to a farm-house at the east end of the hill, and arrived at a spot where the most wonderful and awful effects of subterraneous heat are exhibited.

On the east side of the hill there are several banks of clay, from some of which steam rises in different places; and in others there are cavities, in which water boils briskly. In a few of these cavities, the water being mixed with clay, is thick and varies in color; but is chiefly red and gray. Below these banks there is a gentle and uniform slope, composed of matter which, at some distant period, has been deposited by springs which no longer exist. The strata or beds thus formed, seemed to have been broken by shocks of earthquakes, particularly near the great Geyser. Within a space not exceeding a quarter of a mile, numerous orifices are seen in the old incrustations, from which boiling water and steam issue, with different degrees of force. At the northern extremity is situated the great Geyser, sufficiently distinguishable from the others by every circumstance connected with it. On approaching this spot, it appeared that a mount had been formed of irregular, rough-looking depositions, upon the ancient regular strata, the origin of which had been similar. The slope of the latter has caused the mount to spread more on the east side; and the recent depositions of the water may be traced till they coincide with them. The perpendicular hight of the mount is about seven feet, measured from the highest part of the surface of the old depositions. From these the matter composing the mount may be readily distinguished, on the west side, where a disruption has taken place. On the top of this mount is a basin, which was found to extend fifty-six feet in one direction, and forty-six in another.

At a quarter before three o’clock in the afternoon, when the party reached the spot, they found the basin full of hot water, a little of which was running over. Having satisfied their curiosity at that time, they proceeded to examine some other places, whence they saw water ascending. Above the great Geyser, at a short distance, they came to a large irregular opening, the beauties of which, the writer observes, it is hardly possible to describe. The water with which it was filled was as clear as crystal, and perfectly still, although nearly at the boiling point. Through it they saw white incrustations, forming a variety of figures and cavities, to a great depth, and carrying the eye into a vast and dark abyss, over which the crust supporting them formed a dome of an inconsiderable thickness; a circumstance which though not of itself agreeable, contributed much to the effects of this awful scene.

Having pitched their tent at the distance of about one hundred yards from the Geyser, and so arranged matters that a regular watch might be kept during the night, Sir G. S. Mackenzie took his station at eleven o’clock, and his companions lay down to sleep. About ten minutes before twelve he heard subterraneous discharges, and waked his friends. The water in the basin was greatly agitated, and flowed over, but there was not any jet. The same occurred at half past two. At five minutes past four on Saturday morning, an alarm was given by one of the company. As our traveler lay next the door of the tent, he instantly drew aside the canvas, when at the distance of little more than fifty yards, a most extraordinary and magnificent appearance presented itself. From a place they had not before noticed, they saw water thrown up, and steam issuing with a tremendous noise. There was little water; but the force with which the steam escaped, produced a white column of spray and vapor, at least sixty feet high. They enjoyed this astonishing and

beautiful sight until seven o'clock, when it gradually disappeared.

The remaining part of the morning was occupied in examining the environs of the Geysers; and at every step they received some new gratification. Following the channel which had been formed by the water escaping from the great basin during the eruptions, they found several beautiful and delicate petrifactions. The leaves of birch and willow were seen converted into white stone, and in the most perfect state of preservation, every minute fiber being entire. Grass and rushes were in the same state, and also masses of peat. Several of these rare and elegant specimens were brought safely to Great Britain. On the outside of the mount of the Geyser, the depositions, owing to the splashing of the water, are rough and have been justly compared to the heads of cauliflowers. They are of a yellowish brown color, and are arranged around the mount, somewhat like a circular flight of steps. The inside of the basin is comparatively smooth: and the matter forming it is more compact and dense than the exterior crust; when polished it is not devoid of beauty, being of a gray color, mottled with black and white spots and streaks. The white incrustation formed by the water of the beautiful cavity before described, had taken a very curious form at the water's edge, very much resembling the capital of a Gothic column.

THE SULPHUR MOUNTAIN.

This mountain of Iceland, distant about three miles from the village of Krisuvik, presents a phenomenon very different from the one which has just been described, _viz._, that of a CALDRON OF BOILING MUD. We extract the following particulars of this singular curiosity from the relation given by Sir G. S. Mackenzie in his travels in Iceland.

At the foot of the mountain is a small bank, composed chiefly of white clay and sulphur, from every part of which steam issues. Having ascended this bank, a ridge presents itself, immediately beneath which is a deep hollow, whence a profusion of vapor arises, with a confused noise of boiling and splashing, accompanied by steam escaping from narrow crevices in the rock. This hollow, as well as the whole side of the mountain opposite, being covered with sulphur and clay, it was very hazardous to walk over a soft and steaming surface of such a description. The vapor concealing the party from each other occasioned much uneasiness; and there was some hazard of the crust of sulphur breaking, or of the clay sinking beneath their feet. They were thus several times in danger of being scalded, as indeed, happened to one of the party, Mr. Bright, who accidentally plunged one of his legs into the hot clay. When the thermometer was immersed in it, to the depth of a few inches, it generally rose to within a few degrees of the boiling point. By stepping cautiously, and avoiding every little hole from which steam issued, they soon ascertained how far they might venture. Their good fortune, however, Sir George observes, ought not to tempt any person to examine this wonderful place, without being provided with two boards, with which every part of the banks may be traversed in perfect safety. At the bottom of the hollow, above described, they found the caldron of mud, which boiled with the utmost vehemence. They approached within a few yards of it, the wind favoring them in viewing every part of this singular scene. The mud was in constant agitation, and often thrown up to the hight of six or eight feet. Near this spot was an irregular space filled with water, boiling briskly. At the foot of the hill, in a hollow formed by a bank of clay and sulphur, steam rushed with great force and noise from among the loose fragments of rock.

In ascending the mountain, our travelers met with a spring of cold water, which was little to be expected in such a place. At a greater elevation, they came to a ridge, composed entirely of sulphur and clay, joining two summits of the mountain. The smooth crust of sulphur was beautifully crystallized; and beneath it was a quantity of loose granular sulphur, which appeared to be collecting and crystallizing, as it was sublimed along with the steam. On removing the sulphurous crust, steam issued, and annoyed the party so much, that they could not examine this place to any depth.

Beneath the ridge, on the farther side of this great bed of sulphur, an abundance of vapor escaped with a loud noise. Having crossed to the side of the mountain opposite, they walked to what is called the principal spring. This was a task of much apparent danger, as the side of the mountain to the extent of about half a mile, was covered with loose clay, into which the feet of our travelers sunk at every step. In many places there was a thin crust, beneath which the clay was wet, and extremely hot. Good fortune attended them; and without any serious inconvenience, they reached the object they had in view. A dense column of steam, mixed with a small portion of water, forced its way impetuously through a crevice in a rock, at the head of a narrow valley, or break in the mountain. The violence with which it rushed out was so great, that the noise, thus occasioned, might often be heard at the distance of several miles. During the night while the party lay in their tent at Krisuvik, they more than once listened to it with mingled awe and astonishment. Behind the column of vapor was a dark-colored rock, which added to the sublimity of the effect.

"It is quite beyond my power," observes Sir George Mackenzie, "to offer such a description of this extraordinary place, as would convey adequate ideas of its wonders, or of its terrors. The sensations of a person, even of firm nerves, standing on a support

which feebly sustains him, over an abyss where, literally, fire and brimstone are in dreadful and incessant action; having before his eyes tremendous proofs of what is going on beneath him; enveloped in thick vapors; his ears stunned with thundering noises—must be experienced before they can be understood."

MONT BLANC.

[See cut, page 38.]

"When mid the lifeless summits proud Of Alpine cliffs, where to the gelid sky Snows piled on snows in wint'ry torpor lie, The rays divine of vernal Phœbus play; Th' awakened heaps, in streamlets from on high, Roused into action, lively leap away, Glad warbling through the vales, in their new being gay."—THOMSON.

[Illustration: MONT BLANC AND THE GLACIERS.]

This mountain, in Switzerland, so named on account of its white aspect, belongs to the great central chain of the Alps. It is truly gigantic, and is the most elevated mountain in Europe, rising no less than fifteen thousand, eight hundred and seventy-two feet, somewhat more than three miles, above the level of the sea, and fourteen thousand, six hundred and twenty-four feet above the lake of Geneva, in its vicinity. It is encompassed by those wonderful collections of snow and ice, called glaciers, two of the principal of which, are called Mont Dolent and Triolet. The highest part of Mont Blanc, named the Dromedary, is in the shape of a compressed hemisphere. From that point it sinks gradually, and presents a kind of concave surface of snow, in the midst of which is a small pyramid of ice. It then rises into a second hemisphere, which is named the Middle Dome; and thence descends into another concave surface, terminating in a point, which among other names bestowed on it by the Savoyards, is styled "Dome de Goute," and may be regarded as the inferior dome.

The first successful attempt to reach the summit of Mont Blanc was made in August, 1786, by Doctor Paccard, a physician of Chamouny. He was led to make the attempt by a guide, named Balma, who, in searching for crystals, had discovered the only practicable route by which so arduous an undertaking could be accomplished. The ascent occupied fifteen hours, and the descent five, under circumstances of the greatest difficulty; the sight of the doctor, and that of his guide, Balma, being so affected by the snow and wind, as to render them almost blind, at the same time that the face of each was excoriated, and the lips exceedingly swelled.

On the first of August of the following year, 1787, the celebrated and indefatigable naturalist, M. de Saussure, set out on his successful expedition, accompanied by a servant and eighteen guides, who carried a tent and mattresses, together with the necessary accommodations and various instruments of experimental philosophy. The first night they passed under the tent, on the summit of the mountain of La Cote, four thousand, nine hundred and eight-six feet above the Priory, a large village in the vale of Chamouny, the journey thither being exempt from trouble or danger, as the ascent is always over turf, or on the solid rock; though above this place it is wholly over ice or snows.

Early next morning they traversed the glacier of La Cote, to gain the foot of a small chain of rocks, inclosed in the snows of Mont Blanc. The glacier is both difficult and dangerous, being intersected by wide, deep, irregular chasms, which frequently can be passed only by three bridges of snow, which are suspended over the abyss. After reaching the ridge of rocks, the track winds along a hollow, or valley, filled with snow, which extends north and south to the foot of the highest summit, and is divided at intervals by enormous crevices. These show the snow to be disposed in horizontal beds, each of which answers to a year, and notwithstanding the width of the fissures, the depth can in no part be measured. At four in the afternoon, the party reached the second of the three great platforms of snow they had to traverse, and here they encamped, at the hight of nine thousand, three hundred and twelve feet above the Priory, or twelve thousand, seven hundred and sixty-eight feet (nearly two miles and a half) above the level of the sea.

From the center of this platform, inclosed between the farthest summit of Mont Blanc on the south, its high steps, or terraces, on the east, and the Dome de Goute on the west, nothing but snow appears. It is quite pure, of a dazzling whiteness, and on the high summits presents a singular contrast with the sky, which in these elevated regions is almost black. Here no living being is to be seen; no appearance of vegetation: it is the abode of cold and silence. "When," observes M. de Saussure, "I represent to myself Dr. Paccard and James Balma first arriving, on the decline of day, in these deserts, without shelter, without assistance, and even without the certainty that men could live in the places which they proposed to reach, and still pursuing their career with unshaken intrepidity, it seems impossible to admire too much their strength of mind and their courage."

The company departed, at seven the next morning, to traverse the third and last platform, the slope of which is extremely steep, being in some places thirty-nine degrees. It terminates in precipices on all sides; and the surface of the snow was so hard, that those who went foremost were obliged to cut places for the feet with hatchets. The last slope of all presents no danger; but the air possesses so high a degree of rarity, that the strength is speedily exhausted, and on approaching the summit it was found necessary to stop at every fifteen or sixteen paces to take breath. At eleven they reached the top of the mountain, where they continued four hours and a half, during which time M. de Saussure enjoyed, with rapture and astonishment, a view the most extensive as well as the most rugged and sublime in nature, and made those observations which have rendered this expedition important to philosophy.

A light vapor, suspended in the lower regions of the air, concealed from the sight the lowest and most remote objects, such as the plains of France and Lombardy; but the whole surrounding assemblage of high summits appeared with the greatest distinctness.

M. de Saussure descended with his party, and the next morning reached Chamouny, without the smallest accident. As they had taken the precaution to wear vails of crape, their faces were not excoriated, nor their sight debilitated. The cold was not found to be so extremely piercing as it was described by Dr. Paccard. By experiments made with the hygrometer, on the summit of the mountain, the air was found to contain a sixth portion only of the humidity of that of Geneva; and to this dryness of the air, M. de Saussure imputes the burning thirst which he and his companions experienced. The balls of the electrometer diverged three lines only, and the electricity was positive. At times the air seems filled with electricity. A recent traveler (1854) says, that, in the night, his guide having come out from the cabin of the Grand Mulets, saw the ridges of the mountain apparently all on fire. He immediately communicated what he had observed to his companions, who all rushed to assure themselves of the fact, and then they saw that through the electricity generated by the tempest, all the rocks of the Grand Mulets were illuminated. They found the same phenomenon on their own persons. When they raised their arms, their fingers became phosphorescent. M. de Saussure found it required half an hour to make water boil, while at Geneva fifteen or sixteen minutes sufficed, and twelve or thirteen at the seaside. None of his party discovered the smallest difference in the taste or smell of bread, wine, meat, fruits or liquors, as some travelers have pretended is the case at great hights; but sounds were of course much weakened, from the want of objects of reflection. Of all the organs, that of respiration was most affected, the pulse of one of the guides beating ninety-eight times in a minute, that of the servant one hundred and twelve, and that of M. de Saussure one hundred and one; while at Chamouny, the pulsations respectively were forty-nine, sixty, and seventy-two. A few days afterward, Mr. Beaufoy, an English gentleman, succeeded in a similar attempt, although it was attended with greater difficulty, arising from enlargements in the chasms in the ice.

A late traveler, wandering amid the same sublime scenery that has been described, says:

“Mont Blanc is clearly visible from Geneva, perhaps once in the week, or about sixty times in the year. When he is visible, a walk to the junction of the Arve and the Rhone, either by the way of the plains on the Genevan side, or by the hights on the side toward the south of France, affords a wonderful combination of sublimity and beauty on the earth and in the heavens. Those snowy mountain ranges, so white, so pure, so dazzling in the clear azure depths, do really look as if they belonged to another world; as if, like the faces of supernatural intelligences, they were looking sadly and steadfastly on our world, to speak to us of theirs. Some of these mountain peaks of snow you can see only through the perspective of other mountains, nearer to you, and covered with verdure, which makes the snowy pyramids appear so distant, so sharply defined, so high up, so glorious; it is indeed like the voice of great truths stirring the soul. As your eye follows the range, they lie in such glittering masses against the horizon, in such grand repose; they shoot into the sky in bright weather in such infinite clearness, so pure, so flashing; that they seem never to lose the charm of a sudden and startling revelation to the mind. Are they not sublime images of the great truths of God’s own word, that sometimes indeed are vailed with clouds, but in fair weather do carry us, as in a chariot of fire and with horses of fire, into eternity, into the presence of God? The atmosphere of our hearts is so misty and stormy, that we do not see them more than sixty times a year in their glory: if every Sabbath-day we get a view of them without clouds, we do well; but _when_ we see them as they are, then we feel their power, then we are rapt by them from earth, away, away, away, into the depths of heaven!

“In some circumstances, when we are climbing the mountains, even the mists that hang around them do add to the glory of the view; as in the rising sun, when they are so penetrated with brightness, that they softly rise over the crags as a robe of misty light, or seem like the motion of sweet Nature breathing into the atmosphere from her morning altars the incense of praise. And in the setting sun how often do they hang around the precipices, glowing with the golden and crimson hues of the west, and preventing us from clearly defining the forms of the mountains, only to make them more lovely to our view. So it is sometimes with the very clouds around God’s word, and the lights and shades upon it. There is an inscrutability of truth which sometimes increases its power, while we wait with solemn reverence for the hour when it shall be fully revealed to us; and our faith, like the setting sun, may clothe

celestial mysteries with a soft and rosy-colored light, which makes them more suitable to our present existence, than if we saw them in the clear and cloudless atmosphere of a spiritual noon.

“You have a fine point for viewing Mont Blanc, without going out of the city, from the ramparts on the west side of Rousseau’s island. Here a brazen indicator is erected, with the names of the different mountain summits and ridges, so that by taking sight across the index, you can distinguish them at once. You will not mistake Mont Blanc, if you see him; but until you get accustomed to the panorama, you may easily mistake one of his court for the king, when the monarch himself is not visible.

“A still better point of view you will have at Coppet, ascending toward the Jura. In proportion as you rise from the borders of the lake, every part of the landscape becomes more beautiful, though what you wish to gain is the most commanding view of the mountains, every other object being secondary. In a bright day, nothing can be more clearly and distinctly defined than Mont Blanc, with his attendant mighty ranges, cut in dazzling snowy brightness against the clear blue sky. The sight of those glorious glittering fields and mountains of ice and snow, produces immediately a longing to be there among them. They make an impression upon the soul, of something supernatural, almost divine. Although the whole scene lying before you is so beautiful, (the lake, the verdant banks, the trees, and the lower ranges of verdure-covered mountains, constituting in themselves alone one of the loveliest pictures in the world,) yet the snowy ranges of Mont Blanc are the grand feature. Those glittering distant peaks are the only thing in the scene that takes a powerful hold upon the soul; but they do quite possess it, and tyrannize over it, with an ecstatic thralldom. One is never wearied with gazing and wondering at the glory. I will lift up mine eyes unto the hills, from whence cometh my help!

“Another admirable point, much farther from the lake and the city than the preceding, and at a greater elevation, is what is called the promenade of the point Sacconex. A fine engraving of this view is printed on letter-paper for correspondence; but there is not sufficient distinctness given to the outlines of Mont Blanc and the other summits of the glittering snowy range, that seems to float in the heavens like the far-off alabaster walls of Paradise. No language, nor any engraving, can convey the ravishing magnificence and splendor, the exciting sublimity and beauty of the scene. But there are days in which the air around the mountains seems itself of such a hazy whiteness, that the snow melts into the atmosphere as it were, and dies away in the heavens like the indistinct outline of a bright but partially remembered dream. There are other days in which the fleecy clouds, like vails of light over the faces of angels, do so rest upon and mingle with the snowy summits, that you can hardly tell where one begins and the other ends. Sometimes you look upon the clouds thinking they are mountains, and then again Mont Blanc himself will be revealed in such far-off, unmoving, glittering grandeur, in such wonderful distinctness, that there is no mistaking the changeful imitations of his glory for the reality. Sometimes the clouds and the mountains together are mingled in such a multitudinous and interminable array of radiances, that it seems like the white-robed armies of heaven with their floating banners, marching and countermarching in front of the domes and jeweled battlements of the celestial city. When the fog scenery (of which I shall give you a description) takes place upon the earth, and at the same time there are such revelations of the snowy summits in the heavens, and such goings on of glory among them, and you get upon the mountain to see them, it is impossible to describe the effect, as of a vast enchantment, upon the mind.

“The view of Geneva, the lake, and the Jura mountains from Coligny is much admired; and at sunset, perhaps the world can not offer a more lovely scene. It was here that Byron took up his abode; a choice which I have wondered at, for you can not see Mont Blanc from this point, and therefore the situation is inferior to many others. Ascending the hill farther to the east, when you come to Col. Tronchin’s beautiful residence, you have perhaps the finest of all the views of Mont Blanc, in or around Geneva. Go upon the top of Col. Tronchin’s tower about half an hour before sunset, and the scene is not unworthy of comparison even with the glory of the sunrise as witnessed from the summit of the Righi. It is surprising to see how long Mont Blanc retains the light of day, and how long the snow burns in the setting sun, after his orb has sunk from your own view entirely behind the green range of the Jura. Then after a succession of tints from the crimson to the cold gray, it being manifest that the sun has left the mountain to a companionship with the stars alone, you also are ready to depart, the glory of the scene being over, when suddenly and unaccountably the snowy summits redden again, as if the sun were returning upon them, the countenance of Mont Blanc is filled with rosy light, and the cold gray gives place for a few moments to a deep warm radiant pink, (as if you saw a sudden smile playing over the features of a sleeping angel,) which at length again dies in the twilight. This phenomenon is extremely beautiful, but I know not how to account for it; nor was any one of our party wiser than I; nevertheless, our ignorance of causes need never diminish, but often increases the pleasure of beautiful sights.”

“I have said I would give you a description of the ‘fog-scenery.’ In the autumn, when the fogs prevail, it is often a thick drizzling mist in Geneva, and nothing visible, while on the mountain tops the air is pure, and the sun shining. On such a day as this, when the children of the mist tell you that on the mountains it is fair weather, you must start early for the range nearest Geneva, on the way to

Chamouny, the range of the Grand Saléve, the base of which is about four miles distant, prepared to spend the day upon the mountains, and you will witness one of the most singular and beautiful scenes to be enjoyed in Switzerland.

“The day I set out was so misty, that I took an umbrella, for the fog gathered and fell like rain, and I more than doubted whether I should see the sun at all. In the midst of this mist I climbed the rocky zigzag half hewn out of the face of the mountain, and half natural, and passing the village that is perched among the high rocks, which might be a refuge for the conies, began toiling up the last ascent of the mountain, seeing nothing, feeling nothing, but the thick mist, the vail of which had closed below and behind me over village, path and precipice, and still continued heavy and dark above me, so that I thought I never should get out of it. Suddenly my head rose above the level of the fog into the clear air, and the heavens were shining, and Mont Blanc, with the whole illimitable range of snowy mountain tops around him, was throwing back the sun! An ocean of mist, as smooth as a chalcedony, as soft and white as the down of the eider-duck’s breast, lay over the whole lower world; and as I rose above it, and ascended the mountain to its overhanging verge, it seemed an infinite abyss of vapor, where only the mountain tops were visible, on the Jura range like verdant wooded islands, on the Mont Blanc range as glittering surges and pyramids of ice and snow. No language can describe the extraordinary sublimity and beauty of the view. A level sea of white mist in every direction, as far as the eye could extend, with a continent of mighty icebergs on the one side floating in it, and on the other a forest promontory, with a slight undulating swell in the bosom of the sea, like the long, smooth undulations of the ocean in a calm.

“Standing on the overhanging crags, I could hear the chime of bells, the hum of busy labor, and the lowing of cattle, buried in the mist, and faintly coming up to you from the fields and villages. Now and then a bird darted up out of the mist into the clear sun and air, and sailed in playful circles, and then dived and disappeared again below the surface. By and by the wind began to agitate the cloudy sea, and more and more of the mountains became visible. Sometimes you have a bright sunset athwart this sea of cloud, which then rolls in waves burnished and tipped with fire. When you go down into the mist again, and leave behind you the beautiful sky, a clear, bracing atmosphere, the bright sun and the snow-shining mountains, it is like passing from heaven to earth, from the brightness and serenity of the one, to the darkness and cares of the other. The whole scene is a leaf in nature’s book, which but few turn over; but how rich it is in beauty and glory, and in food for meditation, none can tell but those who have witnessed it. This is a scene in Cloud-land, which hath its mysteries of beauty, that defy the skill of the painter and engraver.

“The poet Wordsworth has given two very vivid descriptions of these mist phenomena, under different aspects from that in which I witnessed them. The first is contained in his descriptive sketches of a pedestrian tour among the Alps.

“‘’Tis morn: with gold the verdant mountain glows, More high, the snowy peaks with hues of rose. Far stretched beneath the many-tinted hills A mighty waste of mist the valley fills, A solemn sea! whose vales and mountains round Stand motionless, to awful silence bound. A gulf of gloomy blue, that opens wide And bottomless, divides the midway tide. Like leaning masts of stranded ships appear The pines, that near the coast their summits rear. Of cabins, woods and lawns a pleasant shore Bounds calm and clear the chaos still and hoar. Loud through that midway gulf ascending, sound, Unnumbered streams with hollow roar profound. Mount through the nearer mist the chant of birds, And talking voices, and the low of herds, The bark of dogs, the drowsy tinkling bell, And wild-wood mountain lutes of saddest swell.’

“But this extract is not to be compared for power to the following from the same poem, describing an Alpine sunset after a day of mist and storm upon the mountains.

“‘’Tis storm, and hid in mist from hour to hour, All day the floods a deepening murmur pour. The sky is vailed, and every cheerful sight, Dark is the region as with coming night, But what a sudden burst of overpowering light Triumphant on the bosom of the storm Glances the fire-clad eagle’s wheeling form. Eastward, in long perspective glittering, shine The wood-crowned cliffs, that o’er the lake recline. Wide o’er the Alps a hundred streams unfold, At once to pillars turned, that flame with gold. Behind his sail the peasant tries to shun The west, that burns like one dilated sun, Where in a mighty crucible expire The mountains, glowing hot, like coals of fire!’

“There was a time during the middle ages, when Chamouny was inhabited by monks. The reigning lord of the country made a present of the whole valley to a convent of Benedictine friars, in the eleventh century. Two English travelers, Messrs. Pococke and Windham, drew attention to its wonderful scenery in 1741, and now it is a grand highway of summer travel, visited annually by three or four thousand people. A visit to Mont Blanc has become a pilgrimage of fashion. Fashion does some good things in her day; and it is a great thing to have the steps of men directed into this grand temple of nature, who would otherwise be dawdling the summer perhaps at immoral watering-places. A man can hardly pass through the vale of Chamouny, before the awful face of Mont Blanc,

and not feel that he is an immortal being. The great mountain looks with an eye, and speaks with a voice, that does something to wake the soul out of its slumbers.

“The sublime hymn by Coleridge, in the vale before sunrise, is the concentrated expression of all the inspiring and heaven-directing influences of the scenery. The poem is as remarkably distinguished above the whole range of poetry in our language, for its sublimity, as the mountain itself among all the great ranges of the Alps. I am determined to quote it in full, for that and the tour of Mont Blanc ought to go together; and I will present along with it the German original of the poem in twenty lines, nearly as translated by Coleridge’s admiring and affectionate relative. I am not aware that Coleridge himself ever visited the vale of Chamouny; and if not, then that wonderful hymn to Mont Blanc was the work of imagination solely, building on the basis of the original lines in German. This was a grand and noble foundation, it is true; but the hymn by Coleridge was a perfect transfiguration of the piece, an inspiration of it with a higher soul, and an investiture of it with garments that shine like the sun. It was the greatest work of the poet’s great and powerful imagination, combined with the deep worshiping sense of spiritual things in his soul.

“On visiting the scene, one is apt to feel as if he could not have written it in the vale itself: the details of the picture would have been somewhat different; and, confined by the reality, one may doubt if even Coleridge’s genius could have gained that lofty ideal point of observation and conception, from which he drew the vast and glorious imagery that rose before him. Not because the poem is more glorious than the reality, for that is impossible; but because, in painting _from_ the reality, the force and sublimity of his general conceptions would have been weakened by the attempt at faithfulness in the detail, and nothing like the impression of the aerial grandeur of the scene, its despotic unity in the imagination, notwithstanding its variety, would have been conveyed to the mind.

“Yet there are parts of it which at sunrise or sunset either, the poet might have written from the very windows of his bedroom, if he had been there in the dawn and evenings of days of such extraordinary brilliancy and glory, as marked and filled the atmosphere, during our sojourn in that blessed region. A glorious region it is, much nearer heaven than our common world, and carrying a sensitive, rightly constituted mind far up in spirit toward the gates of heaven, toward God, whose glory is the light of heaven, and of whose power and majesty the mountains, ice-fields and glaciers, whether beneath the sun, moon, or stars, are a dim, though grand and glittering, symbol. ‘Fire and hail, snow and vapor, stormy wind, fulfilling His word, mountains and all hills, fruitful trees and all cedars, praise the Lord. He looketh on the earth and it trembleth; He toucheth the hills, and they smoke.’

“The following is the original German hymn, in what the translator denominates a very bald English translation, to be compared as a curiosity with its glorification in Coleridge. It occupies but five stanzas of four lines, and is entitled, ‘Chamouny at Sunrise. To Klopstock.’ I have here put it into the metrical form of the original.

“Out of the deep shade of the silent fir-grove, Trembling I survey thee, mountain-head of eternity, Dazzling (blinding) summit, from whose vast hight My dimly perceiving spirit floats into the Everlasting.

“Who sank the pillar deep in the lap of earth Which, for past centuries, fast props thy mass up? Who uptowered, high in the vault of ether, Mighty and bold, thy beaming countenance?

“Who poured you from on high, out of eternal Winter’s realm, O jagged streams, downward with thunder-noise? And who bade aloud, with the Almighty Voice, ‘Here shall rest the stiffening billows?’

“Who marks out there the path for the Morning Star? Who wreathes with blossoms the skirt of eternal Frost? To whom, wild Arveiron, in terrible harmonies, Rolls up the sound of thy tumult of billows?

“Jehovah! Jehovah! crashes in the bursting ice! Avalanche-thunders roll it in the cleft downward: Jehovah! it rustles in the bright tree-tops; It whispers murmuring in the purling silver-brooks.

“This is very grand. Who but a mighty poet, one seeing with ‘the vision and the faculty divine’—what, but a transfusing, all-conquering imagination—would have dared the attempt to compose another poem on the same subject, or to carry this to a greater hight of sublimity, by melting it down anew, so to speak, and pouring it out into a vaster, more glorious mold? The more one thinks of it, the more he will see, in the poem so produced, a proof most remarkable, of the spontaneous, deep-seated, easily exerted, and almost exhaustless power and originality of Coleridge’s genius. Now let us peruse, ‘with mute thanks and secret ecstacy,’ his own solemn and stupendous lines.

HYMN BEFORE SUNRISE, IN THE VALE OF CHAMOUNY.

[Besides the rivers Arve and Arveiron, which have their sources in the foot of Mont Blanc, five conspicuous torrents rush down its sides; and, within a few paces of the glaciers, the Gentiana Major grows in immense numbers, with its ‘flowers of loveliest blue.’]

“Hast thou a charm to stay the Morning Star In his steep course? so long he seems to pause On thy bald, awful head, O Sovran Blanc? The Arve and Arveiron at thy base Rave ceaselessly; but thou, most awful form! Risest from forth thy silent sea of pines, How silently! Around thee and above, Deep is the air, and dark, substantial, black; An ebon mass: methinks thou piercest it As with a wedge! But when I look again, It is thine own calm home, thy crystal shrine, Thy habitation from Eternity!

“O dread and silent Mount! I gazed upon thee, Till thou, still present to the bodily sense, Didst vanish from my thought: entranced in prayer I worshiped the Invisible alone.

“Yet, like some sweet, beguiling melody, So sweet, we know not we are listening to it, Thou, the meanwhile, wast blending with my thought, Yea, with my life, and life’s own secret joy, Till the dilating Soul, enrapt, transfused, Into the mighty vision passing,—there, As in her natural form, swelled vast to heaven!

“Awake my Soul! not only passive praise Thou owest! not alone these swelling tears, Mute thanks and secret ecstacy! Awake, Voice of sweet song! Awake, my heart, awake! Green vales and icy cliffs, all join my hymn.

“Thou first and chief, sole sovran of the vale Oh, struggling with the darkness all night long, And all night visited by troops of stars, Or when they climb the sky, or when they sink! Companion of the morning star at dawn, Thyself earth’s rosy star, and of the dawn Coherald: wake, oh wake, and utter praise! Who sank thy sunless pillars deep in earth? Who filled thy countenance with rosy light? Who made thee parent of perpetual streams?

“And you, ye five wild torrents, fiercely glad! Who called you forth from night and utter death, From dark and icy caverns called you forth, Down those precipitous, black, jagged rocks, Forever shattered, and the same forever? Who gave you your invulnerable life, Your strength, your speed, your fury and your joy, Unceasing thunder and eternal foam? And who commanded (and the silence came,) Here let the billows stiffen and have rest?

“Ye ice-falls! ye that from the mountain’s brow, Adown enormous ravines slope amain— Torrents, methinks, that heard a mighty voice, And stopped at once, amidst their maddest plunge! Motionless torrents! silent cataracts! Who made you glorious as the gates of heaven Beneath the keen full moon? Who bade the sun Clothe you with rainbows? Who, with living flowers Of loveliest blue, spread garlands at your feet? GOD! let the torrents, like a shout of nations, Answer! and let the ice-plains echo, GOD! GOD! sing, ye meadow-streams, with gladsome voice! Ye pine-groves, with your soft and soul-like sounds! And they, too, have a voice, yon piles of snow, And in their perilous fall shall thunder, GOD!

“Ye living flowers, that skirt the eternal frost! Ye wild goats sporting round the eagle’s nest! Ye eagles, playmates of the mountain-storm! Ye lightnings, the dread arrows of the clouds! Ye signs and wonders of the elements! Utter forth GOD! and fill the hills with praise!

“Thou, too, hoar Mount, with thy sky-pointing peaks, Oft from whose feet, the avalanche, unheard, Shoots downward, glittering through the pure serene Into the depths of clouds, that vail thy breast; Thou too again, stupendous mountain! thou, That as I raise my head, awhile bowed low In adoration, upward from thy base Slow traveling with dim eyes suffused with tears, Solemnly seemest, like a vapory cloud, To rise before me,—Rise, oh ever rise! Rise, like a cloud of incense, from the earth! Thou kingly spirit throned among the hills, Thou dread embassador from Earth to Heaven, Great Hierarch! tell thou the silent sky, And tell the stars, and tell yon rising sun, Earth, with her thousand voices, praises God!

“Thanks to thee, thou noble poet, for giving this glorious voice to Alpine nature, for so befitting and not unworthy an interpretation of Nature’s own voice, in words of our own mother-tongue. Thanks to God for his grace vouchsafed to thee, so that now thou praisest Him amidst the infinite host of flaming seraphs, before the mount supreme of glory, where all the empyrean rings with angelic hallelujahs! The creation of such a mind as Coleridge’s, is only outdone by its redemption through the blood of the Lamb. Oh, who can tell the rapture of a soul, that could give a voice for nations to such a mighty burst of praise to God in this world, when its powers, uplifted in eternity, and dilated with absorbing, unmingled, unutterable love, shall pour themselves forth in the anthem of redemption, Worthy is the Lamb that was slain!”

THE GLACIERS, OR ICE MASSES.

The three great glaciers, or ice-mountains, which descend from the flanks of Mont Blanc, add their ice to that of the Miage, and present a majestic spectacle, amid the astonishing succession of icy summits, of deep valleys, and of wide chasms, which have become channels for the innumerable torrents and cataracts with which these mountains abound. The view which the glacier of Talafre affords from its center, looking toward the north, is as extraordinary as beautiful. It rises gradually to the base of a semicircular girdle, formed of peaks of granite of a great hight, and terminating in sharp summits, extremely varied in their forms; while the intervals between these peaks are filled up by ice, which falls into this mass, and this mass of ice is crowned by masses of snow, rising in festoons between the black and vertical tables of granite, the steepness of which does not allow them to remain. A ridge of shattered wrecks divides this glacier lengthwise, and forms its most elevated part, being eight thousand, five hundred and thirty-eight feet, or upward of a mile and a half above the level of the sea. This prospect has nothing in common with what is seen in other parts of the world. The immense masses of ice, surrounded and surmounted by pyramidal rocks, still more enormous in magnitude; the contrast between the whiteness of the snow and the obscure colors of the stones, moistened by the water which trickles down their sides; the purity of the air; the dazzling light of the sun, which gives to these objects extraordinary brilliancy; the majestic and awful silence which reigns in these vast solitudes, a silence which is only interrupted at intervals by the noise of some great mass of granite, or of ice, tumbling from the top of the mountain; and the nakedness of these elevated rocks themselves, on which neither animals, shrubs, nor verdure are to be seen, combined with the recollection of the fertile country and rich vegetation which the adjacent valleys at so small a distance present; all tend to produce a mixed impression of admiration and terror, which tempts the spectator to believe, that he has been suddenly transported into a world forgotten by the great Author of nature. One of these glaciers, that of Triolet, is covered with the wrecks of another ice-mountain, which fell some years ago, and buried many huts, flocks, and shepherds beneath its ruins.

THE MER DE GLACE.

These glaciers have their foundation in the wonderful =Mer de Glace=, or =Sea of Ice=; shooting up from it their sharp peaks into the frozen air. “To get the best view of it as a whole,” says a modern Alpine tourist, “you cross the meadows in the vale of Chamouny, step over the furious Arve, and climb the mountain precipices to the hight of two thousand feet, by a rough, craggy path, sometimes winding amidst a wood of firs, and sometimes wandering over green grasses. At Montanvert you find yourself on the extremity of a plateau, so situated, that on one side you may look down into the dread frozen sea, and on the other, by a few steps, into the lovely green vale of Chamouny! What astonishing variety and contrast in the spectacle! Far beneath, a smiling and verdant valley, watered by the Arve, with hamlets, fields and gardens, the abode of life, sweet children and flowers; far above, savage and inaccessible crags of ice and granite, and a cataract of stiffened billows, stretching away beyond sight—the throne of death and winter.

“From the bosom of the tumbling sea of ice, huge granite needles shoot into the sky, objects of singular sublimity, one of them rising to the great hight of thirteen thousand feet, seven thousand above the point where you are standing. This is more than double the hight of Mount Washington in our country, and this amazing pinnacle of rock looks like the spire of an interminable colossal cathedral, with other pinnacles around it. No snow can cling to the summits of these jagged spires; the lightning does not splinter them; the tempests rave round them; and at their base, those eternal drifting ranges of snow are formed, that sweep down into the frozen sea, and feed the perpetual, immeasurable masses of the glacier. Meanwhile, the laughing verdure, sprinkled with flowers, plays upon the edges of the enormous masses of ice, so near, that you may almost touch the ice with one hand, and with the other pluck the violet. So, oftentimes, the ice and the verdure are mingled in our earthly pilgrimage; so, sometimes, in one and the same family, you may see the exquisite refinements and the coarse repugnancies of human nature. So, in the same house of God, on the same bench, may sit an angel and a murderer; a villain, like a glacier, and a man with a heart like a sweet running brook in the sunshine.

“The impetuous arrested cataract seems as if it were plowing the rocky gorge with its turbulent surges. Indeed, the ridges of rocky fragments along the edges of the glacier, called _moraines_, do look precisely as if a colossal iron plow had torn them from the mountain, and laid them along in one continuous furrow on the frozen verge. It is a scene of stupendous sublimity. These mighty granite peaks, hewn and pinnacled into Gothic towers, and these rugged mountain-walls and buttresses—what a cathedral! with this cloudless sky, by starlight, for its fretted roof; the chanting wail of the tempest, and the rushing of the avalanche for its organ. How grand the thundering sound of the vast masses of ice tumbling from the roof of the Arve-cavern at the foot of the glacier! Does it not seem, as it sullenly and heavily echoes, and rolls up from so immense a distance below, even more sublime than the thunder of the avalanche above us? We could tell better if we could have a genuine upper avalanche to compare with it. But what a stupendous scene! ‘I begin now,’ said my companion, ‘to understand the origin of the Gothic architecture.’ This was a very natural

feeling; but, after all, it could not have been such a scene, that gave birth to the great idea of that ‘frozen poetry’ of the middle ages. Far more likely it was the sounding aisles of the dim woods, with their checkered green light, and festooned, pointing arches.

“The colossal furrows of rocks and gravel along the edges of the ice at the shores of the sea, are produced by the action of the frost and the avalanches, with the march of the glacier against the sides of the mountains. Nothing can be more singular than these ridges of mountain =debris=, apparently plowed up and worked off by the moving of the whole bed of ice down the valley. Near the shore, the sea is turbid with these rocks and gravel; but as you go out into the channel, the ice becomes clearer and more glittering, the crevices and fissures deeper and more dangerous, and all the phenomena more astonishing. Deep, blue, pellucid founts of ice-cold water lie in the opening gulfs; and sometimes, putting your ear to the yawning fissures, you may hear the rippling of the rills below, that from the bosom of the glacier are hurrying down to constitute the Arve, bursting furiously forth from the great ice-cavern in the valley.

“This Mer de Glace is an easy and excellent residence for the scientific study of the glaciers, a subject of very great interest, formerly filled with mysteries, which the bold and persevering investigations and theories of some modern naturalists have quite cleared up. The strange movements of the glaciers, their apparent willful rejection of extraneous bodies and substances to the surface and the margin, their increase and decrease, long remained invested with something of the supernatural: they seemed to have a soul and a life of their own. They look motionless and silent, yet they are always moving and sounding on, and they have great voices that give prophetic warning of the weather to the shepherds of the Alps. Scientific men have set up huts upon the sea, and landmarks on the mountains opposite, to test the progress of the icy masses, and in this way it was found that a cabin constructed by Professor Hugi on the glacier of the Aar, had traveled, between the years 1827 and 1840, a distance of forty-six hundred feet. It is supposed that the Mer de Glace moves down between four and five hundred feet annually.

“It is impossible to form a grander image of the rigidity and barrenness, the coldness and death of winter, than when you stand among the billows of one of these frozen seas; and yet it is here that Nature locks up in her careful bosom the treasures of the Alpine valleys, the sources of rich summer verdure and vegetable life. They are hoarded up in winter, to be poured forth beneath the sun, and with the sun in summer. Some of the largest rivers in Europe take their rise from the glaciers, and give to the Swiss valleys their most abundant supply of water, in the season when ordinary streams are dried up. This is a most interesting provision in the economy of nature, for if the glaciers did not exist, those verdant valleys into which the summer sun pours with such fervor, would be parched with drought. So the mountains are parents of perpetual streams, and the glaciers are reservoirs of plenty.

“The derivation of the German name for glacier, =gletscher=, is suggested as coming not from their icy material, but their perpetual motion, from =glitschen=, to glide; more probably, however, from the idea of gliding upon their surface. These glaciers come down from the air, down out of heaven, a perpetual frozen motion, ever changing and gliding, from the first fall of snow in the atmosphere, through the state of consolidated grinding blocks of ice, and then into musical streams that water the valleys. First it is a powdery, feathery snow, then granulated like hail, and denominated _firn_, forming vast beds and sheets around the highest mountain summits, then frozen into masses, by which time it has traveled down to within seven thousand feet above the level of the sea, where commences the great ice-ocean that fills the uninhabitable Alpine valleys, unceasingly freezing, melting and moving down. It has been estimated by Saussure and others, that these seas of ice, at their greatest thickness, are six or eight hundred feet deep. They are traversed by deep fissures, and as they approach the great precipices, over which they plunge like a cataract into the vales, they are split in all directions, and heaved up into waves, reefs, peaks, pinnacles and minarets. Underneath they are traversed by as many galleries and caverns, through which run the rills and torrents constantly gathering from the melting masses above. These innumerable streams, gathering in one as they approach the termination of the glacier, rush out from beneath it, under a great vault of ice, and thus are born into the breathing world, full-grown roaring rivers, from night, frost and chaos.

“A peasant has been known to have fallen into an ice-gulf in one of these seas, near one of the flowing sub-glacial torrents, and following the course of the stream to the foot of the glacier, he came out alive! The German naturalist, Hugi, set out to explore the recesses of one of the glaciers through the bed of a former torrent, and wandered on in its ice-caverns the distance of a mile. ‘The ice was everywhere eaten away into dome-shaped hollows, varying from two to twelve feet in hight, so that the whole mass of the glacier rested at intervals on pillars, or feet of ice, irregular in size and shape, which had been left standing. As soon as any of these props gave way, a portion of the glacier would of course fall in and move on. A dim twilight, scantily transmitted through the mass of ice above, prevailed in these caverns of ice, not sufficient to allow one to read, except close to the fissures, which directly admitted the daylight. The intense blue of the mass of the ice contrasted remarkably with the pure white of the icy stalactites, or pendents descending from the roof. The water streamed down upon him from all sides, so that, after wandering about for two hours, at times bending and creeping, to get along under the low vault, he returned to the open air, quite drenched and half-frozen.’

“This sea of ice, which embosoms in its farthest recesses a little living flower-garden, whither the humble-bees from Chamouny resort for honey, is also bordered by steep lonely beds of the fragrant rhododendron, or rose of the Alps. This hardy and beautiful flower grows from a bush larger than our sweet-fern, with foliage like the leaves of the ivory-plum. It continues blooming late in the season, and sometimes covers vast declivities on the mountains at a great hight, where one would hardly suppose it possible for a handful of earth to cling to the rocky surface. There, amid the snows and ice of a thousand winters, it pours forth its perfume on the air, though there be none to inhale the fragrance, or praise the sweetness, save only ‘the little busy bees,’ that seem dizzy with delight, as they throw themselves into the bosom of these beds of roses.

“Higher still on the opposite side of this great ice-sea, there are mountain-slopes of grass at the base of stupendous rocky pinnacles, whither the shepherds of the Alps drive their herds from Chamouny, for three months’ pasturage. They have no way of getting them there but across the dangerous glacier; and it is said that the passage is a sort of annual celebration, when men, women and children go up to Montanvert, to witness and assist the difficult transportation. When the herds have crossed, one peasant stays with them for the whole three months of their summer excursion, living upon bread and cheese, with one cow among the herd to supply him with milk. When he is not sleeping, he knits stockings, and ruminates as contentedly as the browsing cattle, his only care being to increase his store.”

VIEW FROM THE BUET.

Before we take our leave of Mont Blanc and of the Alps, the peculiarly brilliant view from the summit of the Buet ought to be noticed. Never, says M. Bourrit, did prospect appear so vast. Toward the west, the Rhone is seen, winding for the space of thirty-six leagues through the rich plains of the Valais; the parts of the river which the mountains cover with their shade seeming like threads of silver, and those which the sun illumines like threads of gold. Beyond the river and its rich plains, the view extends to the highest mountains of Switzerland, St. Gothard, and the Grisons, all covered with ice; while on the east, the hights sink suddenly, from some of the loftiest elevations on the globe, to level plains washed by the sea. Geneva seems like a spot at one end of the lake, and the lake itself like a sinuous band, dividing the fields which it waters. Beyond it are discovered the vast plains of Franche Comte and Burgundy, the mountains of which diminish by almost imperceptible gradations. Here the eye has neither power nor extent of sight to embrace the whole of the objects presented to its view. Amid the fearful aspect of the precipices which descend on every side, what a contrast between the country decorated with all that is smiling and gay, and the sublime spectacle of the Alps, their gloomy and aspiring summits, and, above all, the prodigious hight of Mont Blanc, that enormous colossus of snow and ice, which parts the clouds, and pierces to the very heavens! Below this mountain, which bids defiance to time, and whose eternal ice disregards the dissolving power of the sun, a band of pyramidical rocks appear, the intervals between them being so many valleys of ice, the immensity of which appalls the imagination. Their deep chasms may be distinguished, and the noise of the frequent avalanches (falls of immense masses of snow) presents to the mind the gloomy ideas of horror, devastation and ruin. Farther on, other summits of ice prolong this majestic picture. Among these are the high mountains of the St. Bernard, and those which border on the Boromean islands.

Perhaps there is not in the old world a theater more instructive, or more adapted for reflection, than the summit of this mountain. Where, beside, can be seen such variety and contrast of forms; such results of the efforts of time; such effects of all the climates, and of all the seasons? At one glance may be embraced frosts equally intense with those of Lapland, and the rich and delightful frontiers of Italy; eternal ice, and waving harvests; all the chilling horrors of winter, and the luxuriant vegetation of summer; eighty leagues of fertile plains, covered with towns, with vineyards, with fields and herds, and adjoining to these, a depth of twenty thousand feet of everlasting ice.

MONTSERRAT.

“Here, ’midst the changeful scenery, ever new, Fancy a thousand wond’rous forms descries, More wildly great than ever pencil drew; Rocks, torrents, gulfs, and shapes of giant size, And glittering cliffs on cliffs, and fiery ramparts rise.”—BEATTIE.

This Spanish mountain, which has been so long celebrated on account of the singularity of its shape, but chiefly for its convent and its numerous hermitages, is nine leagues north-west of Barcelona, in the province of Catalonia. It is in hight only three thousand, three hundred feet above the level of the sea, but it commands an enchanting prospect of the fine plain of Barcelona, extending to the sea, as well as of the islands of Majorca and Minorca, distant one hundred and fifty miles.

Toward Barcelona this mountain presents a bold and rugged front; but on the west, toward Vacarisas, it is almost perpendicular, notwithstanding which, a carriage-road winds round to the convent, which is placed in a sheltered recess among the rocks, at about

half the hight of the mountain. The Llobregat roars at the bottom; and the rock presents perpendicular walls from the edge of the water: but above the convent, the mountain divides into two crowns or cones, which form the most prominent features; while smaller pinnacles, blanched and bare, and split into pillars, pipes, and other singular shapes, give a most picturesque effect. Here are seen fourteen or fifteen hermitages, which are scattered over different points of the mountain, some of them on the very pinnacles of the cones, to which they seem to grow, while others are placed in cavities hewn out of the loftiest pyramids. The highest accessible part of the mountain is above the hermitage of St. Maddelena, the descent from which is between two cones, by a flight of steps, called Jacob's ladder, leading into a valley which runs along the summit of the mountain. The cones are here in the most grotesque shapes, the southern one being named the Organ, from its resemblance to a number of pipes.

At the extremity of this valley, which is a perfect shrubbery, and on an eminence, stands the hermitage of St. Jerome, the highest and most remote of all; and near it is the loftiest station of the whole mountain, on which is a little chapel dedicated to the Virgin. From this elevated pinnacle the prospect is vast and splendid.

Although the elements have wreaked all their fury on these shattered peaks, yet Nature has not been sparing in her gifts; the spaces between the rocks being filled up with close woods, while numerous evergreens, and other plants, serve to adorn the various chasms, rendering them valuable depositories of the vegetable kingdom. Few, indeed, are the evergreens of Europe which may not be found here; and when the mountain was visited by Mr. Swinburne, the apothecary of the convent had a list of four hundred and thirty-seven species of plants, and forty of trees, which shoot up spontaneously, and grace this hoary and venerable pile. There being two springs only on the mountain, there is a scarcity of water, which is chiefly collected in cisterns; an inconvenience, however, which is in a great measure counterbalanced by the absence of wolves, bears, and other wild beasts.

Captain Carlton, an Englishman, who visited Montserrat some years ago, ascended to the loftiest hermitage, that of St. Jerome, by the means of spiral steps hewn out in the rock on account of the steep acclivity. This, he observes, could not, in his time, be well accomplished by a stranger, without following the footsteps of an old ass, who carried from the convent a daily supply of food to the hermits. This animal having his two panniers stored with the provisions divided into portions, climbed without a guide, and having stopped at each of the cells, where the hermit took the portion allotted to him, returned back to the convent. He found that one of these hermits, to beguile the wearisomeness of his solitude, had contrived so effectually to tame the birds which frequented the groves surrounding his hermitage, that he could draw them together with a whistle, when they perched on his head, breast, and shoulders, taking the food from his mouth.

The convent is situated on the eastern side of the mountain, which seems to have been split by vast torrents of water, or by some violent convulsion of nature: in this way a platform has been formed in the cleft, sufficiently ample for the purpose of its construction. It is one of the forty-five religious houses of the Spanish congregation of the order of St. Benedict. The monks are bound to supply food and lodging for three days to all pilgrims who come up to pay their homage to the Virgin; besides which, they entertain the hermits on Sundays. The latter, who make a vow never to quit the mountain, take their stations by seniority, the junior hermit being placed at the greatest distance from the convent, and descending progressively as the vacancies happen. They are not altogether idle, taking pains to rival each other in making basket-work and other fanciful productions, which they display with great affability to their visitors. They assemble every morning to hear mass and perform divine service, in the parish church of St. Cecilia, which lies considerably above the convent; and twice a week they confess and communicate. They wear their beards long, and are clad in brown.

The church of St. Cecilia is a gloomy edifice, the gilding of which is much sullied by the smoke of eighty-five silver lamps, of various forms and sizes, suspended round the cornice of the sanctuary. For the supply of these with oil, funds have been bequeathed by devotees. The choir is decorated with wood carvings, curiously wrought, representing the most prominent passages in the life of Christ.

THE PEAK OF TENERIFFE.

[See cut below.]

[Illustration: THE PEAK OF TENERIFFE.]

The island of Teneriffe has received its present name from the inhabitants of the adjacent island Palma, in whose language =tener= signifies snow, and _iffe_, a hill. In extent, wealth, and fertility it exceeds all the other Canary islands. It continues to rise on all sides from the sea, until it terminates in the celebrated peak represented in the cut, which is, however, situated rather in the southern part

than in the center of the island. The ascent on the north side is more gradual than at the other parts, there being a space along the shore about three leagues in breadth, bounded on the sides by high mountains, or rather cliffs; but more inland it rises like a hanging garden all the way, without any considerable interruption of hills or valleys. The form of this island is triangular, extending itself into three capes, the nearest of which is about eighty leagues from the coast of Africa. In the middle it is divided by a ridge of mountains, which have been compared to the roof of a church, the peak forming the spire or steeple in the center.

The elevation of the peak of Teneriffe, according to the most accurate measurement, made by Cordier, is twelve thousand, one hundred and sixty-six feet, or nearly two miles and one-third above the level of the sea. In the ascent, the first eminence is called Monte Verde, or the green mountain, from the high fern with which it is covered, and presents a level plain of considerable extent. Beyond this is the mountain of pines, which are said to have formerly grown there in great abundance; but its steep sides are now craggy and barren, and its whole appearance very different from that of the eminence described above. After passing this summit, the traveler reaches a plain, on which the natives have bestowed the name of Mouton de Trigo, and upon which the peak in reality stands. It is a mountainous platform, rising more than seven thousand feet, or nearly a mile and a half, above the level of the sea; and here the currents of lava, hitherto concealed by the vegetation, begin to appear in all their aridity and confusion, a few lowly shrubs and creeping plants alone diversifying the surface of a desert, the most arid and rugged that can be imagined.

A small sandy platform of pumice-stones, bordered by two enormous currents of vitreous lava, and blocks of the same nature, ranged in a semicircle, forms what is called the station of the English, on account of the peak having been so often visited by British travelers. This platform is ninety-seven hundred and eighty-six feet, or upward of a mile and three-quarters above the level of the sea; and beyond it the acclivity is very steep, great masses of scoriæ, extremely rough and sharp, covering the currents of lava. Toward the summit, nothing but pumice-stone is to be seen. In fact the peak can only be ascended on the east and south-east sides. As it is impossible to get round the crater, the traveler's progress is arrested at the spot at which he reaches it. Here the two orders of volcanic substances are to be seen, the modern lavas being thrown up amid the ruins of ejections much more ancient, the immense masses of which constitute the platform on which the peak is placed. The shattered sides present a series of thick beds, almost all plunging toward the sea, composed alternately of ashes, volcanic sand, pumice-stones, lavas, either compact or porous, and scoriæ.

An incalculable number of currents, comparatively recent, which have descended from the peak, or have issued from its flanks, form irregular furrows, which run along the more ancient masses, and lose themselves in the sea to the west and north. Among these currents more than eighty craters are scattered, and augment with their ruins the confusion which prevails throughout.

The crater can alone be reached by descending down three chasms. Its sides are absolutely precipitous within, and are most elevated toward the north. Its form is elliptical; its circumference about twelve hundred feet; and its depth according to Cordier, one hundred and ten feet. Humboldt, however, estimates it at not more than from forty to sixty feet. The sides are, agreeably to the former of these observers, formed of an earth of snowy whiteness, resulting from the decomposition of the blackest and hardest vitreous porphyritic lava. All the rest is solid, and the lowest part occupied by blocks, which have fallen down from the sides. These solid parts are covered with shining crystals of sulphur, of a rhomboidal and octahedral figure, some of which are nearly an inch high, and are, perhaps, the finest specimens of native volcanic sulphur yet known. Vapors issue in abundance from among these blocks, and from an infinity of fissures which preserve a very intense heat. These vapors consist solely of sulphur and water, perfectly insipid. Beside the incrustations of sulphur, opal, in thin plates, is formed with great celerity. Humboldt regards the peak of Teneriffe as an enormous basaltic mountain, resting upon a dense secondary calcareous stone.

Various travelers have asserted, that the cold is intensely keen on the summit of the peak; that respiration is difficult; and that, particularly, spirituous liquors lose all their strength; which latter circumstance they ascribe to the spirit being more or less exposed to the sulphureous fumes exhaled from the crater. Cordier, and several other accurate observers, declare, however, that neither the smell nor the strength of liquids appeared, at this elevation, to be in the least degree impaired; and that volatile alkali, ether, and spirit of wine, possessed their usual pungency. They add, that the cold is very supportable; and that neither the aqueous sulphureous vapors, nor the rarity of the air, render breathing difficult.

We extract the following interesting particulars from Humboldt's account of his visit to Teneriffe.

"Toward three in the morning, by the sombrous light of a few fir torches, we began our expedition for the summit of the Piton. We scaled the volcano on the north-east, where the declivities are extremely steep; and came, after two hours' toil, to a small plain, which on account of its isolated situation, bears the name of Alta Vista. It is the station also of the Neveros, those natives whose

occupation it is to collect ice and snow, which they sell in the neighboring towns. Their mules, better practiced in climbing mountains than those hired by travelers, reach Alta Vista, and the Neveros are obliged to transport the snow to this place on their backs. Above this point the Malpays begins; a term by which is designated here, as well as in Mexico, Peru, and every other country subject to volcanoes, a ground destitute of vegetable mold, and covered with fragments of lavas.

“We observed, during the twilight, a phenomenon which is not unusual on high mountains, but which the position of the volcano we were scaling rendered very striking. A layer of white and fleecy clouds concealed from us the sight of the ocean, and the lower region of the island. This layer did not appear above sixteen hundred yards high; the clouds were so uniformly spread, and kept so perfect a level, that they wore the appearance of a vast plain covered with snow. The colossal pyramid of the peak, the volcanic summits of Lanzerota, of Fortaventura, and the isle of Palma, were like rocks amidst this vast sea of vapors, and their black tints were in fine contrast with the whiteness of the clouds.”

By an astronomical observation, made at the above elevation at sunrise, it was ascertained that the true horizon, that is, a part of the sea, was distant one hundred and thirty miles. Our traveler proceeds thus:

“We had yet to scale the steepest part of the mountain, the Piton, which forms the summit. The slope of this small cone, covered with volcanic ashes, and fragments of pumice-stone, is so steep, that it would have been almost impossible to reach the top, had we not ascended by an old current of lava, the wrecks of which have resisted the ravages of time. These wrecks form a wall of scorious rocks, which stretches itself into the midst of the loose ashes. We ascended the Piton by grasping these half-decomposed scoriæ, the sharp edges of which remained often in our hands. We employed nearly half an hour to scale a hill, the perpendicular hight of which does not exceed five hundred feet.

“When we gained the summit of the Piton, we were surprised to find scarcely room enough to seat ourselves conveniently. The west wind blew with such violence that we could scarcely stand. It was eight in the morning, and we were frozen with cold, though the thermometer kept a little above the freezing point.

“The wall, which surrounds the crater like a parapet, is so high, that it would be impossible to reach the Caldera, if on the eastern side there was not a breach, which seems to have been the effect of a flowing of very old lava. We descended through this breach toward the bottom of the tunnel, the figure of which is elliptical. The greatest breadth of the mouth appeared to us to be three hundred feet, the smallest two hundred feet.

“We descended to the bottom of the crater on a train of broken lava, from the eastern breach of the inclosure. The heat was perceptible only in a few crevices, which gave vent to aqueous vapors, with a peculiar buzzing noise. Some of these funnels or Crevices are on the outside of the inclosure, on the external brink of the parapet that surrounds the crater. We plunged the thermometer into them, and saw it rise rapidly to sixty-eight and seventy-five degrees.

“We prolonged in vain our stay on the summit of the peak, to wait the moment when we might enjoy the view of the whole of the archipelago of the Fortunate islands. We discovered Palma, Gomera, and the Great Canary, at our feet. The mountains of Lanzerota, free from vapors at sunrise, were soon enveloped in thick clouds. On a supposition only of an ordinary refraction, the eye takes in, in calm weather, from the summit of the volcano, a surface of the globe of fifty-seven hundred square leagues, equal to a fourth of the surface of Spain.

“Notwithstanding the heat we felt in our feet on the edge of the crater, the cone of ashes remains covered with snow during several months in the winter. It is probable, that under the cap of snow considerable hollows are found, like those we find under the glaciers of Switzerland, the temperature of which is constantly less elevated than that of the soil on which they repose. The cold and violent wind which blew from the time of sunrise, engaged us to seek shelter at the foot of the Piton. Our hands and faces were frozen, while our boots were burnt by the soil on which we walked. We descended in the space of a few minutes the sugar-loaf, which we had scaled with so much toil; and this rapidity was in part involuntary, for we often rolled down on the ashes. It was with regret that we quitted this solitary place, this domain where Nature towers in all her majesty.”

To the above we subjoin the following extract from the account published in the first volume of the Transactions of the Geological Society, by the Hon. Mr. Bennet.

At the distance of thirty-four leagues from the island, Mr. Bennet had a very distinct view of the peak, rising like a cone from the bed of the ocean. The rocks and strata of Teneriffe, he observes, are wholly volcanic, the long chain of mountains, which may be termed the central chain, traversing the island from the foot of the second region of the peak, and sloping down on the eastern,

western and northern sides, to the sea. Toward the south, or more properly the south-south-west, the mountains are nearly perpendicular, and though broken into ridges, and occasionally separated by deep ravines, that are cut transversely as well as longitudinally, there are none of those plains, nor that gradual declination of strata, which the south-eastern and north-western sides of the island exhibit.

Mr. Bennet ascended the peak in the month of September, 1810. We give the abridged details of this expedition in his own words.

“The road to the city of Orotava, is a gradual and easy slope for three or four miles, through a highly cultivated country. Leaving the town, after a steep ascent of about an hour, through a deep ravine, we quitted the cultivated part, and entered into forests of chestnuts, the trees of which are of a large size. The form of this forest is oblong; the soil is deep, and formed of decomposed lava, small ash and pumice. I examined several channels in the strata, or ravines worn by the rains, and there was no appearance of any other rock. Leaving this forest, the track passes over a series of green hills, which we traversed in about two hours, and at last halted to water our mules at a spot where there is a small spring of bad and brackish water issuing from a lava rock. The ravine is of considerable depth. The range of green hills extends a mile or two further, the soil shallowing by degrees, until at length the trees and shrubs gradually dwindling in size, the Spanish broom alone covers the ground. Leaving behind us this range of green hills, the track, still ascending, leads for several hours across a steep and difficult mass of lava-rock, broken here and there into strange and fantastic forms, worn into deep ravines, and scantly covered in places by a thin layer of yellow pumice. As we proceeded on our road, the hills on our left gradually rose in hight, till the summits were lost in those of the central chain; while, on our right, we were rapidly gaining an elevation above the lower range of the peak. We met with several small conical hills, or mouths of extinct volcanoes, the decomposed lava on the edges of the craters having a strong red ochreous tint. At length, an immense undulated plain spreads itself like a fan, on all sides, nearly as far as the eye can reach. This plain is bounded on the west-south-west and south-south-west, by the regions of the peak; and on the east and north-east, by a range of steep perpendicular precipices and mountains, many leagues in circumference, called by the Spaniards =Las Faldas=. On this plain, or desert, for we had long left all show of vegetation, except a few stunted plants of Spanish broom, a sensible change was felt in the atmosphere; the wind was keen and sharp, and the climate like that of England in the months of autumn. All here was sad, silent and solitary. We saw at a distance the fertile plains on the coast, lying as it were under our feet, and affording a cheerful contrast to the scenes of desolation with which we were surrounded. We were already seven or eight thousand feet above the level of the sea, and had reached the bottom of the second region of the peak.

“Having reached the end of the plain, we found ourselves at the bottom of a steep hill, at the foot of which is a mass or current of lava. After a laborious, not to say hazardous ascent of about an hour, the pumice and ash gave way, and the mules sinking knee-deep at every step, we arrived at about five in the afternoon at the other extremity of the stream of lava, which, descending from the summit of the second region of the peak, divides at the foot of the cone into two branches, the one running to the north-east, and the other to the north-west. It was here we were to pass the night; so, lighting a fire made of dry branches of the Spanish broom, and stretching a part of a sail over a portion of the rock, we ate our dinner and laid ourselves down to sleep. I, however, passed the best part of the night by the fire, the weather being piercingly cold. As I stood by the fire, the view all around me was wild and terrific; the moon rose about ten at night, and, though in her third quarter, gave sufficient light to show the waste and wilderness by which we were surrounded. The peak and the upper regions which we had yet to ascend, towered awfully above our heads, while below, the mountains that had appeared of such a hight in the morning, and had cost us a day’s labor to climb, lay stretched as plains at our feet. From the uncommon rarity of the atmosphere, the whole vault of heaven appeared studded with innumerable stars, while the valleys of Orotava were hidden from our view by a thin vail of light fleecy clouds, that floated far beneath the elevated spot we had chosen for our resting-place; the solemn stillness of the night was only interrupted by the crackling of the fire round which we stood, and by the whistling of the wind, which coming in hollow gusts from the mountain, resembled the roar of distant cannon.

“Between two and three in the morning, we resumed, on foot, our ascent of the mountain, the lower part of which we had climbed on horseback the preceding evening; the ascent, however, became much more rapid and difficult, our feet sinking deep in the ashes at every step. From the uncommon sharpness of the acclivity, we were obliged to stop often to take breath: after several halts, we at last reached the head of the pumice hill. After resting some short time here, we began to climb the stream of lava, stepping from mass to mass. The ascent is steep, painful and hazardous; in some places the stream of lava is heaped up in dykes or embankments; and we were obliged to clamber over them as one ascends a steep wall.

“We halted several times during the ascent, and at last reached a spot called La Cueva, one of the numerous caves that are found on the sides of the mountain; this is the largest of them, and is filled with snow and the most delicious water, which was just at the

point of congelation. The descent into it is difficult, it being thirty or forty feet deep. One of our party let himself down by a rope: he could not see the extent of the cave, but the guides declared it to be three hundred feet in length, and to contain thirty or forty feet of water in depth. The roof and sides are composed of a fine stalactitic lava, similar to that found on Vesuvius, and it is of the same nature as that which flowed on the surface. We rested here about half an hour, during which we had an opportunity of observing the rising of the sun, and that singular and rapid change of night into day, which is the consequence of an almost entire absence of twilight. As we ascended the north-east side of the mountain, this view was strikingly beautiful: at first there appeared a bright streak of red on the horizon, which gradually spread itself, lighting up the heavens by degrees, and growing brighter and brighter, till at last the sun burst forth from the bed of the ocean, gilding as it rose the mountains of Teneriffe, and those of the Great Canary; in a short time the whole country to the eastward lay spread out as a map. The Great Canary was easily to be distinguished; and its rugged and mountainous character, similar to that of the other islands, became visible to the naked eye. The cold at this time was intense, the wind keen and strong, and the thermometer sunk to thirty-two degrees. After a short though rapid ascent, we reached the summit of the second stage of the mountain, passing over a small plain of white pumice, on which were spread masses of lava, and at length arrived at the foot of the cone. This division of the mountain forms what is generally termed the peak of Teneriffe: it represents the present crater of Vesuvius, with this difference, however, that while the surface of that mountain is composed of a black cinder or ash, the superfices of this appear to be a deposit of pumice of a white color, of scoriæ and lava, with here and there considerable masses that were probably thrown out when the volcano was in action. Numerous small cavities on the side of the mountain emitted vapor, with considerable heat. Here begins the only fatiguing part of the ascent; the steepness of the cone is excessive; at each step our feet sunk into the ash, and large masses of pumice and lava rolled down from above; we were all bruised, and our feet and legs were cut, but not materially hurt: at last we surmounted all difficulties, and seated ourselves on the highest ridge of the mountain. This uppermost region does not appear to contain in superficies more than an acre and a half, and is itself a small crater, the walls of which are the different points on which we sat, and are plainly visible from below. Within, the lava is in the most rapid state of decomposition. The surface is hot to the feet, and the guides said it was dangerous to remain long in one spot: as it was, some of us sunk to our knees in the hot deposit of sulphur. Upon striking the ground with the feet, the sound is hollow, similar to what is produced by the same impulsion on the craters of Vesuvius and Solfaterra. I estimate the depth of the crater to be, from the highest ridge to the bottom, about two hundred feet, forming an easy and gradual descent.

“The view from the summit is stupendous: we could plainly discover the whole form of the island, and we made out distinctly three or four of the islands, which, collectively, are called the Canaries; we could not, however, see Lancerotte or Fuerteventura, though we were told that other travelers had distinguished them all.

“From this spot, the central chain of mountains that run from south-west to north-east, is easily to be distinguished. These, with the succession of fertile and woody valleys, commencing from San Ursula, and ending at Las Horcas, with the long line of precipitous lava rocks that lay on the right of our ascent, and which traverse that part of the island running from east to west, from their point of departure at the Canales, to where they end in an abrupt headland on the coast, with their forests, and villages, and vineyards, the port with the shipping in the roads, the town of Orotava, with its spires glittering as the morning sun burst upon them, afford a cheerful contrast to the streams of lava, the mounds of ash and pumice, and the sulphurated rock on which we had taken our seat. The sensation of extreme hight was in fact one of the most extraordinary I ever felt; and though I did not find the pain in my chest arising from the rarity of the atmosphere, by any means so acute as on the mountains of Switzerland, yet there was a keenness in the air, independent of the cold, that created no small uneasiness in the lungs. The respiration became short and quick, and repeated halts were found necessary. The idea also of extreme hight was to me more determinate and precise than on the mountains of Switzerland; and though the immediate objects of vision were not so numerous, yet as the ascent is more rapid, the declivity sharper, and there is here no mountain like Mont Blanc towering above you, the twelve thousand feet above the level of the sea appeared considerably more than a similar elevation above the lake of Geneva. We remained at the summit about three-quarters of an hour, our ascent having cost us the labor of four hours, as we left La Estancia at ten minutes before three, and reached the top of the peak before seven. Our thermometer, which was graduated to the scale of Fahrenheit, was, during our ascent, as follows: at Orotava, at eight in the morning, seventy-four degrees; at six in the evening, at La Estancia, fifty degrees; at one, in the following morning, forty-two degrees; at La Cueva, at half past four, thirty-two degrees; at the bottom of the cone, thirty-six degrees; at the top of the peak, one hour and a half after sunrise, thirty-three degrees. The descent down the cone is difficult, from its extreme rapidity, and from the fall of large stones, which loosen themselves from the beds of pumice. Having at last scrambled to the bottom, we pursued our march down the other course of the lava, that is to say, down its westerly side, having ascended its eastern. The ravines and rents in this stream of lava are deep and formidable; the descent into them is always painful and troublesome, often dangerous: in some places we let ourselves down from rock to rock. I can form no opinion why there should

be these strange irregularities in the surface of this lava; in places it resembles what sailors term the trough of the sea, and I can compare it to nothing but as if the sea in a storm, had by some force become on a sudden stationary, the waves retaining their swell. As we again approached La Cueva, we came to a singular steep valley, the depth of which, from its two sides, can not be less than one hundred to one hundred and fifty feet, the lava lying in broken ridges one upon the other, similar to the masses of granite rock that time and decay have tumbled down from the top of the Alps; and, except from the scoriæ, or what Milton calls 'the fiery surge,' they in no degree bear the marks of having rolled as a stream of liquid matter.

"We descended the pumice hill with great rapidity, almost at a run, and arrived at La Estancia in little more than two hours. We then mounted our mules, and following the track by which we had ascended the preceding day, we reached, about four o'clock, the country-house from which we had started."

The first eruption of which there is any distinct account, occurred on the twenty-fourth of December, 1704, when twenty-nine shocks of an earthquake were distinctly felt. On the thirty-first a great light was observed on Manja, toward the White mountains. Here the earth opened, and two volcanoes were formed, which threw up such heaps of stones as to raise two considerable mountains: the combustible matter, which still continued to be thrown up, kindled above fifty fires in the vicinity. The whole country for three leagues round was in flames, which were increased by another volcano opening by at least thirty different vents within the circumference of half a mile. On the second of February following, another volcano broke out in the town of Guimar, swallowing up a large church.

A subsequent eruption in 1706 filled up the port of Guarachico. The lava, in its descent, ran five leagues in six hours; and on this lava, houses are now built where ships formerly rode at anchor. Neither of these eruptions was from the crater on the summit of the peak, for that has not ejected lava for centuries, and it now issues from the flanks only. The last eruption was on the ninth of June, 1798, and was very terrible. Three new mouths opened at the hight of eighty-one hundred and thirty feet, or upward of a mile and a half above the level of the sea, upon the inclined slope of the base of the peak toward the south-west. Above this, at the hight of ten thousand, two hundred and forty feet, or nearly two miles, M. Cordier found a vast crater nearly four miles and a half in circumference, which lie ascertained to be very ancient. Its sides are extremely steep, and it still presents the most frightful picture of the violence of subterraneous fire. The peak rises from the sides of this monstrous aperture. To the south-west is the mountain of Cahora, which is said to have become a volcano in 1797. The other mountains of Teneriffe, which tradition reports to have been formerly volcanoes, are Monte Roxo, or the red mountain; several mountains, called the Malpasses, lying to the eastward; and one (Rejada) in a southern direction. Throughout the whole of the distance between Monte Roxo and the bay of Adexe, according to Mr. Glass, the shore is about twenty-five hundred feet, or nearly half a mile in hight, and perpendicular as a wall. The southern coast has a much superior elevation, the chain of mountains by which it is bounded being, agreeably to St. Vincent, eighty-three hundred and twenty feet, or more than a mile and a half, above the level of the sea.

THE SOUFFRIERE MOUNTAIN.

This volcanic mountain, the dreadful eruption of which we are about to describe, is the most elevated and most northerly of the lofty chain running through the West India island of St. Vincent. From the extraordinary frequency and violence of the earthquakes, which in 1811, are calculated to have exceeded two hundred, some great movement or eruption was looked for. In the interim the mountain indicated much disquietude; but the apprehension was not so immediate as to restrain curiosity, or to prevent repeated visits to the crater, which had latterly been more numerous than ever. Even on the twenty-sixth of April, 1812, the day preceding the eruption, several gentlemen ascended and remained there for some time. Nothing unusual was then remarked, nor any external difference observed, except rather a stronger emission of smoke from the interstices of the conical hill, at the bottom of the crater. To those who have not visited this romantic and wonderful spot, a slight description of it, as it lately stood, is previously necessary.

"About two thousand feet from the level of the sea, on the south side of the mountain, and at rather more than two-thirds of its hight, opens a circular chasm, somewhat exceeding half a mile in diameter, and between four hundred and five hundred feet in depth. Exactly in the center of this capacious bowl, rose a conical hill about two hundred and sixty or three hundred feet in hight, and about two hundred in diameter, richly covered and variegated with shrubs, brushwood and vines, above half-way up, and the remainder covered over with virgin sulphur to the top. From the fissures of the cone and interstices of the rocks, a thin white smoke was constantly emitted, occasionally tinged with a slight bluish flame. The precipitous sides of this magnificent amphitheater were fringed with various evergreens and aromatic shrubs, flowers, and many alpine plants. On the north and south sides of the base of the cone were two pieces of water, one perfectly pure and tasteless, the other strongly impregnated with sulphur and alum. This lonely and beautiful spot was rendered more enchanting by the singularly melodious notes of a bird, an inhabitant of these upper

solitudes, and altogether unknown to the other parts of the island, hence principally called or supposed to be invisible, though it certainly has been seen, and is a species of blackbird.

“A century had now elapsed since the last convulsion of the mountain, or since any other elements had disturbed the serenity of this wilderness, besides those which are common to the tropical tempest. It apparently slumbered in primeval solitude and tranquillity, and from the luxuriant vegetation and growth of the forest, which covered its side from the base nearly to the summit, seemed to discountenance the fact, and falsify the records of the ancient volcano. Such was the majestic, peaceful Souffriere, on April the twenty-seventh; but our imaginary safety was soon to be confounded by the sudden danger of devastation. Just as the plantation bell rang at noon on that day, an abrupt and dreadful crash from the mountain, with a severe concussion of the earth, and tremulous noise in the air, alarmed all around it. The resurrection of this fiery furnace was proclaimed in a moment by a vast column of thick, black, ropy smoke, like that of an immense glass-house, bursting forth at once, and mounting to the sky; showering down sand, gritty calcined particles of earth and ashes mixed, on all below. This, driven before the wind toward Wallibou and Morne Ronde, darkened the air like a cataract of rain, and covered the ridges, woods and cane-pieces with light gray-colored ashes, resembling snow when slightly covered by dust. As the eruption increased, this continual shower expanded, destroying every appearance of vegetation. At night a very considerable degree of ignition was observed on the lips of the crater; but it is not asserted that there was as yet any visible ascension of flame. The same awful scene presented itself on the following day; the fall of ashes and calcined pebbles still increasing, and the compact, pitchy column from the crater rising perpendicularly to an immense hight, with a noise at intervals like the muttering of distant thunder.

“On Wednesday, the twenty-ninth, all these menacing symptoms of horror and combustion still gathered more thick and terrific for miles around the dismal and half-obscured mountain. The prodigious column shot up with quicker motion, dilating as it rose like a balloon. The sun appeared in total eclipse, and shed a meridian of twilight over us, that aggravated the wintry gloom of the scene, now completely powdered over with falling particles. It was evident that the crisis was yet to come, that the burning fluid was struggling for a vent, and laboring to throw off the superincumbent strata and obstructions, which suppressed its torrent. At night, it was manifest that it had greatly disengaged itself from its burden, by the appearance of fire flashing above the mouth of the crater.

“On the memorable thirtieth of April, the reflection of the rising sun on this majestic body of curling vapor was sublime beyond imagination: any comparison of the Glaciers, or of the Andes, can but feebly convey an idea of the fleecy whiteness and brilliancy of this awful column of intermingled and wreathed smoke and clouds. It afterward assumed a more sulphureous cast, like what are called thunder-clouds, and in the course of the day had a ferruginous and sanguine appearance, with a much livelier action in the ascent, and a more extensive dilatation, as if almost freed from every obstruction. In the afternoon, the noise was incessant, and resembled the approach of thunder still nearer and nearer, with a vibration that affected the feelings and hearing: as yet there was no convulsive motion, or sensible earthquake. The Charaibs settled at Morne Ronde, at the foot of the Souffriere, abandoned their houses, with their live stock, and everything they possessed, and fled precipitately toward town. The negroes became confused, forsook their work, looked up to the mountain, and, as it shook, trembled, with the dread of what they could neither understand or describe: the birds fell to the ground, overpowered with showers of ashes, unable to keep themselves on the wing; the cattle were starving for want of food, as not a blade of grass or a leaf was now to be found; the sea was much discolored, but not uncommonly agitated; and it is remarkable, that throughout the whole of this violent disturbance of the earth, it continued quite passive, and did not at any time sympathize with the agitation of the land. About four o’clock in the afternoon, the noise became more alarming, and just before sunset the clouds reflected a bright copper color, suffused with fire. Scarcely had the day closed, when the flames burst at length pyramidically from the crater, through the mass of smoke; the rolling of the thunder became more awful and deafening; electric flashes quickly succeeded, attended with loud claps; and now, indeed, the tumult began. Those only who have witnessed such a sight, can form any idea of the magnificence and variety of the lightning and electric flashes; some forked and zigzag, playing across the perpendicular column from the crater; others shooting upward from the mouth like rockets of the most dazzling luster; others like shells, with their trailing fuses, flying in different parabolas, with the most vivid scintillations, from the dark sanguine column, which now seemed inflexible, and immovable by the wind. Shortly after seven in the afternoon, the mighty caldron was seen to simmer, and the ebullition of lava to break out on the north-west side. This, immediately after boiling over the orifice, and flowing a short way, was opposed by the acclivity of a higher point of land, over which it was impelled by the immense tide of liquefied fire which drove it on, forming the figure V in grand illumination. Sometimes, when the ebullition slackened, or was insufficient to urge it over the obstructing hill, it recoiled like a refluent billow, from the rock, and then again rushed forward, impelled by fresh supplies, and, surmounting every obstacle, carried rocks and woods together, in its course down the slope of the mountain, until it precipitated itself down some vast ravine, concealed from our sight by the intervening ridges of Morne Ronde. Vast globular bodies of fire were seen projected from the fiery furnace, and, bursting, fell back into it, or over it upon the

surrounding bushes, which were instantly set in flames. About four hours from the time of the lava's boiling over the crater, it reached the sea, as we could observe from the reflection of the fire and electric flashes attending it. About half past one, the following morning, another stream of lava was seen descending to the eastward toward Rabacca. The thundering noise of the mountain, and the vibration of sound that had been so formidable hitherto, now mingled in the sudden monotonous roar of the rolling lava, became so terrible, that dismay was almost turned into despair. At this time the first earthquake was felt; this was followed by showers of cinders, which fell with the hissing noise of hail, during two hours.

"At three o'clock, a rolling on the roofs of the houses indicated a fall of stones, which soon thickened, and at length descended in a rain of intermingled fire, which threatened at once the fate of Pompeii or Herculaneum. The crackling coruscations from the crater at this period exceeded all that had yet passed. The eyes were struck with a momentary blindness, and the ears stunned with a confusion of sounds. People sought shelter in the cellars, under rocks, or anywhere, for every place was nearly the same; and the miserable negroes, flying from their huts, were knocked down, or wounded, and many killed in the open air. Several houses were set on fire. The estates situated in the immediate vicinity, seemed doomed to destruction. Had the stones which fell been heavy in proportion to their size, not a living creature could have escaped death: these, having undergone a thorough fusion, were divested of their natural gravity, and fell almost as light as pumice, though in some places as large as a man's head. This dreadful rain of stones and fire lasted upward of an hour, and was again succeeded by cinders from three till six o'clock in the morning. Earthquake followed earthquake, almost momentarily; or rather the whole of this part of the island was in a state of continued oscillation; not agitated by shocks vertical or horizontal; but undulated like water shaken in a bowl.

"The break of day, if such it could be called, was truly terrific. Utter darkness prevailed till eight o'clock, and the birth of May dawned like the day of judgment: a chaotic gloom enveloped the mountain, and an impenetrable haze hung over the sea, with black sluggish clouds of a sulphureous cast. The whole island was covered with cinders, scoriæ, and broken masses of volcanic matter. It was not until the afternoon, that the muttering noise of the mountain sunk gradually into a solemn yet suspicious silence. Such are the particulars of this sublime and tremendous scene, from its commencement to its catastrophe."

PETER BOTTE'S MOUNTAIN.

[See cut, page 74.]

The singular peak represented in the cut, is in the island of Mauritius, which lies in the Indian ocean, east of Madagascar. The island is about one hundred and forty miles in circuit, and produces rice, sugar, cloves, indigo, and various tropical fruits. It was first settled by the Dutch; but the French gained possession of it in 1715. In 1810, the English took it, and it is still held by them. The island seems to have been thrown up from the sea by volcanic eruptions, as it everywhere bears marks of convulsions by inward fires. In its central parts are wild craggy mountains, the summits of which are always covered with snow. And among these is the peak represented in the cut, which is eighteen hundred feet in hight, and surrounded by dismal ravines. It is called Peter Botte's mountain, from a legend that a man of that name once ascended to the top. The general belief, however, is, that it was never ascended till the year 1832, when the top of it was reached by a party under Capt. Lloyd, an English engineer. The exploit was one of the most hazardous, and the account of it is almost painful to the reader, from the evident peril of the adventurers.

[Illustration: PETER BOTTE'S MOUNTAIN.]

KILAUEA.

While on the subject of wonderful volcanoes, we must not omit to notice one that has been called the "Niagara of volcanoes," and the "king of volcanoes," =viz.=, Kilauea, the great volcano of the Sandwich islands, which is on the island of Hawaii, about thirty miles from Hilo bay. One of the missionaries, from whom we have the account, started to visit it on horseback; but the way being rough and the animal unshod, he severely felt the inconvenience of the lava, became discouraged, and moved so slowly, that he was given up, and the missionary and his associate proceeded on foot.

"Toward evening," he continues, "we reached Olaa, an inland settlement; and the next day, before noon, had arrived at an elevation of some four thousand feet, at a distance of twenty miles from Hilo bay.

"Approaching the great crater of Kilauea, we had a fine view of the magnificent dome of Mauna Loa, stretching on some twenty miles beyond it, and rising above it to the lofty hight of ten thousand feet. Evidences of existing volcanic agency multiplied around us; steam, gas and smoke, issued from the sulphur banks on the north-east and south-east sides of the crater, and here and there, from deep and extended fissures connected with the fiery subterranean agency; and as we passed circumspectly along the

apparently depressed plain that surrounds the crater, we observed an immense volume of smoke and vapor ascending from the midst of it. At the same time, and from the same source, various unusual sounds, not easily described or explained, fell with increasing intensity on the ear. Then the angry abyss, the fabled habitation and throne of _Pele_, the great idol goddess whom the Hawaiians formerly worshiped, opened before us.

“Coming near to the rim, I fell upon my hands and knees, awe-struck, and crept cautiously to the rocky brink; for with all my natural and acquired courage, I was unwilling at once to walk up to the giddy verge, and look down upon the noisy, fiery gulf beneath my feet. Shortly, however, I was able to stand very near, and gaze upon this wonder of the world, which I wish I could set before my readers, in all its mystery, magnitude and grandeur. It is not a lofty cone, or mountain-top pointing to the heavens, but a vast chasm in the earth, five or six times the depth of Niagara falls, and seven or eight miles in circumference. It is situated on the flank of a vast mountain, which has been gradually piled up by a similar agency during the course of ages. Such is the immense extent and depth of Kilauea, that it would take in, entire, the city of Philadelphia or New York, and make their loftiest spires, viewed from the rim, appear small and low. But neither cities nor meadows, nor water nor vegetation, can be found in this chief of the deep places of the earth, but a lake of lava, some black and indurated, some fiery and flowing, some cooling as a floating bridge over the fathomless molten abyss, seven times hotter than Nebuchadnezzar’s hottest furnace, and some bursting up through this temporary incrustation, rending it here and there, and forming mounds and cones upon it. The immense mass, laboring to escape, pressed against the great crater’s sides, which consist not of a frail ‘Chinese wall,’ built by human hands to resist human strength, but an irregularly elliptical wall of basaltic rocks, extending a thousand feet above the surface of the lava lake, and to unknown depths below. Six hundred feet below, the verge stretches around horizontally, a vast amphitheater gallery of black indurated lava, once fluid but now solid, and on which an army of a hundred thousand men might stand to view the sublime spectacle beneath, around, and above them.

“While through the eye, the impressions of grandeur, strong at first, increased till the daylight was gone, the impressions received through the ear, were peculiar, and by no means inconsiderable. The fiercely whizzing sound of gas and steam, rushing with varying force through obstructed apertures in blowing cones, or cooling crusts of lava, and the laboring, wheezing, struggling, as of a living mountain, breathing fire and smoke and sulphurous gas from his lurid nostrils, tossing up molten rocks or detached portions of fluid lava, and breaking up vast indurated masses with varied detonations, all impressively bade us stand in awe. When we reached the verge, or whenever we came from a little distance to look over, these strange sounds increased, as if some intelligent power, with threatening tones and gestures, indignant at our obtrusiveness, were forbidding us to approach. The effect of all this on aboriginal visitors, before the true God was made known to them, may have been to induce or confirm the superstition, that a deity or family of deities dwelt there, and recognized the movements of men, and in various ways expressed anger against them. If my native fellow-travelers had not been cured of their superstition, or had not known me to be opposed to all idolatry, and particularly to the worship of Pele, the goddess whom they once supposed dwelt there, they might naturally have mistaken my almost involuntary prostration, as an act of religious homage to this discarded Hawaiian deity. But the missionaries had set at naught the _tabus_ of this deity, and Kapiolani had openly invaded the same, and descending into this crater had, in a fearless and Christian manner, there acknowledged Jehovah as the only true God, and proclaimed to her countrymen that this was but one of the fires which he has kindled and controls. So that the natives now with me were ready devoutly to acknowledge all this.

“When seven years before our visit, Messrs. Ellis, Thurston, Bishop and Goodrich, accompanied by Mr. Harwood, visited this yawning gulf, they said of it: ‘The bottom was filled with lava, and the south-west and northern parts of it were one vast flood of liquid fire, in a state of terrific ebullition, rolling to and fro its fiery surge and flaming billows. Fifty-one craters of various forms and sizes, rose, like so many conical islands from the surface of the burning lake. Twenty-two constantly emitted columns of gray smoke and pyramids of brilliant flame, and many of them at the same time vomited from their ignited mouths, streams of fluid lava, which rolled in blazing torrents down their black, indented sides, into the boiling mass of fire below.’ The surface of this body of lava is subject to unceasing changes from year to year; for ‘deep calleth unto deep’ continually, and the fiery billows of this troubled ocean never rest.

“As night came on we took our station on the north side of the very brink, where we supposed we should be able most securely and satisfactorily to watch the action of this awful laboratory during the absence of the light of the sun. Though the spot where we spread our blanket for a lodgment had been considered as the safest in the neighborhood, there was room for the feeling of insecurity which some who had preceded us have thus described. ‘The detachment of one small stone beneath, or a slight agitation of the earth, would have precipitated us, amid the horrid crash of falling rocks, into the burning lake.’ Had I thought the danger so imminent, I should have deemed it prudent to take a position somewhat further off. The mass which supported us had doubtless

been shaken a thousand times, and was liable every hour to be shaken again; but being in the short curvature of the crater, like the key-stone of an arch, it could not easily be thrown from its position by any agitation that would naturally occur while this great safety-valve is kept open, or the numerous fissures round it, reaching to the very bowels of the mountain, convey harmlessly from unknown depths, gases and volumes of steam, generated where water comes in contact with intense volcanic heat. Our position was about four thousand feet above the level of the sea, and one thousand above the surface of the lake below us.

“The great extent of the surface of this lava lake; the numerous places in it where the fiery element was displaying itself; the conical mouths here and there discharging glowing lava overflowing and spreading its waves around, or belched out in detached and molten masses that were shot forth with detonations, perhaps by the force of gases struggling through from below the surface, while the vast column of vapor and smoke ascended up toward heaven, and the coruscations of the emitted brilliant lava, illuminating the clouds that passed over the terrific gulf, all presented by night a splendid and sublime panorama of volcanic action, probably nowhere surpassed, if ever equaled, and which to be imagined must be seen. Had Vulcan employed ten thousand giant Cyclops, each with a steam-engine of a thousand horse-power, blowing anthracite coal for smelting mountain minerals, or heaving up and hammering to pieces the everlasting rocks and hills, their united efforts would but begin to compare with the work of Pele here.

“There was enough of mystery connected with the wonderful experiments going on before our eyes, to give ample employment to fancy and philosophy, and materially to enhance the sublimity of the fearful scene. For it might be asked, how can such an immense mass of rocks and earth be kept incessantly in a state of fusion without fuel or combustion? Or by what process could such solid masses be fused at all, in accordance with any mode of generating heat with which we are acquainted? If there be combustion in the crater adequate to the melting of such vast masses of substances so hard, rocky and earthy, why is there an accumulation and increase of the general mass, so that millions of cubic fathoms are, from time to time, added to the solid contents of the mountain? But if the bowels of the mountain are supposed to be melted by intense heat in some way generated, could they be heaved up by the expansion of steam or gas, while an orifice equal to three or four square miles, like that of Kilauea, or the terminal crater on the same mountain, is kept open; for steam and gas might be supposed to pass through the fluid masses and escape, instead of raising them from a depth, just as steam issues from the bottom of a boiling caldron, without materially elevating the surface of its contents.

“But if with one class of geologists, we suppose the interior of the earth to be in a molten and fluid state, as perhaps originally created, and that Kilauea and other volcanoes are but the openings and safety-valves of that subterranean, fiery, central ocean of red or white-hot matter, then we have here no faint illustration of the bold imagery used by the sacred writers, and of their phraseology, which to some seems hyperbolical and even paradoxical, as when they speak of the ‘bottomless pit,’ the ‘fire that is not quenched,’ ‘the lake that burneth with fire and brimstone,’ ‘the smoke of their torment which ascendeth up forever and ever.’ If such a vast mass of fiery fluid constitutes the main portion of the interior of the earth, it is literally ‘bottomless;’ and the opened surface, like that of Kilauea, may be strictly called a ‘lake of fire;’ and as sulphur and particles of the sulphuret of iron are present, it may well be called ‘a lake that burns with fire and brimstone.’

“After gazing at the wonderful and wonderfully sublime scene for some twenty hours, taking but a little time for repose, we found the sense of fear subsiding, and curiosity prompting to a closer intercourse with Pele, and a more familiar acquaintance with her doings and habits. Many who try the experiment, though at first appalled, are ready after a few hours, to wend their way down the steep sides of the crater. Thus we descended into the immense pit from the north-east side, where it was practicable, first to the black ledge or amphitheater gallery, and thence to the surface of the lava lake. This we found extremely irregular, presenting cones, mounds, plains, vast bridges of lava recently cooled, pits and caverns, and portions of considerable extent in a movable and agitated state. We walked over lava which, by some process, had been fractured into immensely large slabs, as though it had been contracted by cooling, or been heaved up irregularly by the semi-fluid mass below. In the fissures of this fractured lava, the slabs or blocks two feet below the surface, were red-hot. A walking-stick thrust down would be set on fire and flame instantly.

“Passing over many masses of such lava, we ventured toward the more central part of the lake, and came near to a recent mound which had probably been raised on the cooling surface, after our arrival the day before. From the top of it flowed melted lava, which spread itself in waves to a considerable distance, one side or the other, all around. The masses thrown out in succession moved sluggishly, and as they flowed down the inclined plane, a crust was formed over them, which darkened and hardened, and became stationary, while the stream still moved on below it. The front of the mass, red-hot, passed along down, widening and expanding itself, and forcing its way through a net-work, as it were, of irregular filaments of iron, which the cooling process freely supplied. This motion of a flowing mass, whether smaller or larger, seen from the rim of the crater by night, gives the appearance of a fiery

surf, or a rolling wave of fire, or the dancing along of an extended semicircular flame on the surface of the lake. When one wave has expended itself, or found its level, or otherwise become stationary, another succeeds and passes over it in like manner, and then another, sent out as it were, by the pulsations of the earth's open artery, at the top of the mound. This shows how a mound, cone, pyramid, or mountain, can be gradually built of lava, and wide plains covered at its base with the same material.

"We approached near the border of some of these waves, and reached the melted lava with a stick two yards long; and thus obtained several specimens red-hot from the flowing mass. I have since had occasion to be surprised at the absence of fear in this close contiguity with the terrible element, where the heat under our feet was as great as our shoes would bear, and the radiating heat from the moving mass was so intense that I could face it only a few seconds at a time at a distance of two or three yards. Yet having carefully observed its movements awhile, I threw a stick of wood upon the thin crust of a moving wave where I believed it would bear me, even if it should bend a little, and stood upon it a few moments. In that position, thrusting my cane down through the cooling, tough crust, about half an inch thick, I withdrew it, and forthwith there gushed up of the melted, flowing lava under my feet, enough to form a globular mass two and a half or three inches in diameter, which, as it cooled, I broke off and bore away as spoils from the ancient domain and favorite seat of the great idol goddess of the Hawaiians. Parts that were in violent action we dared not approach.

"There is a remarkable variety in the volcanic productions of Hawaii; a variety as to texture, form and size, from the vast mountain and extended plain, to the fine-drawn and most delicate vitreous fiber, the rough clinker, the smooth stream, the basaltic rock, and masses compact and hard as granite or flint, and the pumice or porous scoriæ, or cinders, which, when hot, probably formed a scum or foam on the surface of the denser molten mass. Considerable quantities of capillary glass are produced at Kilauea, though I am not aware that the article is found elsewhere on the islands. Its production has been deemed mysterious. In its appearance it resembles human hair, and among the natives is familiarly called '=Lauoho o Pele=,' the hair of Pele. It is formed, I presume, by the tossing off of small detached portions of lava of the consistence of melted glass, from the mouths of cones, when a fine vitreous thread is drawn out between the moving portion, and that from which it is detached. The fine-spun product is then blown about by the wind, both within and around the crater, and is collected in little locks or tufts.

"Sulphur is seen, but in small quantities, in and around the crater; and at a little distance from the rim there are yellow banks, on which beautiful crystals of sulphur may be found. In one place, a pool of pure distilled water, condensed from the steam that rises from a deep fissure, affords the thirsty traveler a beverage far better than that of the ordinary distiller. There is, however, a kind of sulphurous gas produced by the volcano, which is highly deleterious if breathed often or freely. This is one source of danger to the visitor, which, while I was down a thousand feet below the rim, produced a temporary coughing.

"I was, perhaps, too venturesome, but other visitors have been far more so. As one instance of this, Dr. Judd, having become familiar with the volcanic power, in his ardor to secure valuable and recent specimens for the United States exploring expedition, on the visit of Commodore Wilkes and his company to this crater, descended to the surface of the lake, and then into a _sub-crater_ in the midst of the larger. While he was busily engaged there in collecting specimens, a sudden bursting up of a huge volume of fluid lava from the bottom of the sub-crater, alarmed him, and threatened speedily to overwhelm and destroy him. He sprang to escape, but finding the rim overhanging, he could not scale it where he was; and the flowing mass was now too near to allow him to return to the place where he had descended; and its radiating heat was too intense to be faced. Escape without assistance was utterly hopeless; and the natives of the company who were about the brink, and from whom such help might have been expected, alarmed for themselves, were flying for their lives. Dr. Judd, giving himself up for lost, offered a prayer to heaven, and was about to resign himself to his fate, when a friendly and resolute Hawaiian, who had been a pupil at the mission seminary, compassionating the exposed sufferer, faced the approaching fiery volume, and braving its intense heat, exposed his own life, reached down his strong hand, and firmly grasped the doctor's, who thus, at the last available moment, through their united exertions and the blessing of heaven, escaped with his life from the horrible pit and a fiery grave! A mighty current instantly overflowed the place where they had just been standing, and they were obliged to run for their lives before the molten flood; and being able to outstrip it, they ascended from the surface of the abyss to the lofty rim, with heartfelt thanksgivings to their great deliverer.[1] This proves the real danger of descending too far into the crater of the volcano; and had it occurred in the days of unbroken superstition, it would doubtless have been ascribed to the anger of Pele, and tended to increase the number of her deluded worshipers. But now such a deliverance was justly ascribed to the kind providence of Jehovah, the knowledge of whose character, as displayed in the gospel, has introduced the Hawaiian race into a new life.

Footnote 1:

See United States Exploring Expedition, vol. iv., p. 173.

“Kilauea may be regarded as one of the safety-valves of a bottomless reservoir of melted earth, below the cooled and cooling crust on which mountains rise, rivers flow, oceans roll, and cities are multiplied as the habitations of men. It has been kept open from time immemorial, always displaying more or less of its active power. The circumambient air which carries off the caloric, sometimes aided by rain, is incessantly endeavoring to shut up this valve, or bridge over this orifice of three or four square miles of the fiery abyss. Sometimes the imperfect bridge of cooling lava is pierced with fifty or sixty large, rough, conical chimneys, emitting gas, smoke, flame, and lava; and sometimes the vast bridge is broken up, and all these cones submerged and probably fused again by the intense heat of the vast fluid mass supplied fresh from the interior. The mass rises gradually higher and higher, hundreds of feet, till by its immense pressure against the sides of the crater, aided, perhaps, by the power of gas or steam, it forces a passage for miles through the massive walls, and inundates with its fiery deluge some portion of the country below, or passing through it, as a river of fire, pours itself into the sea at the distance of twenty-five miles, thus disturbing with awful uproar the domains of old Neptune, and enlarging the dominions of the Hawaiian sovereign.

“The whole island, with its ample and towering mountains, is often shaken with awful throes, and creation here ‘groaneth and travaileth in pain.’ In July, 1840, a river of lava flowed out from Kilauea, and passing some miles under ground, burst out in the district of Puna, and inundated a portion of the country, sweeping down forests, carrying everything in its way before it, and as a river a mile wide, falling into the sea, and heating the waters of the ocean, making war upon its inhabitants, and by the united action of this volcanic flood and the sea, formed several huge, rough hills of sand and lava along the shore. And still later than the above date, a similar flood has been poured from the summit of Mauna Loa, flowing with terrific force for weeks, and thus elevating a portion of the region between Mauna Loa and Mauna Kea; and so extensive and splendid was this exhibition, that it could be seen from the missionary station at Hilo, a distance of about forty miles.

“After having spent some thirty hours on this king of all the volcanoes, we set out to return. And on our journey we passed over several large tracts of lava of different kinds, some smooth, vitreous and shining, some twisted and coiled like huge ropes, and some consisting of sharp, irregular, loose, rugged volcanic masses, of every form and size, from an ounce in weight to several tuns, thrown, I could not conceive how, into a chaos or field of the roughest surface, presenting a forbidding area of from one to forty square miles in extent; and though not precipitous, yet so horrid as to forbid a path, and to defy the approach of horses and cattle. In the crevices of the more solid lava are found the _ohelo_, which somewhat resembles the whortleberry, nourished by frequent showers and dew. At ten o’clock we halted for breakfast, and by the time the sun was setting had reached Waimea, thus completing our excursion to this vast volcano, which is truly _one of the wonders of the world_!”

THE PEAK OF DERBYSHIRE.

This peak consists of a chain of high mountains in the county of Derby, in England, and has been long celebrated, as well on account of its mineral productions, and natural curiosities in general, as of what are called its seven wonders. Six of these are natural, namely, Poole’s Hole, Elden Hole, the Peak Cavern, or the Devil’s Hole, Mam Tor, St. Ann’s Well, and the Ebbing and Flowing Well. Having described these, we shall add a more recent discovery, that of the Crystallized Cavern, which possesses an equal interest.

Poole’s Hole, lying about a mile to the westward of Buxton, is a vast cavern formed by nature in the limestone rock, and was, according to tradition, the residence of an outlaw, named Poole. The entrance is low and contracted, and the passage narrow; but this widening, at length, leads to a lofty and spacious cavern, from the roof of which stalactites or transparent crystals, formed by the constant dropping of water laden with calcareous matter, hang in spiral masses. Other portions of these petrifactions drop and attach themselves to the floor, rising in cones, and become what are termed stalagmites.

One of the dropping stalactites, of an immense size, called the Flitch of Bacon, occurs about the middle of the cavern, which here becomes very narrow, but soon spreads to a greater width, and continues large and lofty until the visitor reaches another surprisingly large mass of stalactite, to which the name of Mary Queen of Scots’ Pillar is given, from the tradition that this unfortunate queen once paid a visit to the cavern, and proceeded thus far into its recesses. As this pillar can not be passed without some difficulty, few persons venture beyond it; nor does it seem desirable, as, by proceeding thus far, a very competent idea of the

cavern may be formed. The path hitherto is along the side, and at some hight from the bottom of the cavern; but to visit and examine the interior extremity, it becomes necessary to descend a few yards by very slippery and ill-formed steps. The path at the bottom is tolerably even and level for about sixty feet, when an almost perpendicular ascent commences, which leads to the extremity of the fissure, through the eye of St. Anthony's Needle, a narrow strait, beyond which the steepness of the way is only to be surmounted by clambering over irregular masses of rock. The cavern terminates nearly three hundred feet beyond the Queen of Scots' pillar. Toward the end is an aperture through a projecting rock, behind which a candle is generally placed, when any person has reached the extremity: when seen at that distance, it appears like a dim star. The visitor returns along the bottom of the cavern, beneath a considerable portion of the road by which he entered; and, by thus changing the path, has an opportunity better to ascertain the hight and width of the cavern in every part, and to view other accumulated petrifactions, some of which are of a prodigious size, and of an extraordinary form. In one part of this passage is a fine spring of transparent water; and a small stream, which becomes more considerable in rainy seasons, runs through the whole length of the cavern. Its sound, in passing through this spacious and lofty concavity, which resembles the interior of a Gothic cathedral, has a fine effect. To the right, in a small cavern called Poole's chamber, is a curious echo.

The various masses of stalactical matter which are everywhere met with in this natural excavation, and which reflect innumerable rays from the lights carried by guides, are distinguished by the names of the objects they are fancied most to resemble. Thus we have Poole's saddle, his turtle, and his woolsack; the lion, the lady's toilet, the pillion, the bee-hive, &c. It should be noticed, however, that the forms are constantly varied by the percolation of the water through the roof and sides of the rock. The subterraneous passage is nearly a half a mile in length.

ELDEN HOLE.

Elden Hole is situated on the side of a gentle hill about a mile to the north-west of the village of Peak Forest. It is a deep chasm in the ground, surrounded by a wall, of uncemented stones, to prevent accidents. This fissure or cleft in the rock has been the subject of many exaggerated descriptions and superstitious reports, having been represented not only as unfathomable, but as teeming, at a certain depth, with so impure an air, that it could not be respired without immediate destruction. Mr. Lloyd, however, who descended it about seventy years ago, has proved the absurdity of these relations, in a paper, of which the following is a brief abstract, published in the Philosophical Transactions.

For the first sixty feet, he observes, he descended somewhat obliquely, the passage then becoming difficult from projecting crags. At the further depth of thirty feet, the inflection of his rope varied at least eighteen feet from the perpendicular. The breadth of the chink was here about nine feet, and the length eighteen; the sides being irregular, moss-grown, and wet. Within forty-two feet of the bottom, the rock opened on the east, and he swung till he reached the floor of a cave, one hundred and eighty-six feet only from the mouth, the light from which was sufficiently strong to permit the reading of any book. The interior of the chasm he describes as consisting of two parts, which communicate with each other by a small arched passage, the one resembling an oven, the other the dome of a glass-house. On the south side of the latter, was a small opening, about twelve feet in length, and four feet in hight, lined throughout with a kind of sparkling stalactite, of a fine deep yellow color, with petrifying drops hanging from the roof. Tracing the entrance he found a noble column, above ninety feet high, of the same kind of incrustation. As he proceeded to the north, he came to a large stone which was covered with the same substance; and beneath it he found a hole six feet in depth, uniformly lined with it. From the edge of this hole sprung up a rocky ascent, sloping, like a buttress, against the side of the cavern, and consisting of vast, solid, round masses of the same substance and color. Having climbed this ascent to the hight of about sixty feet, he obtained some fine pieces of stalactite, which hung from the craggy sides of the cavern. Descending with some difficulty and danger, he proceeded in the same direction, and soon came to another pile of incrustations of a brown color, above which he found a small cavern, opening into the side of the vault, which he now entered. Here he saw vast masses of stalactite, hanging like icicles from every part of the roof: several of these were four and five feet long, and thick as a man's body. The sides of the largest cavern were chiefly lined with incrustations of three kinds, the first of which was a deep yellow stalactite; the second, a thin coating which resembled a pale stone-color varnish, and reflected the light of the candle with great splendor; and the third, a rough efflorescence, the shoot of which resembled a rose flower.

Some more recent visitors have thus stated the result of their observations and inquiries relative to Elden Hole. They describe the mouth of this chasm as opening horizontally, in a direction from north to south; its shape being nearly that of an irregular ellipse, about ninety feet in length, and twenty-seven in breadth at the widest part. The northern end is fringed with small trees; and moss and underwood grow out of the crevices on each side, to the depth of forty or fifty feet. As the fissure recedes from the surface, it gradually contracts; and at the depth of about seventy feet inclines considerably to the west, so as to prevent its course from being

further traced. Notwithstanding the obstacles of the bushes and projecting masses of stone, it was sounded, and its depth found not to exceed two hundred and two feet, an estimate which corresponds with the assertion of three miners, who had descended in search of the bodies of individuals who were missing, and were supposed to have been robbed, murdered, and thrown into this frightful abyss.

PEAK CAVERN.

Peak cavern, also called the Devil's Hole, is one of those magnificent, sublime, and extraordinary productions of nature, which constantly excite the wonder and admiration of their beholders. It has accordingly been considered one of the principal wonders of Derbyshire, and has been celebrated by several poets. It lies in the vicinity of Castleton, and is approached by a path at the side of a clear rivulet, leading to the fissure, or separation of the rock, at the extremity of which the cavern is situated. It would be difficult to imagine a scene more august than that which presents itself to the visitor at its entrance: on each side, the huge gray rocks rise almost perpendicularly, to the hight of nearly three hundred feet, or about seven times the hight of a modern house, and meeting each other at right or cross angles, form a deep gloomy recess. In front, it is overhung by a vast canopy of rock, assuming the appearance of a depressed arch, and extending, in width, one hundred and twenty feet, in hight forty-two, and in receding depth about ninety. After penetrating about ninety feet into the cavern, the roof becomes lower, and a gentle descent leads, by a detached rock, to the interior entrance of this tremendous hollow. Here the light of day, having gradually diminished, wholly disappears; and the visitor is provided with a torch to illumine his further progress.

The progress now becoming extremely confined, he is obliged to proceed, in a stooping posture, about twenty yards, when he reaches a spacious opening, named the Bellhouse, and is thence led to a small lake, called the First Water, about forty feet in length, but not more than two or three feet in depth. Over this he is conveyed in a boat to the interior of the cavern, beneath a massive vault of rock, which in some parts descends to within eighteen or twenty inches of the water. "We stood some time," says M. de St. Fond, "on the brink of this lake; and the light of our dismal torches, which emitted a black smoke, reflecting our pale images from its bottom, we almost conceived we saw a troop of specters starting from an abyss to welcome us. The illusion was extremely striking."

On landing, the visitor enters a spacious vacuity, two hundred and twenty feet in length, two hundred feet in breadth, and in some parts one hundred and twenty feet in hight, opening into the bosom of the rock; but, from the want of light, neither the distant sides nor the roof of this abyss, can be seen. In a passage at the inner extremity of this vast cave, the stream which flows through the whole length of the cavern, spreads into what is called the Second Water, and near its termination is a projecting pile of rocks, known by the appellation of Roger Rain's House, from the incessant fall of water in large drops through the crevices of the roofs. Beyond this, opens another tremendous hollow, called the Chancel, where the rocks are much broken, and the sides covered with stalactical or petrified incrustations. Here the visitor is surprised by a vocal concert which bursts in discordant tones from the upper regions of the chasm. "Still," observes a tourist, "this being unexpected, and issuing from a quarter where no object can be seen, in a place where all else is still as death, is calculated to impress the imagination with solemn ideas, and can seldom be heard without that emotion of awe and pleasure, astonishment and delight, which is one of the most interesting feelings of the mind." At the conclusion of the strain, the choristers, who consist of eight or ten women and children, are seen ranged in the hollow of the rock, about fifty feet above the floor.

The path now leads to a place whimsically called the Devil's Cellar and Half-way House, and thence, by three natural and regular arches, to a vast concavity, which, from its uniform bell-like appearance, is called Great Tom of Lincoln. When illuminated by a strong light, this concavity has a very pleasing effect; the symmetrical disposition of the rocks, the stream flowing beneath, and the spiracles in the roof, forming a very interesting picture. From this point the vault gradually descends, the passage contracts, and at length does not leave more than sufficient room for the current of the stream, which continues to flow through a subterraneous channel of several miles in extent, as is proved by the small stones brought into it after great rains, from the distant mines of the Peak Forest.

The entire length of this wonderful cavern is twenty-two hundred and fifty feet, or nearly half a mile; and its depth, from the surface of the Peak mountain, about six hundred and twenty feet. A curious effect is produced by the explosion of a small quantity of gunpowder, wedged into the rock in the interior of the cavern; for the sound appears to roll along the roof and sides, like a tremendous and continued peal of thunder. The effect of the light, on returning from these dark recesses, is particularly impressive; and the gradual illumination of the rocks, which becomes brighter as the entrance is approached, is said to exhibit one of the most interesting scenes that ever employed the pencil of an artist, or fixed the admiration of a spectator.

MAM TOR.

Mam Tor or the Shivering Mountain, is a huge precipice facing the east or south-east, chiefly composed of a peculiar kind of slate, which, although very hard before it is exposed to the air, very easily crumbles to dust on such exposure. Hence it is perpetually wasted by the action of the rain and snow; while the harder and larger masses of stone being thus loosened and disengaged, necessarily fall from their positions, and this with a rushing noise which is occasionally so loud as to be heard at Castleton, a distance of two miles. The valley beneath is overwhelmed with their fragments to the extent of half a mile. In many parts of the precipice, they produce, before their descent, a cavernous appearance, and even a romantic overhanging scenery, highly dangerous to be approached. It is affirmed by the most intelligent of the neighboring inhabitants, that this mountain chiefly wastes during violent storms of snow and rain; and Mr. Martin, who published an account of Mam Tor, in the Philosophical Transactions for 1729, affirms that the decay is not constantly the same. He not only surveyed it closely, but ascended the steepest part of the precipice, without tracing any other shivering in the mountain, beside that which was occasioned by the treading of his feet in the loose crumbled earth.

THE EBBING AND FLOWING WELL.

In the vicinity of Chapel-en-le-Frith is a steep hill, rising to the hight of more than a hundred feet, immediately beneath which this natural phenomenon lies. It is of an irregular form, but nearly approaching to a square, from two or three feet in depth, and about twenty feet in width.

Its ebbings and flowings are irregular, and dependent on the quantity of rain which falls in the different seasons of the year; when it begins to rise, the current can only be perceived by the slow movement of the blades of grass, or other light bodies floating on the surface; notwithstanding which, before the expiration of a minute, the water issues with a gurgling noise, in considerable quantities, from several small apertures on the south and west sides. The interval of time between the ebbing and flowing is not always alike: consequently the proportion of water it discharges at different periods, also varies. In the space of five minutes flowing, the water occasionally rises to the hight of six inches; and, after remaining a few seconds stationary, the well assumes its former quiescent state.

The cause of the intermittent flowing of this well may be satisfactorily explained, on the principle of the action of the siphon, and on the supposition of a natural one communicating with a cavity in the hill, where the water may be supposed to accumulate; but for the phenomenon of its ebbing, no satisfactory reason has been assigned. The opinion of a second siphon, (which is ingeniously advanced by one tourist,) that begins to act when the water rises, is inconsistent with the appearance of the well, and therefore can not be just.

ST. ANNE'S WELL.

This well, the usual resort of the company who frequent Buxton to drink the waters, has been classed among the wonders of the peak, on account of this singularity, that within five feet of the hot spring by which it is supplied, a cold one arises. This is not, however, the only well of the kind, since hot and cold springs rise near each other in many parts of England, and in other countries. The water is conveyed to the well, which is an elegant classical building, in the Grecian style, from the original spring, by a narrow passage, so close and well contrived as to prevent it from losing any considerable portion of its heat, and is received in a white marble bason. It is not so warm as the Bath water, its temperature being about eighty degrees of Fahrenheit.

THE CRYSTALLIZED CAVERN.

The crystallized cavern, the new wonder of the Derbyshire Peak, was discovered some years ago in the vicinity of the village of Bradwell. We extract the following particulars of this singular and beautiful natural excavation, from Hutchinson's tour in the High Peak.

The entrance is rather terrific than grand; and the descent, for about thirty paces, very abrupt. The visitor has then to pass along the inclined way for nearly a quarter of a mile, the opening being so low that it is impossible to proceed, in particular parts, in an erect posture. The different crystallizations which now attract his attention on every side, soon make him forget the irksomeness of the road, and banish every idea of fatigue. New objects of curiosity crowd one on the other. In a place called the Music Chamber, the petrifactions take the semblance of the pipes of an organ; while in other parts, these stalactites are formed into elegant small colonnades, with as exact a symmetry as if they had been chiseled by the most skillful artist. Candles judiciously disposed within

them, give an idea of the imaginary palaces of fairies, or of sylphs and genii, who have chosen this for their magnificent abode.

Still he has seen nothing comparable to what he is now to expect; for, at the distance of about a hundred paces further, by a rugged descent, he enters what is called the Grotto of Paradise. This heavenly spot, for it can not be compared to anything terrestrial, is, of itself, a beautiful crystallized cavern, about twelve feet high, and in length twenty feet, pointed at the top, similar to a Gothic arch, with a countless number of large stalactites hanging from the roof. Candles placed among them give some idea of its being lighted up with elegant glass chandeliers; while the sides are entirely incrusted, and brilliant in the extreme. The floor is checkered with black and white spar. It has, altogether, a most novel and elegant appearance. This glittering apartment would be left by the visitor with a certain degree of regret, did he not expect to see it again on his return.

Still continuing a route similar to the one he has passed, in the course of which his attention is occasionally arrested by the curiosities of the place, and by the gentle droppings of the water, which scarcely break the solemn silence of the scene, he at length reaches the Grotto of Calypso, and the extremity of the cavern, upward of two thousand feet from the entrance. To see this grotto to advantage, he has to ascend about six feet, into a recess. There, the beautiful appearance of the different crystallizations, some of them of an azure cast, and the echoes reverberating from side to side, make him fancy he has reached the secluded retreat of some mythological deity.

Returning by the same path for a considerable distance, another cavern, which branches in a south-west direction from the one already explored, presents itself. The roads here are still more difficult of access, but the stalactites are certainly most beautiful. Many of them, more than a yard in length, are pendent from the roof, and the greater part do not exceed the dimension of the smallest reed. The top and sides of this cavern are remarkably smooth, particularly at the part called the Amphitheater. In general, the stone is of a very dark color, to which the transparent appearances before mentioned, with each a drop of water hanging at its extremity, form a fine contrast.

SPEEDWELL LEVEL.

In the Speedwell Level, or Navigation Mine, in the vicinity of Castleton, art has been combined with the subterraneous wonders of nature. Being provided with lights, the guide leads the visitor beneath an arched vault, by a flight of one hundred and six steps, to the sough or level, where a boat is ready for his reception, and is put in motion by pushing against pegs driven into the wall for that purpose. After proceeding about one-third of a mile through various caverns, the level bursts into a tremendous gulf, the roof and bottom of which are invisible, but across which the navigation has been carried, by throwing a strong arch over a part of the fissure where the rocks are least separated. Here, leaving the boat, and ascending a stage erected above the level, the attention of the visitor is directed to the dark recess of the abyss beneath his feet; and firm indeed must be his resolution, if he can contemplate the scene unmoved, and without an involuntary shudder. To the depth of ninety feet all is vacuity and gloom; but beyond that commences a pool of Stygian waters, not unaptly named the Bottomless Pit, the prodigious range of which may in some measure be conceived, by the circumstance of its having swallowed up more than forty thousand tuns of rubbish, made in blasting the rock, without any apparent diminution either of its depth or extent. The guides assert that the former has not been ascertained; but there is reason to believe that its actual depth in standing water is about three hundred and twenty feet. There can not, however, be a doubt but that this abyss has communications with others still more deeply situated in the bowels of the mountain, and into which the precipitated rubbish has found a passage. The superfluous water of the level falls through a water-gate into this profound caldron, with a noise like a rushing torrent.

This fissure is calculated to be about eight hundred feet beneath the surface of the mountain; and so great is its reach upward, that rockets of sufficient strength to ascend four hundred and fifty feet, have been fired without rendering the roof visible. The effect of a Bengal light discharged in this stupendous cavity, is extremely magnificent and interesting.

THE HIGH TOR.

This is one of the many sublime objects presented by Matlock dale, the beauties of which will be cursorily described, in proportion as these objects pass under our review.

In approaching the bath, which is nearly a mile to the south-west of the village of Matlock, a specimen of the scenery by which this charming vale is distinguished, presents itself. The entrance is through a rock, which has been blasted for the purpose of opening a convenient passage; and here a scene which blends the constituent principles of the picturesque, the beautiful and the sublime, opens suddenly on the view. Through the middle of a narrow plain flows the Derwent, overhung by a profusion of luxuriant beeches

and other drooping trees. Toward the east are gently rising grounds, and on the west the huge mural banks of the vale stretch along, the white face of the rock of which they are composed occasionally displaying itself through the woody clothing of their sides and summits. This magnificent scenery is singularly contrasted by the manufactories and lodging-houses at the bottom of the vale.

To see this magic spot to the greatest advantage, it should be entered at its northern extremity, its beauties then succeeding each other in a proper gradation, and their grandeur and effect being rendered more impressive. The chief attention is now attracted to the High Tor, a grand and stupendous rock, which appears like a vast abrupt wall of limestone, and rises almost perpendicularly from the river, to the hight of upward of three hundred and fifty feet. The lower part of this majestic feature is shaded by yew-trees, elms, limes, and underwood of various foliage; but the upper part, for fifty or sixty yards, presents a rugged front of one broad mass of perpendicular rock. From its summit the vale is seen in all its grandeur, diversified by woods of various hues and species. The windings of the Derwent, the grayish-colored rocks, and the white fronts of the houses, embosomed amid groves of trees which sprout from every crevice of the precipices, give variety and animation to a scene of wonderful beauty.

[Illustration: BRIDGE OVER THE WYE.]

CHEE TOR.

In a romantic and deep hollow, near the little village of Wormhill, the river Wye flows beneath this stupendous mass of rock, which rises perpendicularly more than three hundred and sixty feet above its level. The channel of the river, which meanders at the base, is confined between huge rocks of limestone, having such a general correspondence of situation and form, as to render it probable that they were once united. In some parts they are partially covered with brushwood, nut-trees and mountain-ash; while in others, they are totally naked, precipitous and impending. The chasm runs in a direction so nearly circular, that the sublime Chee Tor, and its dependent masses of rock, are almost insulated by the river which rolls at their feet. Its length, as far as it possesses any considerable beauty, is between five and six hundred yards; a distance which presents several picturesque and interesting views, the general effect of the fine scenery being enhanced by the plantations on the neighboring hights, and by a spring which flows into the river near the bottom of a deep descent, as well as by a romantic bridge over the river itself, a representation of which may be seen in the cut above. Not far from here is the well known Masson hill, celebrated in Darwin's "Loves of the Plants," which is so high as to overlook the country to a vast extent, and compared with which even the High Tor seems considerably diminished in grandeur and sublimity; but this effect is partly compensated by the extent of the prospect, and the variety of objects it comprehends. The hight of this eminence is about seven hundred and fifty feet, the path to its summit having been carried, in a winding direction, through a grove. About half-way in the ascent is an alcove, from which an extensive view of a great part of Matlock dale may be seen, through a fine avenue formed for that purpose.

THE CUMBERLAND CAVERN.

To the west and north-west of the village of Matlock, are three apertures in the rock, respectively named the Cumberland, Smedley, and Rutland caverns. The former of these is well deserving of a short notice.

The entrance is partly artificial, to afford a greater facility to the visitor, who has to descend fifty-four steps. The cavern now opens on him in solitary grandeur. Huge masses of stone are piled on each other with a tremendous kind of carelessness, evidently produced by some violent concussion, though at an unknown period. He is conducted to a long and wide passage, the roof of which has all the regularity of a finished ceiling, and is bespangled by spars of various descriptions. From above, from beneath, and from the sides, the rays of the lights are reflected in every direction. In an adjacent compartment, rocks are heaped on rocks in terrible array, and assume a threatening aspect. Next is an apartment decorated with what, in the language of the country, is called the snow-fossil, a petrifaction which, both in figure and color, resembles snow, as it is drifted by the winter storm into the cavities of a rock. Near the extremity of the cavern are to be seen fishes petrified and fixed in the several strata which form the surrounding recess. One of these has its back jutting out of the side of the earth, as if it had been petrified in the act of swimming. In another branch of the cavern a well has been found of a considerable depth.

REYNARD'S HOLE.

After having proceeded about a mile in Dove dale, the romantic and sublime beauties of which will be hereafter noticed, by a route constantly diversified by new fantastic forms, and uncouth combinations of rock, the visitor is led to a mass of mural rock, bearing the above name, and perforated by nature into a grand arch, nearly approaching to the shape of the sharply pointed Gothic style of architecture, about forty-five feet in hight, and in width twenty. Having passed through this arch, a steep ascent leads to a natural

cavern, called Reynard's Hall, forty-five feet in length, fifteen in breadth, and in hight thirty. From the mouth of this cavern the scenery is singular, beautiful and impressive. The face of the rock which contains the arch, rises immediately in front, and would effectually prevent the eye from ranging beyond its mighty barrier, did not its center open into the above-mentioned arch, through which is seen a small part of the opposite side of the dale, consisting of a mass of gloomy wood, from the shade of which a huge detached rock, solitary, cragged, and pointed, starts out to a great hight, and forms an object truly sublime. This rock, which has received the name of Dove Dale Church, is pleasingly contrasted by the little pastoral river, Dove, and by its verdant turfy banks. A narrow opening at the extremity of the cavern is supposed to lead to other similar cavities in the rock; and on the left is a cavern, about forty feet in length, in breadth fourteen, and in hight twenty-six, called Reynard's Kitchen, from the interior of which a pleasing view is presented of the upper part of the dale, its river and rocks.

After passing Reynard's Hole, already described, the rocks rise more abruptly on either side, and appear in shapes more wild and irregular, but diversified and softened by shrubs.

Dove dale is nearly three miles in length; but from the sinuosity of its course, and its projecting precipices, the views are limited. Throughout the whole of this majestic feature of country, the river Dove flows, in the halcyon days of summer, with soft murmurs, innocently and transparently over its pebbly bed; but swells into rage during the winter months. Little tufts of shrubs and underwood form islands in miniature within its bed, which enlarge and swell the other objects. The scenery of this dale is distinguished from almost every other in the united kingdoms, by the rugged, dissimilar, and frequently grotesque and fanciful appearance of the rocks. To employ the words of a tourist here, "It is, perhaps, on the whole one of the most pleasing sceneries of the kind anywhere to be met with. It has something peculiarly characteristic. Its detached, perpendicular rocks stamp it with an image entirely its own, and for that reason it affords the greater pleasure. For it is in scenery as in life. We are most struck with the peculiarity of an original character, provided there be nothing offensive

THOR'S HOUSE.

"Where Hamps and Manifold, their cliffs among, Each in his flinty channel winds along, With lucid lines the dusky moor divides, Hurrying to intermix their sister tides, Where still their silver-bosom'd nymphs abhor The blood-smear'd mansion of gigantic Thor— Erst fires volcanic in the marble womb Of cloud-wrapp'd Whetton rais'd the massy dome; Rocks rear'd on rocks, in huge disjointed piles, Form the tall turrets, and the lengthen'd aisles; Broad pond'rous piers sustain the roof, and wide Branch the vast rainbow ribs from side to side. While from above, descends, in milky streams, One scanty pencil of illusive beams, Suspended crags, and gaping gulfs illumes, And gilds the horrors of the deepen'd glooms. Here oft the Naiads, as they chanc'd to stray Near the dread Fane, on Thor's returning day, Saw from red altars streams of guiltless blood, Stain their green reed-beds, and pollute their flood; Heard dying babes in wicker prisons wail, And shrieks of matrons thrill the affrighted gale; While from dark caves infernal echoes mock, And fiends triumphant shout from every rock!"—DARWIN.

This spacious cavern is situated about two miles above Dove dale, near the village of Whetton; and tradition says the Druids here offered human sacrifices, inclosed in wicker idols, to Thor, the principal deity of the Saxons and Danes, in the ages of their idolatrous worship. Beneath is an extensive and romantic common, where the rivers Hamps and Manifold sink into the earth, and rise again in Islam gardens. These rivers merit a brief description. A wooden bridge has been thrown over an abyss in the rock, out of which the river Manifold bursts with surprising force, after having pursued a subterraneous course of five miles, from the point where it had engulfed itself in the earth, called Weston hill. At the further distance of twenty yards a similar phenomenon occurs; for here another fissure of a rock presents itself, whence the river Hamps throws its water into day. This river disappears at Leek-water Houses, a place between Leek and Ashbourn; thus pursuing a subterraneous course of seven miles, before it again emerges into light. On their emersion, the temperatures of the two rivers differ two degrees and a half, the Hamps being the coldest.

THE LOVERS' LEAP.

The environs of Buxton abound in romantic sites, among the most striking of which is the dale named the Lovers' Leap, on account of a vast precipice which forms one side of a narrow chasm, and from the summit of which a love-lorn female is said to have precipitated herself into the rocky gulf below. Each side of this beautiful dell is bounded by elevated rocks, the proximity of which is such, that for a considerable space there is scarcely room for the passage of the bubbling current of the Wye. Several of these rocks are perpendicular, and bare of vegetation; while others are covered with ivy, yew and ash-wood, with a craggy steep occasionally starting through the verdure. A circular road, extending in circumference about three miles, passes in view of the most romantic part of this dale, and forms a very agreeable walk or ride from Buxton. At the southern extremity the scenery assumes a

milder character, the hollow taking the name of Mill dale, from a mill which is turned by the stream. In conjunction with a rude bridge, a mountainous path, and other rural objects, this forms a very picturesque view. Another fine scene is presented by a lofty rock, called Swallow Tor, which soars over a mass of wood, the river at its base foaming and roaring over broken masses of limestone.

THE MOORS.

Derbyshire is everywhere fruitful in natural curiosities, among the most striking of which may be reckoned the moors of Hope parish, inasmuch as they afford an extraordinary instance of the preservation of human bodies interred in them. In the year 1674, a grazier and his female servant, in crossing these moors on their way to Ireland, were lost in the snow, with which they were covered from January to May, and being then discovered, the bodies were so offensive that the coroner ordered them to be buried on the spot. After a lapse of twenty-nine years, when the ground was opened, they were in no way changed, the color of the skin being fair and natural, and the flesh as soft as that of persons newly dead. For twenty succeeding years they were occasionally exposed as a spectacle, but carefully covered after being viewed. They lay at the depth of about three feet, in a moist soil or moss. The minister of Hope parish was present in 1716, forty-two years after the accident, at a particular inspection of these bodies. On the stockings being drawn off, the man's legs, which had not been uncovered before, were quite fair: the flesh, when pressed by the finger, pitted a little; and the joints played freely, without the least stiffness. Such parts of the clothing as the avidity of the country people, to possess so great a curiosity, had spared, were firm and good; and a piece of new serge, worn by the woman, did not appear to have undergone any sensible change.

OTHER ENGLISH CURIOSITIES.

Having thus brought to a conclusion our details relative to the wonders of the peak, and the various and interesting natural curiosities there to be found, we subjoin a brief notice of several others, which have, in England, attracted the notice of travelers.

Among the extraordinary caverns to be found in the mountains of the north of England, may be reckoned Yordas cave, in the vale of Kingsland, in Yorkshire, which contains a subterraneous cascade. Whethercot cave, not far from Ingleton, is divided by an arch of limestones, passing under which is seen a large cascade falling from a hight of more than sixty feet. The length of this cave is about one hundred and eighty feet, and the breadth ninety.

There are also in various parts of England many remarkable springs, of which some are impregnated either with salt, (as that of Droitwich, in Worcestershire,) or sulphur, (as the famous well of Wigan, in Lancashire,) or bituminous matter, (as that at Pitchford, in Shropshire.) Others have a petrifying quality, as that near Lutterworth, in Leicestershire, and a dropping well in the West Riding of Yorkshire. And, finally, some ebb and flow, as that of the peak described above, and Laywell near Torbay, whose waters rise and fall several times in an hour. To these we may add that remarkable fountain near Richard's Castle, in Herefordshire, commonly called Bone Well, which is generally full of small bones, like those of frogs or fishes, though often cleared out. At a cliff near Wigan, in Lancashire, is the famous burning well: the water is cold, neither has it any smell; yet so strong a vapor of sulphur issues out with the stream, that upon applying a light to it, the top of the water is covered with a flame, like that of burning spirits, which lasts several hours, and emits such a heat that meat may be boiled over it.

MOUNTAINS OF GREAT BRITAIN.

The British isles present many mountains of a bold and imposing character: when contrasted, however, with those which have been already described, they must be considered as comparatively diminutive.

BEN NEVIS.

The loftiest of these mountains is Ben Nevis, in Scotland, its elevation above the level of the sea being forty-three hundred and eighty feet, or somewhat more than four-fifths of a mile. It terminates in a point, and elevates its rugged front far above all the neighboring mountains. It is of easy ascent; and at the perpendicular hight of fifteen hundred feet, the vale beneath presents a very agreeable prospect, the vista being beautified by a diversity of bushes, shrubs, and birch woods, besides many little verdant spots. The sea and the shore are also seen.

At the summit, the view extends at once across the island, eastward toward the German sea, and westward to the Atlantic ocean. Nature here appears on a majestic scale and the vastness of the prospect engages the whole attention, at the same time the objects in view are of no common dimensions. Just over the opening of the sound, at the south-west corner of Mull, Colonsay rises

out of the sea like a shade of mist, at the distance of more than ninety miles. Shuna and Lismore appear like small spots of rich verdure, and, though nearly thirty miles distant, seem quite under the spectator. The low parts of Jura can not be discerned, nor any part of Isla; far less the coast of Ireland, as has been asserted. Such is, however, the wide extent of view, that it extends one hundred and seventy miles from the horizon of the sea at the Murray frith, on the north-east, to the island of Colonsay, on the south-west.

On the north-east side of Ben Nevis is an almost perpendicular precipice, certainly not less than fourteen hundred feet in depth; probably more, as it appears to exceed the third part of the entire hight of the mountain. A stranger is astonished at the sight of this dreadful rock, which has a quantity of snow lodged in its bosom throughout the whole year. The sound of a stone thrown over the cliff to the bottom, can not be heard when it falls, so that it is impossible to ascertain in that way the hight of the precipice.

SNOWDON.

This is the loftiest of the Welch mountains, its elevation above the level of the sea being thirty-seven hundred and twenty feet, or nearly three-quarters of a mile. It is accessible on one side only, its flanks being in every other quarter precipitous. Its aspect soon convinces the spectator that he is not to look to the Alps alone, or to the rocky regions of Altai, bordering on Siberia, for romantic scenes of wildness, confusion and disorder. Snowdon presents them in all their rude and native majesty.

In the ascent, a narrow path not more than nine feet in width, leads along the margin of a frightful precipice of nearly fifteen hundred feet in extent, so perpendicular that it can not be approached without terror; while to the north of the summit nearest to the one the most elevated, a semi-amphitheater of precipitous rocks, also of a great hight, is seen; and, behind this summit, another semicircle of equal depth and extent. The loftiest summit here appears to descend in the form of a sharp ridge, and beneath it another appears, which, on account of its color, is called the Black Rock. From the upper part of the valley, one of these summits presents a grand, vertical, and very elevated point.

The bottom of each of the amphitheaters of rocks, thirteen in number, is occupied by a small lake of a circular form, and very deep. The one known by the name of Llyn Glass is remarkable for its green hue, derived from its being impregnated with copper, several mines of which line its borders. Than this mountain, nothing in the Alps can be more arid and desert, those regions alone excepted which are too lofty to admit of vegetation. Here there is not a tree, not even a shrub; small patches of verdure, which sheep can scarcely reach, are alone to be seen. Its summit, or highest peak, is a flat of about eighteen feet only in circumference. Thence may be seen a part of Ireland, a part of Scotland, Cumberland, Lancashire, Cheshire, all North Wales, the isle of Man, and the Irish and British seas, with innumerable lakes; while the whole island of Anglesea is displayed so distinctly, that, its flat uncultivated plains, bounded by the rich Parys mountain in the vicinity of Holyhead, may be descried as on a map.

CADER IDRIS.

To the south of Dolgellau, Cader Idris towers above the subject mountains, which seem to retire, to allow its base more room to stand, and to afford to their sovereign a better display. It stands on a broad rocky base, with a gradual ascent to its brow, when the peaks elevate themselves in a manner at once abrupt, picturesque and distinct. The point emphatically named Cader, appears to the eye below to be little superior in hight to the saddle; but the third point, or apex, which has a name expressive of its sterility, is neither equal in hight, nor in beauty, to the other two. On its loftiest peak a stone pillar has lately been erected, for the purpose of a trigonometrical survey.

Cader Idris is the commencement of a chain of primitive mountains, and is computed to be twenty-eight hundred and fifty feet above the green of Dolgellau, and thirty-five hundred and fifty feet, or nearly three-fourths of a mile above the level of the sea. It has been conjectured that at some remote period it was a volcano of immense magnitude.

The tract to the south of Cader Idris, as far as Talylyn and Malwydd, is peculiarly grand. High and rugged mountains of every possible form, close in on all sides, while huge masses of rock hang over, or lie scattered in misshapen fragments by the side of the road. To add to the effect of this scene, the river Difi forms one continued cataract for five or six miles, overflowing with the innumerable tributary torrents which precipitate themselves from the highest summits of the surrounding rocks; while, to crown the whole, the shady head of Cader Idris towers, the majestic sentinel of the group.

PENMAN-MAWR.

The county of Caernarvon, in which this mountain is situated, claims precedency over every other in Wales, for the loftiness of its mountains, and the multitude of the eminences, which in a curved and indented chain, occupy nearly the whole of its extent.

In proceeding from Conway to Bangor, by a route at once picturesque and romantic, and amid a scenery which varies at every step, Penman-mawr discloses to the traveler its bulky head. It protrudes itself into the sea, and exhibits a fine contrast to the fertility which it interrupts, by a rude view of gray weather-beaten stones and precipices. The passage over the mountain was formerly terrific; but the road has been latterly widened and secured, near the verge of the precipice, by a small wall about five feet in hight. It forms the most sublime terrace in the British isles, winding round the mountain on the edge of the abrupt cliff; while the vast impending rocks above, the roaring of the waves at a great distance below, and the frequent howling of the wind, all unite to fill the mind with solemnity and awe.

SKIDDAW.

This English mountain, which has an elevation of thirty-five hundred and thirty feet, or nearly three-fourths of a mile above the level of the sea, is situated in Cumberland. It is more remarkable on account of the scenery over which it presides, and which exceeds in beauty whatever the imagination can paint, than for those bold projections and that rugged majesty which might be expected, but which will be here sought in vain. Except at such a distance as smooths the embossed work of all these rich fabrics, and where its double summit makes it a distinguished object to mark and characterize a scene, it may be considered as a tame and inanimate object.

WHARNSIDE.

In some of the maps of Yorkshire, the hight of this mountain is greatly exaggerated, its elevation above the sea not being more than twenty-five hundred feet, or nearly half a mile. As it is situated in the midst of a vast amphitheater of hills, the prospect it affords is diversified with pleasing objects. On its summit are four or five small lakes, two of which are about nine hundred feet in length, and nearly the same in breadth. A thin seam of coal also occurs near the top, and another is said to correspond with it on the summit of the lofty Colm hill, on the opposite side of Dent dale. Numerous caves and other natural curiosities abound here, as well as on Pennigent, about six miles to the eastward of Ingleborough. These latter mountains do not possess any particular interest.

STROMBOLI.

Stromboli is the principal of the cluster of small islands, lying to the north of Sicily, named the Lipari isles, the whole of which contain volcanoes. At a distance, its form appears to be that of an exact cone, but on a closer examination it is found to be a mountain having two summits of different hights, the sides of which have been torn and shattered by craters. The most elevated summit, inclining to the south-west, is, agreeably to Spallanzani, about a mile in hight.

In this volcanic mountain, the effects of a constantly active fire are everywhere visible, heaping up, destroying, changing, and overturning every instant what itself has produced, and incessantly varying in its operations. At the distance of one hundred miles, the flames it emits are visible, whence it has been aptly denominated the light-house of that part of the Mediterranean sea.

From the more elevated summit, all the inner part of the burning crater, and the mode of its eruption, may be seen. It is placed about half-way up, on the north-west side of the mountain, and has a diameter not exceeding two hundred and fifty feet. Burning stones are thrown up at regular intervals of seven or eight minutes, ascending in somewhat diverging rays. While a portion of them roll down toward the sea, the greater part fall back into the crater; and these being again cast out by a subsequent eruption, are thus tossed about until they are broken and reduced to ashes. The volcano, however, constantly supplies others, and seems inexhaustible in this species of productions. Spallanzani affirms that, in the more violent eruptions, the ejected matter rises to the hight of half a mile, or even higher, many of the ignited stones being thrown above the highest summit of the mountain.

The erupted stones, which appear black in the day-time, have at night a deep red color, and sparkle like fire-works. Each explosion is accompanied by flames or smoke, the latter resembling clouds, in the lower part black, in the upper white and shining, and separating into globular and irregular forms. In particularly high winds from the south or south-east, the smoke spreads over every part of the island. Spallanzani observed this volcano on a particular night, when the latter of these winds blew with great violence. The clear sky exhibited the appearance of a beautiful aurora borealis over that part of the mountain on which the volcano is situated, and which from time to time became more red and brilliant, in proportion as the ignited stones were thrown to a greater hight. The violence of the convulsions depends on that of the wind.

The present crater has burned for more than a century, without any apparent change having taken place in its situation. The side from which the showers of ignited matter fall into the sea, is almost perpendicular, about half a mile broad at the bottom, and a mile in length, terminating above in a point. In rolling down, the lava raises the fine sand like a cloud of dust. While this was observed by Spallanzani, the volcano suddenly made an eruption. Numerous pieces of lava of a dark red color, and enveloped in smoke, were ejected from the top of the precipice, and thrown high into the air. A part of them fell on the declivity, and rolled down, the smaller preceded by the greater; after a few bounds, dashing into the sea, giving out a sharp hissing sound. The more minute fragments, from their lightness, and the hindrance of the sand, rolled slowly down, and striking against each other, produced nearly the same sound as hail-stones falling on a roof. In a few minutes another explosion followed, without any sensible noise; and two minutes after a third eruption took place, with a much louder explosion than the first, and a far more copious ejection of lava. The eruptions, which were almost innumerable during the time Spallanzani remained there, all exhibited the same appearances.

On the night following the one above described, the volcano raged with still greater violence, and rapidly hurled to a great hight, thousands of red-hot stones, forming diverging rays in the air. Those which rolled down the precipice, produced a hail of streaming fire, which illuminated the steep descent. Independently of these ignited stones, there was in the air which hovered over the volcano, a vivid light, which was not extinguished when that was at rest. It was not properly flame, but real light reverberated by the atmosphere, impregnated by extraneous particles, and more especially by the ascending smoke. Besides varying in intensity, it appeared constantly in motion, ascending, descending, dilating and contracting, but always remaining perpendicular over the mouth of the volcano, which showed that it was occasioned by the conflagration within the crater. The detonations in the greater eruptions resembled the roaring of distant thunder, and in the lesser ones, the explosions of a mine. In the smallest they were scarcely audible. Each was some seconds later than the ejection.

Near the mouth of the volcano is a small cavern, a projection above which secures it from the entrance of the ignited stones. From this cavern Spallanzani was enabled to look down into the very bowels of the volcano. He describes the edges of the crater as of a circular form, and not more than three hundred and forty feet in circumference, the internal sides contracting as they descend, and assuming the shape of a truncated inverted cone. The crater itself, to a certain hight, is filled with a liquid red-hot matter, resembling melted brass. This is the fluid lava, which appears to be agitated by two distinct motions, the one intestine, whirling and tumultuous, and the other that by which it is impelled upward. This liquid matter is raised, sometimes with more, and sometimes with less rapidity, within the crater; and when it has reached within twenty-five or thirty feet of the upper edge, a sound is heard not unlike a short clap of thunder, while at the same moment a portion of the lava, separated into a thousand pieces, is thrown up with indescribable swiftness, accompanied by a copious eruption of smoke, ashes and sand. A few moments before the report, the superficies of the lava is inflated and covered with large bubbles, some of which are several feet in diameter; on the bursting of these the detonation and fiery shower take place. After the explosion, the lava within the crater sinks, but soon rises again as before, and new bubbles appear, which again burst and produce new explosions. When the lava sinks, it gives little or no sound; but when it rises, and particularly when it begins to be inflated with bubbles, it is accompanied by a noise similar, in proportion to the difference of magnitude, to that of liquor boiling vehemently in a caldron.

LIPARI.

This island, which has given name to the whole cluster, is deserving of notice on account of its celebrated “_stoves_.” They are the only vestiges of subterraneous conflagration now remaining, and lie to the west of the city, on the summit of a mountain of considerable elevation, called Monte della Stufe, the Mountain of Stoves. They consist of five excavations, in the form of grottos; but two of them have been abandoned on account of the great heat, an exposure to which might cause suffocation. Even the stones are so hot that they can not be touched; but still the heat varies, and experiences all the vicissitudes of volcanoes. The ground is not penetrated with hot vapors issuing from several apertures, as has been asserted. Spallanzani, however, found one from which a thin stream of smoke issued from time to time, with a strong sulphureous smell, indicating the remains of conflagration existing beneath.

It is impossible to fix the exact epoch at which the fires of Lipari were extinguished, or rather the period at which the eruptions ceased, for the existence of the former may be deduced from the hot springs and stoves. Dolomieu thinks the last eruptions are as old as the sixth century of the Christian era, and conjectures that they may have ceased since the fires found a new vent in Vulcano, since he does not entertain any doubt but that the two islands have a subterraneous communication. Of this the inhabitants of Lipari are so well convinced, that they are in the greatest agitation when Vulcano does not smoke, and when its passages are obstructed. They fear shocks and violent eruptions, suspecting even that the fires may again break out in their island.

It is a fact that the earthquakes, which are very frequent, generally cease when the eruptions of Vulcano commence.

VULCANO.

This, which is the last of the Lipari isles, bears in every part the stamp of fire. It was the superstitious belief of the ancient inhabitants that Vulcan had here established his forges, there being constant fires during the night, and a thick smoke throughout the day. It consists of a mountain in the form of a truncated cone, which is, however, merely a case opening and exposing to view a second cone within, more exact than the other, and in which the mouth of the volcano is placed. The latter is thus enveloped on three sides by the ancient cone, and is open only on that side which is immediately washed by the sea.

The base of the interior cone is separated from the steep sides of the ancient crater by a circular valley, which terminates on one side at the junction of the two mountains, and on the other sinks into the sea. In this valley, light pumice-stones are blended with fragments of black, vitreous lava, and buried in ashes perfectly white. The blow of a hammer on these stones produces a loud hollow sound, which reëchoes in the neighboring caverns, and proves that the surface is nothing more than the arch of a vault covering an immense abyss. The sound varies according to the thickness of the crust, which must have considerable solidity to support the weight of the new mountain. This, according to Dolomieu, is higher and steeper than the cone which contains the crater of Etna, and its access still more difficult; its perpendicular hight, however, is not more than twenty-six hundred and forty feet, or half a mile. He represents the crater of Vulcano as the most magnificent he ever saw; and Spallanzani observes that, with the exception of that of Etna, he does not know of any more capacious and majestic. It exceeds a mile in circuit, has an oval mouth, and its greatest diameter is from the south-east to the west, while its depth is not more than a quarter of a mile. The bottom is flat, and from many places streams of smoke exhale, emitting a strong sulphureous vapor. This vast cavity is very regular, and as its entire contents are displayed to the eye, presents one of the grandest and most imposing spectacles in nature. On large stones being rolled down, the mountain reëchoes; and on their reaching the bottom, they appear to sink in fluid. Indeed, with the aid of a glass, two small lakes, supposed to be filled with melted sulphur, have been discovered. The declivity of the interior walls is so great, that, even when there is not any danger from fire, the descent is next to impossible. After considerable difficulty, however, this was accomplished by Spallanzani on the south-east side, the only one accessible. He found the bottom to be somewhat more than one-third of a mile in circumference, and of an oval form. The subterraneous noise was here much louder than on the summit, sounding like an impetuous river foaming beneath, or, rather, like a conflict of agitated waves meeting and clashing furiously together. The ground was likewise in some places perforated with apertures, from which hissing sounds issued, resembling those produced by the bellows of a furnace. It shook when pressed by the feet; and a large piece of lava, let fall five or six feet, produced a subterraneous echoing sound, which continued some time, and was loudest in the center. These circumstances, combined with its burning heat, and the strong stench of sulphur it emits, prove that the fires of the volcano are still active.

Its eruptions have been most considerable during the earthquakes which have desolated Sicily and a greater part of Italy. In the month of March, 1786, after subterraneous thunders and roarings, which were heard over all the islands, to the great terror of the inhabitants, and were accompanied by frequent concussions, the crater threw out a prodigious quantity of sand, mixed with immense volumes of smoke and fire. This eruption continued fifteen days, and so great was the quantity of sand ejected that the circumjacent places were entirely covered with it to a considerable hight. The lava did not flow at the time, at least over the edges of the crater; and indeed, such a current is not remembered by any living person.

THE HIMALAYA MOUNTAINS. BETWEEN INDIA AND THIBET.

“The great Himalayan snowy range,” says Mr. Fraser, “is only the high elevated crest of the mountainous tract that divides the plains of Hindoostan from those of Thibet, or Lesser Tartary. Far as they predominate over, and precipitously as they rear themselves above the rest, all the hills that appear in distant ranges, when viewed from the plains, are indeed only the roots and branches of this great stem; and, however difficult to trace, the connection can always be detected between each inferior mountain and some particular member of its great origin.

“The horizontal depth of this mountainous tract, on that side which overlooks Hindoostan, is no doubt various; but, from the difficulty of the country, a traveler performs a journey of many days before he reaches the foot of the immediate snowy cliffs. The best observations and surveys do not authorize the allowance of more than an average depth of about sixty miles from the plains to the commencement of these, in that part of the country that forms the subject of this narrative. The breadth of the snowy zone itself in all probability varies still more; for huge masses advance in some places into the lower districts, and in others the crest recedes in long ravines, that are the beds of torrents, while behind they are clothed by a succession of the loftier cliffs. Every account we

receive of a passage through them, (and this is no doubt found most commonly where the belt is narrowest,) gives a detail of many days' journey through the deserts of snow and rocks; and it is to be inferred, that on the north-east side they advance to, and retreat from the low ground in an equally irregular manner. Indeed, some accounts would induce the belief, that long ranges, crowned with snow-clad peaks, project in various places from the great spine, and include habitable and milder districts; for, in all the routes of which we have accounts, that proceed, in various directions toward the Trans-Himalayan countries, hills covered with snow are occasionally mentioned as occurring, even after the great deserts are passed, and the grazing country entered. The breadth, then, of this crest of snow-clad rock itself, can not fairly be estimated at less than from seventy to eighty miles.

"The great snowy belt, although its loftiest crest is broken into numberless cliffs and ravines, nevertheless presents a barrier perfectly impracticable, except in those places where hollows that become the beds of rivers have in some degree intersected it, and facilitated approach to its more remote recesses, or courageous and attentive perseverance has here and there, discovered a dangerous and difficult path, by which a possibility exists of penetrating across the range. Few rivers hold their course wholly through it: indeed, in the upper part the Sutlej alone has been traced beyond this rocky barrier; and there is a path along its stream, from different parts of which roads diverge, that lead in various directions through the mountain. No reasonable doubt can now exist of the very long and extraordinary course which this river takes.

"Captain Webb of the Bengal establishment, was at one time employed on a survey of a province of Kumaoon. On the twenty-first day of June, his camp was eleven thousand, six hundred and eighty feet above Calcutta. The surface was covered with very rich vegetation as high as the knee; there were very extensive beds of strawberries in full flower; and plenty of currant-bushes in blossom all around, in a clear spot of rich black mold soil, surrounded by a noble forest of pine, oak and rhododendron. On the twenty-second of June he reached the top of Pilgoenta-Churhaee, (or ascent,) twelve thousand, six hundred and forty-two feet above Calcutta. He was prevented from distinguishing very distant objects by a dense fog; but there was not the smallest patch of snow near him; and the surface, a fat black mold through which the rock peeped, was covered with strawberry plants, (not yet in flower,) butter-cups, dandelions, and a profusion of other flowers. The shoulders of the hill above him, about four hundred and fifty feet more elevated, were covered with the same to the top; and above five hundred feet below was a forest of pine, rhododendron and birch. There was some snow seen below in deep hollows, but it dissolves in the course of the season. These facts led Captain Webb to infer, that the inferior limit of perpetual congelation on the Himalaya mountains is beyond thirteen thousand, five hundred feet, at least, above the level of Calcutta: and that the level of the table-land of Tartary, immediately bordering on their range, is very far elevated beyond eight thousand feet, the hight at which it has been estimated.

"On the night of the sixteenth of July, we slept at Bheemkeudar, near the source of the Coonoo and Bheem streams. There is no wood near this place, even in the very bottom of the valley, and we had left even the stunted birch at a considerable distance below; but there was a profusion of flowers, ferns, thistles, &c., and luxuriant pasturage. Captain Webb's limit of wood is at least as high as twelve thousand to twelve thousand, three hundred feet. I would, therefore, presume the site of Bheemkeudar to be considerably above that level; say thirteen thousand to thirteen thousand, three hundred feet, above the level of Calcutta. From thence we ascended at first rather gradually, and then very rapidly, till we left all luxuriant vegetation, and entered the region of stripped and scattered and partially melting snow. From calculating the distance passed, and adverting to the elevation we had attained, I would presume that this was at least fifteen hundred feet above Bheemkeudar, or from fourteen thousand, five hundred, to fifteen thousand feet above Calcutta.

"We proceeded onward, ascending very rapidly, while vegetation decreased gradually to a mere green moss, with here and there a few snow-flowers starting through it; snow fast increasing, till at length we entered on what I presume was the perennial and unmelting snow, entirely beyond the line of vegetation, where the rock was bare even of lichens: and in this we ascended, as I think, about eight hundred feet; for, though Bamsooroo Ghat may not be so far above this line, we continued ascending, even after crossing that point, and I would incline to estimate this utmost extent of ascent at two thousand feet more, or nearly seventeen thousand feet above the level of Calcutta.

"Whilst proposing to consider the point of sixteen thousand to sixteen thousand, five hundred feet, as that of inferior congelation, I must observe that there was no feeling of _frost_ in the air, and the snow was moist, though hard, chiefly through the influence of a thick mist, which, in fact, amounted to a very small drizzling rain, which fell around: all which would seem to indicate, that the true line of congelation had not there been attained; but we were surrounded by snow which evidently never melted. To a great depth below it extended all over the hills, very little broken, while on the valleys from whence the Coonoo and Bheem streams issue, at full two thousand feet below, it lay covering them and the surrounding mountains in an unbroken mass, many hundred feet thick. Thus, though it may seem contradictory, the line of perpetual congelation, in fact seems fixable at even below the point I have

ventured to indicate, and, I presume, might, on these grounds, be placed somewhere between fifteen and sixteen thousand feet above the level of Calcutta.

“The result of all the considerations that arise out of the foregoing remarks is a belief, that the loftiest peaks of the Himalaya range will be found to fall considerably short of the hight attributed to them by Mr. Colebrooke; and that their loftiest peaks do not more than range from eighteen thousand to twenty-two or twenty-three thousand feet above the level of the sea.

“Having reached the top of an ascent, we looked down upon a very deep and dark glen, called Palia Gadh, which is the outlet to the waters of one of the most terrific and gloomy valleys I have ever seen. But it would not be easy to convey by any description a just idea of the peculiarly rugged and gloomy wildness of this glen: it looks like the ruins of nature, and appears, as it is said to be, completely impracticable and impenetrable. Little is to be seen except dark rock: wood only fringes the lower parts and the waters’ edge: perhaps the spots and streaks of snow, contrasting with the general blackness of the scene, highten the appearance of desolation. No living thing is seen; no motion is visible but that of the waters; no sound is heard but their roar. Such a spot is suited to engender superstition, and here it is accordingly found in full growth. Many wild traditions are preserved, and many extravagant stories related of it.

“The glen above described, is by far the most gloomy, savage scene we have yet met with. I regret that the weather did not permit a sketch of it to be attempted. Beyond this we could see nothing in the course of the river but rocky banks. The opposite side is particularly precipitous; yet along its face a road is carried, which is frequented as much as this, and leads to villages still farther up. By the time we had reached the village, the clouds which had lowered around and sunk down on the hills, began to burst with loud thunder and heavy rain. The noise was fearfully reverberated among the hills; and during the night more than once the sound was heard of fragments from the brows of the mountains, crashing down to the depths below with a terrific din. Our quarters were good. I slept in a temple, neat, clean and secure from the weather.”

[Illustration: SOURCE OF THE JUMNA.]

GUNGOTREE, THE SOURCE OF THE JUMNA, A BRANCH OF THE GANGES, IN THE HIMALAYA MOUNTAINS.

Gungotree, the source of the Jumna, represented in the cut below, the most sacred branch of the Ganges, ought to hold, and does hold the first rank among its holy places. Here all is mythological ground. Here Mahadeo sits enthroned in clouds and mist, amid rocks that defy the approach of living thing, and snows that make desolation more awful. Gods, goddesses and saints here continually adore him at mysterious distance, and you traverse their familiar haunts. But, although Gungotree be the most sacred, it is not the most frequented shrine, access to it being far more difficult than to Buddrinauth; and consequently to this latter, pilgrims flock in crowds, appalled at the remoteness and danger of the former place of worship. This may pretty fully account for the superior riches and splendor of Buddrinauth. Here are temples of considerable extent, priests and officials in abundance, who preserve an imposing exterior, and an appearance venerable from power and comparative magnificence, and consequently procure rich and ample offerings to keep up their comfortable dignity.

The temple of Bhadrinath, is situated on the west bank of the Alackunda, in a valley four miles long, and one mile in its greatest breadth. The east bank rises considerably higher than the west bank, and is on a level with the top of the temple. The position of the sanctuary is considered equidistant from two lofty mountains, which are designated by the names of the Nar and the Narayena Purvatas. The former is to the east, the latter to the west, and completely covered with snow from the summit to the base.

The temple of Bhadri-Nath has more beneficed lands attached to it than any sacred Hindoo establishment in this part of India. It is said to possess seven hundred villages in different parts of Gurwhal and Kumaoon: many of them have been conferred by the government; others have been given in pledge for loans; and some few, purchased by individuals, have been presented as religious offerings.

The annual ceremony of carrying the images of their gods to wash in the sacred stream of the Jumna, is, it appears, one of much solemnity among the inhabitants of the neighborhood; and the concourse of people that here assemble, are busily engaged, and continue to be fully occupied in doing honor to it. They dance to the sound of strange music, and intoxicate themselves with a sort of vile spirit, brewed from grain and particular roots, sometimes, it is said, sharpened by pepper. The dance is most grotesque and savage; a multitude of men taking hands sometimes in a circle, sometimes in a line, beating time with their feet, bend with one accord, first nearly to the earth with their faces, then backward, and then sidewise, with various wild contortions. These, and their uncouth dress of black and gray blankets, give a peculiar air of brutal ferocity to the assemblage. The men dance all day, and in the

evening they are joined by the women, who mix indiscriminately with them, and keep up dancing and intoxication till the night is far advanced. They continue this frantic kind of worship for several days; and, in truth, it is much in unison with their general manners and habits, savage and inconsistent. At a place so sacred, the residence of so many Brahmins, and the resort of so many pilgrims, we might expect to find a strict attention to the forms of religion, and a scrupulous observance of the privations and austerities enjoined by it. So far, however, is this from the truth, that much is met with, shocking even to those Hindoos who are less bigoted.

“There were several points to be arranged,” says Mr. Fraser, “before we could set off for Gungotree, the source of the Jumna. I did not deem it proper to go unarmed; but agreed that only five men should be accoutered to attend us, and that I should myself carry my gun. But all these weapons of war were to be put aside before we got within sight of the holy spot, and deposited in a cave near it, under a guard. I also pledged myself that no use should be made of these instruments, nor any life sacrificed for the purpose of food, either by myself or by any of my people, after leaving the village, until we returned; moreover, that I would not even carry meat of any sort, dead or alive, along with me, but eat only rice and bread. As to the putting off my shoes, they did not even propose it to me, and it could not have been done; but I volunteered to put them off, when entering into the precincts of the temple and holier places, which pleased them greatly. All the Hindoos, including the Ghoorkhas, went from the village barefoot.

“Just at the end of the bridge there is an overhanging rock, under which worship is performed to Bhyram, and a black stone partly painted red, is the image of the god; and here not only were prayers and worship performed, but every one was obliged to bathe and eat bread baked by the Brahmins, as preparatory to the great and effectual ablutions at the holier Gungotree. This occupied a considerable time, as the party was numerous: in the mean time I took a very imperfect sketch of the scene, after which I bathed myself at the proper place, which is the junction of the two streams, while the Brahmin prayed over me. Among the ceremonies performed, he made me hold a tuft of grass while he prayed, which at the conclusion he directed me to throw into the eddy occasioned by the meeting of the two waters.

“By an unpleasant path we reached a step, or level spot on the first stage of the mountain, where, in a thick grove of fir-trees, is placed a small temple to Bhyram, a plain white building, built by order of Umur Sing T’happa, who gave a sum of money to repair the road, and erect places of worship here, and at Gungotree. Having paid our respects to Byramjee, we proceeded along the side of the hill on the right bank, north of the river, gradually ascending by a path equally difficult and dangerous as the first part of our ascent, but more fearful, as the precipice to the river, which rolls below us, increases in hight, and exceedingly toilsome from the nature of the ground over which it passes, and which consists wholly of sharp fragments from the cliffs above, with fallen trunks and broken branches of trees.

“The path increases in difficulty from the very irregular nature of the ground, as well as the steepness of the hill face across which it leads, ascending and descending as the small, though deep water-courses furrow the mountain side, in loose soil, formed of small fragments fallen from above, and which slip down, threatening to carry the traveler to the gulf below. The shapeless blocks of rock now more completely obstruct the way, and for hundreds of yards, at times, the passenger must clamber over these masses, heaped as they are one upon another, in monstrous confusion, and so uncertain and unsteady, that, huge though they are, they shake and move even under the burden of a man’s weight. So painful indeed is this track, that it might be conceived as meant to serve as a penance to the unfortunate pilgrims with bare feet, thus to prepare them for the special and conclusive act of piety they have in view, as the object of their journey to these extreme wilds.

“The spot which bears the name of Gungotree, is concealed by the roughness of the ground, and the masses of fallen rock, so as not to be seen till the traveler comes close upon it. The temple is situated precisely on the sacred stone on which Bhagirutte used to worship Mahadeo, and is a small building of a square shape for about twelve feet high, and rounding in, in the usual form of pagodas, to the top. It is quite plain, painted white, with red moldings, and surmounted with the usual melon-shaped ornaments of these buildings. From the eastern face of the square, which is turned nearly to the sacred source, there is a small projection covered with a stone roof, in which is the entrance facing the east, and just opposite this there is a small pagoda-shaped temple to Bhyramjee. The whole is surrounded by a wall of unhewn stone and lime, and the space this contains is paved with flat stones. In this space too, there is a comfortable but small house for the residence of the Brahmins who come to officiate. Without the inclosure there are two or three sheds constructed of wood, called _dhurum sallahs_, built for the accommodation of pilgrims who resort here; and there are many caves around formed by overhanging stones, which yield a shelter to those who can not find accommodation in the sheds.

“The scene in which this holy place is situated, is worthy of the mysterious sanctity attributed to it, and the reverence with which it is regarded. We have not here the confined gloominess of Bhyram Gattee: the actual dread which can not but be inspired by the

precipices and torrents, and perils of the place, here gives way to a sensation of awe, imposing but not embarrassing, that might be compared to the dark and dangerous pass to the center of the ruins of a former world; for, most truly, there is little here that recalls the recollection of that which we seem to have quitted. The bare and peaked cliffs which shoot to the skies, yield not in ruggedness or elevation to any we have seen; their ruins lie in wild chaotic masses at their feet, and scantier wood imperfectly relieves their nakedness: even the dark pine more rarely roots itself in the deep chasms which time has worn. Thus on all sides is the prospect closed, except in front to the eastward; where, from behind a mass of bare spires, four huge, lofty, snowy peaks arise: these are the peaks of Roodroo-Himala. There could be no finer finishing, no grander close to such a scene, as is visible in the engraving.

“We approach it through a labyrinth of enormous shapeless masses of granite, which during ages have fallen from the cliffs above, that frown over the very temple, and in all probability will some day themselves descend in ruins and crush it. Around the inclosure, and among these masses, for some distance up the mountain, a few fine old pine-trees throw a dark shade and form a magnificent foreground; while the river runs impetuously in its shingly bed, and the stifled but fearful sound of the stones which it rolls along with it, crushing together, mixes with the roar of its waters.

“It is easy to write of rocks and wilds, of torrents and precipices; it is easy to tell of the awe such scenes inspire: this style and these descriptions are common and hackneyed. But it is not so simple, to many surely not very possible, to convey an adequate idea of the stern and rugged majesty of some scenes; to paint their lonely desertness, or describe the undefinable sensation of reverence and dread that steals over the mind while contemplating the death-like, ghastly calm that is shed over them: and when at such a moment we remember our homes, our friends, our firesides, and all social intercourse with our fellows, and feel our present solitude, and far distance from all these dear ties, how vain it is to strive at description! Surely such a scene is Gungotree. [See cut, page 109.] Nor is it, independently of the nature of the surrounding scenery, a spot which lightly calls forth powerful feelings. We were now in the center of the stupendous Himalaya, the loftiest and perhaps most rugged range of mountains in the world. We were at the acknowledged source of that noble river, which is equally an object of veneration and a source of fertility, plenty and opulence to Hindoostan; and we had now reached the holiest shrine of Hindoo worship which these holy hills contain. These are surely striking considerations, combining with the solemn grandeur of the place, to move the feelings strongly.

“The fortuitous circumstance of being the first European that ever penetrated to this spot, was no matter of boast, for no great danger had been braved, no extraordinary fatigues undergone; the road is now open to any other who chooses to attempt it; but it was a matter of satisfaction to myself. The first object of inquiry that naturally occurs to the traveler, after casting a glance over the general landscape, is the source of the river. Here, as at Jumnotree, you are told that no mortal has gone, or can go further toward its extreme origin than this spot; and the difficulty is indeed very apparent. I made a trial to gain a point about two furlongs beyond the temple, both for the purpose of observing the course of the river, and of seeing Gungotree in another point of view. But having with considerable difficulty made my way over the unsteady fragments for some hundred yards, at the risk of being precipitated into the stream, I was forced to turn back.

“The source is not more than five miles’ horizontal distance from the temple, and in a direction south-east, eighty-five degrees nearly; and beyond this place it is in all probability chiefly supplied by the melting of the great bosom of snow which terminates the valley, and which lies between the peaks of the great mountain above mentioned.

“This mountain, which is considered to be the loftiest and greatest of the snowy range in this quarter, and probably yields to none in the whole Himalaya, obtains the name of Roodroo Himala, and is held to be the throne or residence of Mahadeo himself. It is also indiscriminately called Pauch Purbut, from its five peaks, and Soomeroo Purbot, which is not to be confounded with the mountain so called near Bunderbouch; and sometimes the general appellation of Kylas is given, which literally signifies any snowy hill, but is applied to this mountain by way of preëminence. It has five principal peaks, called Roodroo Himala, Burrumpooree, Bissenpooree, Oodgurre Kanta and Soorga Rounee. These form a sort of semicircular hollow of very considerable extent, filled with eternal snow, from the gradual dissolution of the lower parts of which the principal part of the stream is generated: probably there may be smaller hollows beyond the point to the right above Gungotree, which also supply a portion.

“Within the temple there are three images; one, that of Kali; and the elevated stone shelf on which they were placed was wet and soiled with the offerings made; there was a peculiar smell, but I know not whence it proceeded. The place, as usual, was lighted by a small lamp: no daylight had admittance. Just below the temple, on the river side, grew three poplar trees, and a few small larches; above there are the remains of a fine old silver fir-tree, which overshadows some of the caves and sheds. The whole people also bathed, and contributed something to the priesthood; and it was a matter of serious importance, as well as of great joy to every one, that we had thus happily reached a place of such supereminent sanctity: such, indeed, that the act of bathing here is supposed to

cleanse from every sin heretofore committed, and the difficulty of which is so great, that few, except professional devotees, ever attempt reaching the holy place.

“It is customary that those who have lost their father and mother, or either of these, shall be shaved at this spot; and it was curious to observe the whimsical changes produced by the operation, which numbers underwent. It appears also, that one chief ordinance was the going frequently round the holy temple; and we particularly observed that those who were noted as the greatest rogues were most forward in this pious exercise: one man, in particular, who had been a notorious thief, was unwearied in his perseverance.

“Well, indeed, do they say, that Seeva has made these recesses which he inhabits, inaccessible to all but those whom true devotion leads to his shrine. That man must have been indeed strongly impelled by devotion, ambition, or curiosity, who first explored the way to Gungotree. It were unavailing to inquire, and perhaps of little use, if known, to which of these motives we owe the enterprise; but patience, perseverance, and courage, must have been strongly united with it to lead him safely and successfully through those awful cliffs, that would bar the way to most men. Another omen of favor pointed out was, the increase of the river after bathing, as at Jumnotree; and it is singular enough, that during the time we remained here, I remarked several increases and decreases of the water, without any obvious causes; but these may fairly be referred to the effects of sudden changes of temperature occurring frequently among the hills, and acting on the body of snow that feeds the river.”

ASIATIC VOLCANOES.

Among the Asiatic burning mountains, a brief account of which we introduce after the above interesting notice of the grand Himalaya chain, those of Japan are both remarkable and numerous. On the summit of a mountain in the province of Figo, is a large cavern, formerly the mouth of a volcano, but the flame of which has ceased, probably for want of combustible matter. In the same province, near a religious structure called the Temple of the Jealous God of Aso, a perpetual flame issues from the top of a mountain. In the province of Tsickusen is another burning mountain, where was formerly a coal-pit, which having been set on fire by the carelessness of the workmen, has been burning ever since. Sometimes a black smoke, accompanied by a very disagreeable stench, is observed to issue from the summit of a famous mountain called Fesi, in the province of Seruga. This mountain is said to be nearly as high as the peak of Teneriffe, but in shape and beauty is supposed not to have an equal. Its top is covered with perpetual snow. Belonging to the Japanese cluster, and not far from Piranda, is a small rocky island, which has been burning and trembling for many centuries; and in another small island, opposite to Santzuma, is a volcano which has been burning at different intervals for many ages.

Captain Gore, when leaving Japan, passed by great quantities of pumice-stone, several pieces of which were taken up, and found to weigh from one ounce to three pounds. It was conjectured that these stones had been thrown into the sea by eruptions at various times, as many of them were covered by barnacles (small shells) and others were quite bare.

VOLCANIC MOUNTAINS OF KAMTSCHATKA.

There are three burning mountains of Kamtschatka, which for many years have thrown out a considerable smoke, but do not often burst into a flame. One of these is situated in the vicinity of Awatska; and another, named the volcano of Tolbatchiek, on a neck of land between the river Kamtschatka and the Tolbatchiek. In the beginning of the year 1739, the flames issued with such violence from the crater, as to reduce to ashes the forests on the neighboring mountains. This was succeeded by a cloud of smoke, which overspread and darkened the whole country, until it was dissipated by a shower of cinders, which covered the ground to the distance of thirty miles. The third volcano is on the top of the particular mountain of Kamtschatka, which is described as by far the highest in the peninsula. It rises from two rows of hills, somewhat in the form of a sugar-loaf, to a very great hight. It usually throws out ashes twice or thrice a year, sometimes in such quantities, that for three hundred versts, (one hundred and sixty-five English miles,) the earth is covered with them. In the year 1737, at the latter end of September, a conflagration, which lasted for a week, was so violent and terrific, that the mountain appeared, to those who were fishing at sea, like one red-hot rock; and the flames which burst through several openings, with a dreadful noise, resembled rivers of fire. From the inside of the mountains were heard thunderings, crackings, and blasts like those of the strongest bellows, shaking all the neighboring territory. During the night it was most terrible; but at length the conflagration ended by the mountain’s casting forth a prodigious quantity of cinders and ashes, among which were porous stones, and glass of various colors. When Captain Clarke sailed out of the harbor of St. Peter and St. Paul, in June, 1778, to the northward, an eruption of the first of these volcanoes was observed. A rumbling noise, resembling distant hollow thunder, was heard before daylight; and when the day broke, the decks and sides of the ships were covered with a

fine dust, resembling emery, nearly an inch thick, the air at the same time being charged with this substance to such a degree, that toward the mountain, which is situated to the north of the harbor, the surrounding objects were not to be distinguished. About twelve o'clock, and during the afternoon, the explosions became louder, and were followed by showers of cinders, which were in general about the size of peas, though many were picked up on the deck larger than a hazel-nut. Along with the cinders fell several small stones which had not undergone any change from the action of fire.

VOLCANIC MOUNTAIN OF ALBAY.

The following details of the dreadful eruption of the volcano of Albay, in the island of Luconia, one of the Philippines, on the first of February, 1814, are from an eye-witness of the dreadful scenes it presented.

"During thirteen years the volcano of Albay had preserved a profound silence. It was no longer viewed with that distrust and horror with which volcanoes usually inspire those who inhabit the vicinity. Its extensive and spacious brow had been converted into highly cultivated and beautiful gardens. On the first day of January last, no person reflected, in the slightest degree, upon the damages and losses which so bad a neighbor had once occasioned. Previously to the former eruptions there had been heard certain subterraneous sounds, which were presages of them. But upon the present occasion we remarked nothing, except that on the last day of January we perceived some slight shocks. In the night the shocks increased. At two in the morning one was felt more violent than those hitherto experienced. It was repeated at four, and from that time they were almost continual until the eruption commenced.

"The day broke, and I scarcely ever remarked in Camarines a more serene and pleasant morning. I observed, however, that the ridges nearest to the volcano were covered with mist, which I supposed to be the smoke of some house that might have been on fire in the night. But at eight o'clock the volcano began suddenly to emit a thick column of stones, sand, and ashes, which with the greatest velocity, was elevated into the highest regions of the atmosphere. At this sight we were filled with the utmost dread, especially when we observed that in an instant the brow of the volcano was quite covered. We had never seen a similar eruption, but were convinced that a river of fire was flowing toward us, and was about to consume us. The first thing which was done in my village was to secure some things esteemed sacred, and then we betook ourselves to flight. The swiftness with which the dreadful tide rolled toward us, did not give us time either for reflection or consultation. The frightful noise of the volcano caused great terror even in the stoutest hearts. We all ran, filled with dismay and consternation, endeavoring to reach the highest and most distant places, to preserve ourselves from so imminent a danger. The horizon began to darken, and our anxieties redoubled. The noise of the volcano continually increased, the darkness augmented, and we continued our flight. But, notwithstanding our swiftness, we were overtaken by a heavy shower of huge stones, by the violence of which many unfortunate persons were in a moment killed. This cruel circumstance obliged us to make a pause in our career, and to shelter ourselves under the houses; but the flames and burnt stones which fell from above, in a short time reduced them to ashes.

"The sky was now completely overcast, and we remained enveloped and immersed in a thick and palpable darkness. From that moment reflection was at an end. The mother abandoned her children, the husband his wife, and the children forgot their parents.

"In the houses we had no longer any shelter. It was necessary to abandon, or perish with them; yet, to go out uncovered, was to expose one's self to a danger not less imminent, because many of the stones were of an enormous size; and they fell as thick as drops of rain. It was necessary to defend ourselves as well as we could. Some covered themselves with hides, others with tables and chairs, and others with boards and tea-trays. Many took refuge in the trunks of trees, others among the canes and hedges, and some hid themselves in a cave, where the brow of a mountain protected them.

"About ten o'clock the heavy stones ceased to fall, and a rain of thick sand succeeded. At half past one the noise of the volcano began to diminish, and the horizon to clear a little; and at two it became quite tranquil; and we now began to perceive the dreadful ravages which the darkness had hitherto concealed from us. The ground was covered with dead bodies, part of whom had been killed by the stones, and the others consumed by the fire. Two hundred perished in the church of Budiao, and thirty-five in a single house in that village. The joy the living felt at having preserved themselves, was in many converted into the extremity of sorrow at finding themselves deprived of their relations and friends. Fathers found their children dead, husbands their wives, and wives their husbands, in the village of Budiao, where there were very few who had not lost some of their nearest connections. In other places we found many persons extended upon the ground, wounded or bruised in a thousand ways. Some with their legs broken, some without arms, some with their skulls fractured, and others covered with wounds. Many died immediately, others on the following days, and the rest were abandoned to the most melancholy fate, without physicians, without medicines, and in want even of

necessary food.

“Five populous towns were entirely destroyed by the eruption; more than twelve hundred of the inhabitants perished amidst the ruins; and twenty thousand who survived the awful catastrophe, were stripped of their possessions and reduced to beggary.

“The subsequent appearance of the volcanic mountain was most melancholy and terrific. Its side, formerly so well cultivated, and which afforded a prospect the most picturesque, is now become a barren sand. The stones, sand and ashes, which cover it, in some places exceed the depth of ten and twelve yards; and on the ground where lately stood the village of Budiao, there are spots in which the cocoa-trees are almost covered. In the ruined villages, and through the whole extent of the eruption, the ground remains buried in the sand to the depth of half a yard, and scarcely a single tree is left alive. The crater of the volcano has lowered more than one hundred and twenty feet; and the south side discovers a spacious and horrid mouth, which is frightful to the view. Three new ones have opened at a considerable distance from the principal crater, through which also smoke and ashes are incessantly emitted. In short, the most beautiful villages of Camarines, and the principal part of that fine province, are deeply covered with barren sand.”

ISLANDS WHICH HAVE RISEN FROM THE SEA.

Besides the convulsions of nature displayed in volcanoes, the most remarkable particulars of which we have given in our history of mountains, other operations are carried on below the fathomless depths of the sea, the nature of which can only be conjectured by the effects produced. Nor is it more astonishing that inflammable substances should be found beneath the bottom of the sea, than at similar depths on land, and that there also the impetuous force of fire should cause the imprisoned air and elastic gases to expand, and, by its mighty force, should drive the earth at the bottom of the sea above its surface. These marine volcanoes are perhaps more frequent, though they do not so often come within the reach of human observation, as those on land; and stupendous must be the operations carried on, when matter is thrown up to an extent which the ingenuity of man does not enable him to reach by fathoming.

Many instances have occurred, as well in ancient as in modern times, of islands having been formed in the midst of the sea; and their sudden appearance has constantly been preceded by violent agitations of the surrounding waters, accompanied by dreadful noises, and in some instances by fiery eruptions from the newly formed isles, which are composed of various substances, frequently intermixed with a considerable quantity of volcanic lava. Such islands remain for ages barren, but in a long course of time become abundantly fruitful. It is a matter of curious inquiry, whether springs are found on such newly created spots, when the convulsions which gave them birth have subsided; but on this point it would seem that we are not possessed of any certain information, as it does not appear that they have been visited by any naturalist with the express view of recording their properties.

Among the writers of antiquity who have transmitted accounts of islands which have thus started up to the view of the astonished spectator, Seneca asserts that, in his time, the island of Therasea, in the Egean sea, was seen to rise in this manner by several mariners, who were sailing near the point of its ascent. Pliny’s relation is still more extraordinary; for he says that in the Mediterranean, thirteen islands emerged at once from the sea, the cause of which he ascribes rather to the retiring of the waters, than to any subterraneous operation of nature: but he speaks at the same time of the island of Hiera, in the vicinity of Therasea, as having been formed by subterraneous explosions, and enumerates several others said to have been derived from a similar origin, in one of which he says, a great abundance of fishes were found, of which, however, all who ate, perished soon afterward.

It is to the Grecian archipelago, and the Azores, or Western isles, that we are to look for the grandest and most surprising instances of this phenomenon. We will select an example from each of these groups of islands, beginning with the latter.

In December, 1720, a violent earthquake was felt on the island of Tercera, one of the Azores. And on the following morning, a new island, which had sprung up in the night, made its appearance, and a huge column of smoke was seen rising from it. The pilot of a ship which attempted to approach it, sounded on one of these newly formed islands, with a line of sixty fathoms, but could not find a bottom. On the opposite side, the sea was deeply tinged with various colors, white, blue and green; and was very shallow. This island was larger on its first appearance than at some distance of time afterward; it at length sunk beneath the level of the sea, and is now no longer visible.

What can be more surprising than to see fire, not only force its way out of the bowels of the earth, but likewise make for itself a passage through the waters of the sea! What can be more extraordinary, or foreign to our common notions of things, than to observe the bottom of the sea rise up in a mountain above its surface, and become so firm an island as to be able to resist the

violence of the greatest storms! We know that subterraneous fires, when pent up in a narrow passage, are able to elevate a mass of earth as large as an island; but that this should be done in so regular and precise a manner, that the water of the sea should not be able to penetrate and extinguish those fires; and that, after they should have exhausted themselves, the mass of earth should not fall down, or sink again with its own weight, but still remain in a manner suspended over the great arch below; this seems more surprising than any of the facts which have been related of Mount Etna, Vesuvius, or any other volcano.

In the first part of the Transactions of the Royal Society for the year 1812, Captain Tillard, of the British navy, has published a very interesting narrative of a similar phenomenon, which occurred in the same sea near the Azores. We give this narrative in his own words.

“Approaching the island of St. Michael’s, on Sunday, the twelfth of June, 1811, in his majesty’s sloop Sabrina, under my command, we occasionally observed, rising in the horizon, two or three columns of smoke, such as would have been occasioned by an action between two ships, to which cause we universally attributed its origin. This opinion was, however, in a very short time changed, from the smoke increasing and ascending in much larger bodies than could possibly have been produced by such an event; and having heard an account, prior to our sailing from Lisbon, that in the preceding January or February, a volcano had burst out within the sea near St. Michael’s, we immediately concluded that the smoke we saw proceeded from that cause, and, on our anchoring the next morning in the road of Ponta del Gada, we found this conjecture correct as to the cause, but not as to the time; the eruption of January having totally subsided, and the present one having only burst forth two days prior to our approach, and about three miles distant from the one before alluded to.

“Desirous of examining as minutely as possible a contention so extraordinary between two such powerful elements, I set off from the city of Ponta del Gada on the morning of the fourteenth, in company with Mr. Read, the consul-general of the Azores, and two other gentlemen. After riding about twenty miles across the north-west end of the island of St. Michael’s, we came to the edge of the cliff, whence the volcano burst suddenly upon our view in the most terrific and awful grandeur. [See cut, page 122.] It was only a short mile from the base of the cliff, which was nearly perpendicular, and formed the margin of the sea; this cliff being, as nearly as I could judge, from three to four hundred feet high. To give you an adequate idea of the scene by description, is far beyond my powers; but for your satisfaction, I shall attempt it.

[Illustration: ST. MICHAEL’S VOLCANO.]

“Imagine an immense body of smoke rising from the sea, the surface of which was marked by the slippery rippling of the waves, occasioned by the light and steady breezes incidental to these climates in summer. In a quiescent state, it had the appearance of a circular cloud revolving on the water like a horizontal wheel, in various and irregular involutions, expanding itself gradually on the lee side, when suddenly a column of the blackest cinders, ashes and stones would shoot up in the form of a spire, at an angle of from ten to twenty degrees from a perpendicular line, the angle of inclination being universally to windward; this was rapidly succeeded by a second, third and fourth shower, each acquiring greater velocity, and overtopping the other till they had attained an altitude as much above the level of our eye, as the sea was below it.

“As the impetus with which the columns were severally propelled diminished, and their ascending motion had nearly ceased, they broke into various branches resembling a group of pines; these again forming themselves into festoons of white feathery smoke, in the most fanciful manner imaginable, intermixed with the finest particles of falling ashes, which at one time assumed the appearance of innumerable plumes of black and white ostrich feathers, surmounting each other, and another, that of the light wavy branches of a weeping-willow.

“During these bursts, the most vivid flashes of lightning continually issued from the densest part of the volcano; and the cloud of smoke, now ascending to an altitude much above the highest point to which the ashes were projected, rolled off in large masses of fleecy clouds, gradually expanding themselves before the wind in a direction nearly horizontal, and drawing up to them a quantity of water-spouts, which formed a most beautiful and striking addition to the general appearance of the scene.

“That part of the sea where the volcano was situated, was upward of thirty fathoms deep, and at the time of our viewing it the volcano was only four days old. Soon after our arrival on the cliff, a peasant observed he could discern a peak above the water: we looked but could not see it; however, in less than half an hour it was plainly visible, and before we quitted the place, which was about three hours from the time of our arrival, a complete crater was formed above the water, not less than twenty feet high on the side where the greatest quantity of ashes fell; the diameter of the crater being apparently about four or five hundred feet.

“The great eruptions were generally attended with a noise like the continued firing of cannon and musketry intermixed, as also with slight shocks of earthquakes; several of which having been felt by my companions, but none by myself, I had become half skeptical, and thought their opinion arose merely from the force of imagination; but while we were sitting within five or six yards of the edge of the cliff, partaking of a slight repast which had been brought with us, and were all busily engaged, one of the most magnificent bursts took place which we had yet witnessed, accompanied by a very severe shock of an earthquake. The instantaneous and involuntary movement of each was to spring upon his feet; and I said, ‘This admits of no doubt.’ The words had scarcely passed my lips, before we observed a large portion of the face of the cliff, about fifty yards on our left, falling, which it did with a violent crash. So soon as our first consternation had a little subsided, we removed about ten or a dozen yards further from the edge of the cliff, and finished our dinner.

“On the succeeding day, June fifteenth, having the consul and some other friends on board, I weighed, and proceeded with the ship toward the volcano, with the intention of witnessing a night view; but in this expectation we were greatly disappointed, from the wind freshening, and the weather becoming thick and hazy, and also from the volcano itself being more quiescent than it was the preceding day. It seldom emitted any lightning, but occasionally as much flame as may be seen to issue from the top of a glass-house or foundry chimney. On passing directly under the great cloud of smoke, about three or four miles distant from the volcano, the decks of the ship were covered with fine black ashes, which fell intermixed with small rain. We returned the next morning, and late on the evening of the same day I took leave of St. Michael’s, to complete my cruise.

“On the opening of the volcano clear of the north-west part of the island, after dark on the sixteenth, we witnessed one or two eruptions that, had the ship been near enough, would have been awfully grand. It appeared one continued blaze of lightning; but its distance from the ship, upward of twenty miles, prevented our seeing it with effect. Returning again toward St. Michael’s, on the fourth of July, I was obliged, by the state of the wind, to pass with the ship very close to the island, which was now completely formed by the volcano, being nearly the hight of Matlock High Tor, about eighty yards above the sea. At this time it was perfectly tranquil; which circumstance determined me to land, and explore it more narrowly. I left the ship in one of the boats, accompanied by some of the officers. As we approached we perceived that it was still smoking in many parts, and, upon our reaching the island, found the surf on the beach very high. Rowing round to the lee-side, with some little difficulty, by the aid of an oar as a pole, I jumped on shore, and was followed by the other officers. We found a narrow beach of black ashes, from which the side of the island rose in general too steep to admit of our ascending; and where we could have clambered up, the mass of matter was much too hot to allow our proceeding more than a few yards in the ascent.

“The declivity below the surface of the sea was equally steep, having seven fathoms of water at scarcely the boat’s length from the shore, and at the distance of twenty or thirty yards we sounded twenty-five fathoms. From walking round it in about twelve minutes, I should judge that it was something less than a mile in circumference; but the most extraordinary part was the crater, the mouth of which, on the side facing St. Michael’s, was nearly level with the sea. It was filled with water, at that time boiling, and was emptying itself into the sea by a small stream about six yards over, and by which I should suppose it was continually filled again at high water. This stream, close to the edge of the sea, was so hot, as only to admit the finger to be dipped suddenly in, and taken out again immediately.

“It appeared evident, by the formation of this part of the island, that the sea had, during the eruptions, broken into the crater in two places, as the east side of the small stream was bounded by a precipice; a cliff between twenty and thirty feet high, forming a peninsula of about the same dimension in width, and from fifty to sixty feet long, connected with the other part of the island by a narrow ridge of cinders and lava, as an isthmus, of from forty to fifty feet in length, from which the crater rose in the form of an amphitheater.

“This cliff, at two or three miles’ distance from the island, had the appearance of a work of art, resembling a small fort or block-house. The top of this we were determined, if possible, to attain; but the difficulty we had to encounter in doing so, was considerable: the only way to attempt it was up the side of the isthmus, which was so steep that the only mode by which we could effect it, was by fixing the end of an oar at the base, with the assistance of which we forced ourselves up in nearly a backward direction.

[Illustration: SABRINA ISLAND.]

“Having reached the summit of the isthmus, we found another difficulty: for it was impossible to walk upon it, as the descent on the other side was immediate, and as steep as the one we had ascended; but by throwing our legs across it, as would be done on the

ridge of a house, and moving ourselves forward by our hands, we at length reached that part of it where it gradually widened itself, and formed the summit of the cliff, which we found to have a perfectly flat surface, of the dimensions before stated. Judging this to be the most conspicuous situation, we here planted the union, and left a bottle sealed up, containing a short account of the origin of the island, and of our having landed upon it, and naming it Sabrina island.

“Within the crater I found the complete skeleton of a guard-fish, the bones of which, being perfectly burnt, fell to pieces upon attempting to take them up; and, by the account of the inhabitants on the coast of St. Michael’s, great numbers of fish had been destroyed during the early part of the eruption, as large quantities, probably suffocated or poisoned, were occasionally found drifted into the small inlets or bays. The island, like other volcanic productions, is composed principally of porous substances, generally burnt to complete cinders, with occasional masses of a stone, which I should suppose to be a mixture of iron and limestone.”

Sabrina island has gradually disappeared, since the month of October, 1811, leaving an extensive shoal. Smoke was discovered still issuing out of the sea in the month of February, 1812, near the spot where this wonderful phenomenon appeared.

Having thus spoken of the Azores, we now pass to some similar phenomena in the Grecian archipelago. Before entering, however, on the details which are here furnished on this curious and most interesting subject, it may not be improper to observe, that the island of Acroteri, of great celebrity in ancient history, appears to have its surface composed of pumice-stone, incrusted by a surface of fertile earth; and that it is represented by the ancients as having risen, during a violent earthquake, from the sea. Four neighboring islands are described as having a similar origin, notwithstanding the sea is in that part of the archipelago of such a depth as to be unfathomable by any sounding line. These arose at different times: the first long before the commencement of the Christian era; the second in the first century; the third in the eighth; and the fourth in 1573.

We now proceed to a phenomenon of a similar nature, belonging to the same cluster of islands, which being of a more recent date, we are enabled to enter into all its particulars. They are such as can not fail to interest and surprise.

On the twenty-second of May, 1707, a severe earthquake was felt at Stanchio, an island of the archipelago; and on the ensuing morning a party of seamen, discovering not far off what they believed to be a wreck, rapidly rowed toward it; but finding rocks and earth instead of the remains of a ship, hastened back, and spread the news of what they had seen, in Santorini, another of these islands. However great the apprehensions of the inhabitants were at the first sight, their surprise soon abated, and in a few days, seeing no appearance of fire or smoke, some of them ventured to land on the new island. Their curiosity led them from rock to rock, where they found a kind of white stone, which yielded to the knife like bread, and nearly resembled that substance in color and consistence. They also found many oysters sticking to the rocks: but while they were employed in collecting them, the island moved and shook under their feet, on which they ran with precipitation to their boats. Amid these motions and tremblings the island increased, not only in hight, but in length and breadth: still occasionally, while it was raised and extended on the one side, it sunk and diminished on the other. One person observed a rock to rise out of the sea, forty or fifty paces from the island, which, having been thus visible for four days, sunk, and appeared no more: several others appeared and disappeared alternately, till at length they remained fixed and unmoved. In the mean time the color of the surrounding sea was changed: at first it was of a light green, then reddish, and afterward of a pale yellow, accompanied by a noisome stench, which spread itself over a part of the island of Santorini.

On the sixteenth of July, smoke first appeared, not indeed on the island, but issuing from a ridge of black stones which suddenly rose about sixty paces from it, where the depth of the sea was unfathomable. Thus there were two separate islands, one called the White, and the other the Black island, from the different appearances they exhibited. This thick smoke was of a whitish color, like that of a lime-kiln, and was carried by the wind to Santorini, where it penetrated the houses of the inhabitants.

In the night between the nineteenth and twentieth of July, flames began to issue with the smoke, to the great terror of the inhabitants of Santorini, especially of those occupying the castle of Scaro, who were distant about a mile and a half only from the burning island, which now increased very fast, large rocks daily springing up, which sometimes added to its length, and sometimes to its breadth. The smoke, also increased, and there not being any wind, ascended so high as to be seen at Candia, and other distant islands. During the night, it resembled a column of five, fifteen, or twenty feet in hight; and the sea was then covered with a scurf or froth, in some places reddish, and in others yellowish, from which proceeded such a stench, that the inhabitants throughout the whole island of Santorini burnt perfumes in their houses, and made fires in the streets, to prevent infection. This, indeed, did not last above a day or two; for a strong gale of wind dispersed the froth, but drove the smoke on the vineyards of Santorini, by which the grapes were, in one night, parched up and destroyed. This smoke also caused violent head-aches, attended with retchings.

On the thirty-first of July, the sea smoked and bubbled in two different places near the island, where the water formed a perfect circle, and looked like oil when beginning to simmer. This continued above a month, during which time many fishes were found dead on the shore of Santorini. On the following night a dull hollow noise was heard, like the distant report of several cannon, which was instantly followed by flames of fire, shooting up to a great hight in the air, where they suddenly disappeared. The next day the same hollow sound was several times heard, and succeeded by a blackish smoke, which, notwithstanding a fresh gale blew at the time, rose up to a prodigious hight, in the form of a column, and would probably in the night have appeared as if on fire.

On the seventh of August, a different noise was heard, resembling that of large stones thrown, at very short intervals, into a deep well. This noise, having lasted for some days, was succeeded by another much louder, so nearly resembling thunder, as scarcely to be distinguished from three or four real claps, which were heard at the same time.

On the twenty-first, the fire and smoke were very considerably diminished; but the next morning they broke out with still greater fury than before. The smoke was red, and very thick, the heat at the same time being so intense, that all around the island the sea smoked and bubbled surprisingly. At night, by the means of a telescope, sixty small openings or funnels, all emitting a very bright flame, were discovered on the highest part of the island, conjointly resembling a large furnace; and on the other side of the great volcano there appeared to be as many.

On the morning of the twenty-third, the island was much higher than on the preceding day, and its breadth increased by a chain of rocks which had sprung up in the night nearly fifty feet above the water. The sea was also again covered with reddish froth, which always appeared when the island seemed to have received any considerable additions, and occasioned an intolerable stench, until it was dispersed by the wind and the motion of the waves.

On the fifth of September, the fire opened another vent at the extremity of the Black island, from which it issued for several days. During that time little was discharged from the large furnace; but from this new passage the astonished spectator beheld the fire dart up three several times to a vast hight, resembling so many prodigious sky-rockets of a glowing, lively red. The following night the sub-aqueous fire made a terrible noise, and immediately, after a thousand sheaves of fire darted into the air, where breaking and dispersing, they fell like a shower of stars on the island, which appeared in a blaze, presenting to the amazed spectator at once a most dreadful and beautiful illumination. To these natural fire-works, succeeded a kind of meteor, which for some time hung over the castle of Scaro, and which, having a resemblance to a flaming sword, served to increase the consternation of the inhabitants of Santorini.

On the ninth of September, the White and Black islands united; after which the western end of the island grew daily in bulk. There were now four openings only which emitted flames; these issued forth with great impetuosity, sometimes attended with a noise like that of a large organ-pipe, and sometimes like the howling of wild beasts.

On the twelfth, the subterraneous noise was much augmented, having never been so frequent or so dreadful as on that and the following day. The bursts of this subterraneous thunder, like a general discharge of the artillery of an army, were repeated ten or twelve times within twenty-four hours, and, immediately after each clap, the large furnace threw up huge red-hot stones, which fell into the sea at a great distance. These claps were always followed by a thick smoke, which spread clouds of ashes over the sea and the neighboring islands.

On the eighteenth of September, an earthquake was felt at Santorini. It did but little damage, although it considerably enlarged the burning island, and in several places gave vent to the fire and smoke. The claps were also more terrible than ever; and, in the midst of a thick smoke, which appeared like a mountain, large pieces of rock, which afterward fell on the island, or into the sea, were thrown up with as much noise and force as balls from the mouth of a cannon. One of the small neighboring islands was covered with these fiery stones, which being thinly crusted over with sulphur, gave a bright light, and continued burning until that was consumed.

On the twenty-first, a dreadful clap of subterraneous thunder was followed by very powerful lightnings, and at the same instant the new island was so violently shaken, that part of the great furnace fell down, and huge burning rocks were thrown to the distance of two miles and upward. This seemed to be the last effort of the volcano, and appeared to have exhausted the combustible matter, as all was quiet for several days after: but on the twenty-fifth, the fire broke out again with still greater fury, and among the claps one was so terrible, that the churches of Santorini were soon filled with crowds of people, expecting every moment to be their last; and the castle and town of Scaro suffered such a shock, that the doors and windows of the houses flew open. The volcano continued to rage during the remaining part of the year; and in the month of January, 1708, the large furnace, without one day’s

intermission, threw out stones and flames, at least once or twice, but generally five or six times a day.

On the tenth of February, in the morning, a pretty strong earthquake was felt at Santorini, which the inhabitants considered as a prelude to greater commotions in the burning island; nor were they deceived, for soon after the fire and smoke issued in prodigious quantities. The thunder-like claps were redoubled, and all was horror and confusion: rocks of an amazing size were raised up to a great hight above the water; and the sea raged and boiled to such a degree as to occasion great consternation. The subterraneous bellowings were heard without intermission, and sometimes in less than a quarter of an hour, there were six or seven eruptions from the large furnace. The noise of repeated claps, the quantity of huge stones which flew about on every side, the houses at Santorini tottering to their very foundations, and the fire, which now appeared in open day, surpassed all that had hitherto happened, and formed a scene terrific and astonishing beyond description.

The fifteenth of April was rendered memorable by the number and violence of the bellowings and eruptions, by one of which nearly a hundred stones were thrown at the same instant into the air, and fell again into the sea at about two miles distant. From that day until the twenty-second of May, which may be considered as the anniversary of the birth of the new island, things continued much in the same state, but afterward the fire and smoke subsided by degrees, and the subterraneous thunders became less terrible.

On the fifteenth of July, 1709, the Bishop of Santorini, accompanied by several friars, hired a boat to take a near view of the island. They made directly toward it on that side where the sea did not bubble, but where it smoked very much. Being within the range of this vapor, they felt a close, suffocating heat, and found the water very hot; on which they directed their course toward a part of the island at the furthest distance from the large furnace. The fires, which still continued to burn, and the boiling of the sea, obliged them to make a great circuit, notwithstanding which they felt the air about them to be very hot and sultry. Having encompassed the island, and surveyed it carefully from an adjacent one, they judged it to be two hundred feet above the sea, about a mile broad, and five miles in circumference; but, not being thoroughly satisfied, they resolved to make an attempt at landing, and accordingly rowed toward that part of the island where they perceived neither fire nor smoke. When, however, they had proceeded to within the distance of a hundred yards, the great furnace discharged itself with its usual fury, and the wind blew upon them so dense a smoke, and so heavy a shower of ashes, that they were obliged to abandon their design. Having retired somewhat further, they let down their sounding lead, with a line ninety-five fathoms in length, but it was too short to reach the bottom. On their return to Santorini, they observed that the heat of the water had melted the greater part of the pitch employed in calking their boat, which had now become very leaky.

From that time until the fifteenth of August, the fire, smoke and noises continued, but not in so great a degree; and it appears that for several years after, the island still increased, but that the fire and subterraneous noises were much abated. The most recent account we have been enabled to collect, is that of a traveler, who, in 1811, passed this island at some distance. It appeared to him like a stupendous mass of rock, but was not inhabited or cultivated. It had then long ceased to burn.

SUBTERRANEAN WONDERS.

THE GROTTA DEL CANE.

“Give me, ye powers, the wondrous scenes to show, Concealed in darkness in the caves below.”

Among the various subterranean wonders of the world, which are worthy of special notice, we would first mention the “Grotta del Cane.” This name has been given to a small cavern between Naples and Pozzuoli, on this account, that if a dog be brought into it, and his nose held to the ground, a difficulty of respiration instantly ensues, and he loses all sensation and even life, if he be not speedily removed into purer air. There are other grottos endowed with the same deleterious quality, especially in volcanic countries; and the pestiferous vapors they exhale, are quickly fatal both to animals and man, though they do not offer to the eye the slightest indication of their presence. These vapors are, however, for the greater part temporary; while that of the Grotta del Cane is perpetual, and seems to have produced its deadly effects even in the time of Pliny. A man standing erect within, does not suffer from it, the mephitic vapor rising to a small hight only from the ground. It may, therefore, be entered without danger.

The smoke of a torch extinguished in this vapor, or gas, sinks downward, assumes a whitish color, and passes out at the bottom of the door. The reason of this is, that the fumes which proceed from the torch mix more readily with the gas than with the

atmospherical air. It has been supposed, that the mischievous effects of the vapor were the result of the air being deprived of its elasticity; but it has been clearly demonstrated by M. Adolphus Murray, that they are solely to be attributed to the existence of carbonic acid gas.

The person who is the keeper, or guide, at the grotto, and who shows to strangers the experiment of the dog for a gratuity, takes the animal, when he is half dead and panting, into the open air, and then proceeds to throw him into the neighboring lake of Agnano, thus insinuating that this short immersion in the water is necessary to his complete restoration. This, however, is a mere trick, to render the experiment more specious, and to obtain a handsome present from the credulous, the atmospherical air alone sufficing for that purpose.

The celebrated naturalist, the Abbe Spallanzani, projected a regular series of experiments on the mephitic vapor of this grotto, from a persuasion that they would tend to throw a new light on physiology and natural philosophy. Being, however, prevented from undertaking this, by his duties as a professor, his friend, the Abbe Breislak, who resided near the spot, engaged in the task; and the following is an abstract of his learned memoir on this subject.

It is well known, the abbe observes, that the mephitic vapor occupies the floor of a small grotto near the lake Agnano, a place highly interesting to naturalists from the phenomena its environs present, and the hills within which it is included. This grotto is situated on the south-east side of the lake, at a little distance from it. Its length is about twelve feet, and its breadth from four to five. It appears to have been originally a small excavation, made for the purpose of obtaining pozzuolana, an earth which, being applied as mortar, becomes a powerful cement. In the sides of the grotto, among the earthy volcanic matters, are found pieces of lava, of the same kind with those which are met with scattered near the lake.

The abbe is persuaded that, if new excavations were to be made in the vicinity of the grotto, at a level with its floor, or a little lower, the same mephitic vapor would be found; and thinks it would be curious to ascertain the limits of its extent. It would also be advantageous to physical observations, if the grotto were to be somewhat enlarged, and its floor reduced to a level horizontal plane, by sinking it two or three feet, and surrounding it by a low wall, with steps at the entrance. In its present state it is extremely inconvenient for experiments, and the inclination of the ground toward the door causes a great part of the vapor, from the effect of its specific gravity, to make its way out close to the ground.

When the narrow limits of this place are considered, and the small quantity of the vapor which has rendered it so celebrated, there can not be any doubt but that it has undergone considerable changes; since it does not appear probable that Pliny refers to the present confined vapor only, when, in enumerating many places from which a deadly air exhaled, he mentions the territory of Pozzuoli. The internal fermentations by which it is caused, are certainly much diminished in the vicinity of the lake Agnano. The water near its banks is no longer seen to bubble up, from the disengagement of a gas, as it appears from accounts, not of very remote antiquity, to have done. The borders of the lake were attentively examined by the abbe, when its waters were at the highest, and after heavy rains; but he could never discover a single bubble of air. A number of aquatic insects which sport on the surface, may at first sight occasion some deception; but a slight observation soon detects the error. If, therefore, we do not suppose those authors who have described the ebullition of the water near the banks of the lake Agnano to have been deceived, it must at least be confessed, that this phenomenon has now ceased. The quantity of the sulphureous vapors which rise in the contiguous stoves, called the stoves of St. Germano, must likewise be greatly diminished from what it anciently was: for, adjoining to the present stoves, we still find the remains of a spacious ancient fabric, with tubes of _terra cotta_ inserted in the walls, which, by their direction, show for what purpose they were intended. It appears certain, that this was a building in which, by the means of pipes properly disposed, the vapors of the place were introduced into different rooms for the use of patients. To these ruins, however, the vapors no longer extend; so that, if this edifice had remained entire, it could not have been employed for the purpose for which it was intended. The veins of pyrites which produced the more ancient conflagrations of the Phlegrean fields, between Naples and Cuma, and which, in some places, are entirely consumed, approach their total extinction. We will now proceed to the experiments within the grotto.

The object of the first was to determine the hight of the mephitic vapor at the center of the grotto, that is, at the intersection of the line of its greatest length with that of its greatest breadth. The hight varies according to the different dispositions and temperatures of the atmosphere, the diversity of winds, and the accidental variations which take place in the internal fermentations by which the vapor is produced. It may, however, be estimated at a mean, at nearly nine English inches.

The second set of experiments regarded the degree of heat on entering into the mephitis: it was slightly sensible in the feet and lower part of the legs; notwithstanding which, on taking out of the vapor several substances which had remained in it for a long time, such as stones, leaves, the carcasses of animals, &c., the abbe found that these were of the same temperature with the atmospheric air. Feeling in his body a slight degree of heat, which he could not perceive in the substances removed from the mephitic vapor, he was led by comparison to conclude, that the temperature of the latter was the same with the atmospherical air, agreeably to the principles of Dr. Crauford. He was, however, mistaken; for in subsequent experiments, he found a very distinct degree of heat. He was now provided with a thermometer, his former one having been broken, and, having suspended it at the aperture of the grotto, three feet above the surface of the vapor, found the mercury to stand at from sixty-two to sixty-four degrees of Fahrenheit; but, on placing the ball on the ground so as to immerse it in the vapor, the mercury rose to eighty, and even eighty-two degrees. That the substances taken out of the mephitis did not exhibit this diversity of temperature, was, he thinks, owing to the quantity of humidity with which they are always loaded, and which produces on their surface a constant evaporation. He was the more particular in repeating these experiments, because the naturalists who had, before him, made similar ones in the Grotta del Cane, had not observed the vapor to produce any effect on the mercury in the thermometer.

Thirdly. He repeated for his own satisfaction, the usual experiments made by naturalists, with the tincture of turnsole, lime-water, the crystallizations of alkalies, the absorption of water, and the acidulous taste communicated to it; which prove, beyond all doubt, the existence of fixed air, or carbonic acid gas, in the vapor of the grotto. He ascertained that it was not formed of fixed air alone, as might have been conjectured; but that the relative quantities of the different gases which compose its mephitic air, are as follows: in one hundred parts there are ten of vital air, or oxygen gas; forty of fixed air, or carbonic acid gas; and fifty of phlogisticated air, or azotic gas.

Fourthly. The phenomena of magnetism and electricity were investigated by the abbe in this grotto. With respect to the former, there was not any new appearance: the magnetic needle, being placed on the ground, and consequently immersed in the mephitis, rested in the direction of its meridian, and, at the approach of a magnetized bar, exhibited the usual effects of attraction and repulsion, in proportion as either pole was presented. As to the latter, electricity, it was impossible to make the experiments within the mephitis, not because this kind of air is a conductor of the electric fluid, as has been imagined, but because the humidity by which it is constantly accompanied, disperses the electric matter; and this, not being collected in a conductor, can not be rendered sensible. He attempted several times to fire inflammable gas, with electric sparks, in the mephitic vapor, by means of the conductor of the electrophus; but, notwithstanding his utmost endeavors to animate the electricity, he could never obtain a single spark, the non-conductor becoming a conductor the moment it entered into the mephitis, on account of the humidity which adhered to its surface.

Fifthly. His latest experiments were directed to the theory of the combustion of bodies. He first endeavored to ascertain whether those spontaneous inflammations that result from the mixture of concentrated acids with essential oils, could be obtained within the grotto. He placed on the ground a small vessel, in such a situation that the mephitis rose six inches above its edges, employing oil of turpentine, and the vitriolic and nitrous acids: the same inflammation, accompanied by a lively flame, followed, as would have taken place in the open atmospheric air. The dense smoke which always accompanies these inflammations, being attracted by the humidity of the mephitis, presented its undulations to the eye, and formed a very pleasing object. As he had put a considerable quantity of acid in the vessel, he repeatedly poured in a little of the oil, and the flame appeared in the mouth of the vessel fifteen times successively. The oxygenous principle contained in the acids, and with which the nitrous acid principally abounds, undoubtedly contributed to the production and duration of this flame, though enveloped in an atmosphere inimical to inflammation.

The abbe had, in the district of Latera, observed that in a mephitis of hydrogenous sulphurated or hepatic gas a slow combustion of phosphorus took place, with the same resplendence as in the atmospheric air. On the present occasion, his first experiment, in the mephitis of Agnano, was made with common phosphoric matches, five of which he broke, holding them to the ground, and consequently immersed in the mephitis. They produced a short and transient flame, which became extinguished the moment it was communicated to the wick of a candle. His second experiment was as follows: he placed on the ground, within the grotto, a long table, in such a manner that one extremity was without the mephitis, while the other, and four-fifths of its length, were immersed in it. Along this table he laid a train of gunpowder, beginning from the end without the mephitis; and, at the other end, which was immersed in it to the depth of seven inches, he placed, adjoining to the gunpowder, a cylinder of phosphorus, eight lines in length. The gunpowder, without the mephitis, being fired, the combustion was soon communicated to the other extremity of the train, and to the phosphorus, which took fire with decrepitation, burned rapidly with a bright flame, slightly colored with yellow and green, and left on the wood a black mark, as of charcoal. The combustion lasted nearly two minutes, when the whole phosphoric matter was

consumed.

In succeeding experiments not any alteration was perceptible in the flame, or manner of burning, of the lighted phosphorus, either at the moment of its entrance into the mephitis, or during its continuance in it. When suddenly withdrawn, it ignited gunpowder equally well. Hence the abbe deduces, that the mephitic gas of Grotta del Cane, however it may be utterly unfit for the respiration of animals, and for the inflammation of common combustible substances, readily allows that of phosphorus, which not only burns in it, but emits, as usual, luminous sparks.

[Illustration: GROTTO OF ANTIPAROS.]

GROTTO OF ANTIPAROS.

Antiparos, one of the Cyclades, is situated in the Egean sea, or Grecian archipelago. It is a small island, about sixteen miles in circumference, and lies two miles to the west of the celebrated Paros, from which circumstance it derives its name, _anti_ in the Greek language signifying _opposite to_. Its singular and most interesting grotto, though so inferior in size to the cavern in Kentucky of which we shall soon speak, has attracted the attention of an infinite number of travelers. The entrance to this superb grotto is on the side of a rock, and is a large arch, formed of craggy stones, overhung with brambles and creeping plants, which bestow on it a gloominess at once awful and agreeable. Having proceeded about thirty paces within it, the traveler enters a low, narrow alley, surrounded on every side by stones, which, by the light of torches, glitter like diamonds; the whole being covered and lined throughout with small crystals, which give by their different reflections, a variety of colors. At the end of this alley or passage, having a rope tied round his waist, he is led to the brink of an awful precipice, and is thence lowered into a deep abyss, the gloom pervading which makes him regret the “alley of diamonds” he has just quitted. He has not yet, however, reached the grotto, but is led forward about forty paces, beneath a roof of rugged rocks, amid a scene of terrible darkness, and at a vast depth from the surface of the earth, to the brink of another precipice, much deeper and more awful than the former.

Having descended this precipice, which is not accomplished without considerable difficulty, the traveler enters a passage, the grandeur and beauty of which can be but imperfectly described. It is one hundred and twenty feet in length, about nine feet high, and in width seven, with a bottom of a fine green glossy marble. The walls and arched roof are as smooth and polished as if they had been wrought by art, and are composed of a fine glittering red and white granite, supported at intervals by columns of a deep blood-red shining porphyry, which, by the reflection of the lights, presents an appearance inconceivably grand. At the extremity of this passage is a sloping wall, formed of a single mass of purple marble, studded with sprigs of rock crystal, which, from the glow of the purple behind, appear like a continued range of amethysts.

Another slanting passage, filled with petrifactions, representing the figures of snakes and other animals, and having toward its extremity two pillars of beautiful yellow marble, which seem to support the roof, leads to the last precipice, which is descended by means of a ladder. The traveler, who has descended to the depth of nearly fifteen hundred feet beneath the surface, now enters the magnificent grotto, to procure a sight of which he has endured so much fatigue. It is in width three hundred and sixty feet; in length three hundred and forty; and in most places one hundred and eighty in hight. By the aid of torch-light, he finds himself beneath an immense and finely vaulted arch, overspread with icicles of white shining marble, many of them ten feet in length, and of a proportionate thickness. Among these are suspended a thousand festoons of leaves and flowers, of the same substance, but so glittering as to dazzle the sight. The sides are planted with petrifactions, also of white marble, representing trees; these rise in rows one above the other, and often inclose the points of the icicles. From them also hang festoons, tied as it were one to another, in great abundance; and in some places rivers of marble seem to wind through them. In short, these petrifactions, the result of the dripping of water for a long series of ages, nicely resemble trees and brooks turned to marble. The floor is paved with crystals of different colors, such as red, blue, green and yellow, projecting from it, and rendering it rugged and uneven. These are again interspersed with icicles of white marble, which have apparently fallen from the roof, and are there fixed. To these the guides fasten their torches; and the glare of splendor and beauty which results from such an illumination, may be better conceived than described.

To the above description we subjoin an extract from the one given by Dr. Clarke, a learned traveler, who visited this celebrated grotto.

“The mode of descent is by ropes, which, on the different declivities, are either held by the guides, or are joined to a cable which is fastened at the entrance around a stalactite pillar. In this manner, we were conducted, first down one declivity, and then down another, until we entered the spacious chambers of this truly enchanted grotto. The roof, the floor, the sides, of a whole series of

magnificent caverns, were entirely invested with a dazzling incrustation as white as snow. Columns, some of which were five and twenty feet in length, pended in fine icicle forms above our heads: fortunately some of them are so far above the reach of the numerous travelers, who during many ages, have visited this place, that no one has been able to injure or remove them. Others extended from the roof to the floor, with diameters equal to that of the mast of a first-rate ship of the line. The incrustations of the floor, caused by falling drops from the stalactites above, had grown up into dendritic and vegetable forms, which first suggested to Tournefort the strange notion of his having here discovered the vegetation of stones. Vegetation itself has been considered as a species of crystallization; and as the process of crystallization is so surprisingly manifested by several phenomena in this grotto, some analogy may perhaps be allowed to exist between the plant and the stone; but it can not be said, that a principle of life existing in the former has been imparted to the latter. The last chamber into which we descended surprised us more by the grandeur of its exhibition than any other. Probably there are many other chambers below this, yet unexplored, for no attempt has been made to penetrate further: and, if this be true, the new caverns, when opened, would appear in perfect splendor, unsullied, in any part of them, by the smoke of torches, or by the hands of intruders."

CAVERNS IN GERMANY AND HUNGARY,

CONTAINING FOSSIL BONES.

Among the most remarkable of these caverns are those of Gaylenreuth, on the confines of Bayreuth. The opening to these, which is about seven feet and a half high, is at the foot of a rock of limestone of considerable magnitude, and in its eastern side. Immediately beyond the opening is a magnificent grotto, of about three hundred feet in circumference, which has been naturally divided by the form of the roof into four caves. The first is about twenty-five feet long and wide, and varies in hight from nine to eighteen feet, the roof being formed into irregular arches. Beyond this is the second cave, about twenty-eight feet long, and of nearly the same width and hight with the former.

A low and very rugged passage, the roof of which is formed of projecting pieces of rocks, leads to the third grotto, the opening into which is a hole three feet high, and four feet wide. This grotto is more regular in its form, and is about thirty feet in diameter, and nearly round; its hight is from five to six feet. It is very richly and fantastically adorned by the varying forms of its stalactitic hangings. The floor is also covered with a wet and slippery glazing, in which several teeth and jaws appear to have been fixed.

From this grotto commences the descent to the inferior caverns. Within only about five or six feet an opening in the floor is seen, which is partly vaulted over by a projecting piece of rock. The descent is about twenty feet. This cavern is about thirty feet in hight, about fifteen feet in width, and nearly circular; the sides, roof and floor, displaying the remains of animals. The rock itself is thickly beset with teeth and bones, and the floor is covered with a loose earth, the evident result of animal decomposition, and in which numerous bones are imbedded.

A gradual descent leads to another grotto, which, with its passage, is forty feet in length, and twenty feet in hight. Its sides and top are beautifully adorned with stalactites. Nearly twenty feet further is a frightful gulf, the opening of which is about fifteen feet in diameter; and, upon descending about twenty feet, another grotto, about the same diameter with the former, but forty feet in hight, is seen. Here the bones are dispersed about; and the floor, which is formed of animal earth, has great numbers of them imbedded in it. The bones which are here found, seem to be of different animals; but in this, as well as in the former caverns, perfect and unbroken bones are very seldom found. Sometimes a tooth is seen projecting from the solid rock, through the stalactitic covering, showing that many of these wonderful remains may here be concealed. A specimen of this kind has been preserved, and is rendered particularly interesting, by the first molar tooth of the lower jaw, with its enamel quite perfect, rising through the stalactitic mass which invests the bone. In this cavern the stalactites begin to be of a larger size, and of a more columnar form.

Passing on through a narrow opening in the rock, a small cave, seven feet long, and five feet high, is discovered; another narrow opening leads to another small cave; from which a sloping descent leads to a cave twenty-five feet in hight, and about half as much in its diameter, in which is a truncated columnar stalactite, eight feet in circumference.

A narrow and most difficult passage, twenty feet in length, leads from this cavern to another, twenty-five feet in hight, which is everywhere beset with teeth, bones and stalactitic projections. This cavern is suddenly contracted, so as to form a vestibule of six feet wide, ten long, and nine high, terminating in an opening close to the floor, only three feet wide and two high, through which it is necessary to writhe, with the body on the ground. This leads into a small cave, eight feet high and wide, which is the passage into a grotto, twenty-eight feet high, and about forty-three feet long and wide. Here the prodigious quantity of animal earth, the vast number of teeth, jaws and other bones, and the heavy grouping of the stalactites, produce so dismal an appearance, as to become

a perfect model of a temple for a god of the dead. Here hundreds of cart-loads of bony remains might be removed, pockets might be filled with fossil teeth, and animal earth was found to reach to the utmost depth to which the workmen dug. A piece of stalactite, being here broken down, was found to contain pieces of bones within it, the remnants of which were left imbedded in the rock. From this principal cave is a very narrow passage, terminating in the last cave, which is about six feet in width, fifteen in hight, and the same in length. In this cave were no animal remains, and the floor was the naked rock.

Thus far only can these natural sepulchers be traced; but there is every reason to suppose, that these animal remains are disposed through a greater part of this rock. Whence this immense quantity of the remains of carnivorous animals could have been collected, is a question which naturally arises; but the difficulty of answering it appears to be almost insurmountable.

[Illustration: THE MAMMOTH CAVE.]

THE MAMMOTH CAVE.

For one of the earliest accounts of this stupendous cavern, which is unparalleled in the entire history of subterranean wonders, we are indebted to Dr. Nahum Ward, who published it in a monthly magazine, in October, 1816. It is in what was formerly Warren, but now Edmonson county, in the state of Kentucky, about ten miles from the great Louisville and Nashville turnpike. The territory is not mountainous but broken, differing in this respect from the vicinity of most other caverns of the same general kind. Not far from the entrance, a hotel is now kept for the accommodation of visitors, as the cave is quite a fashionable resort for travelers during the summer season. Perhaps we shall best gain correct ideas of this wonderful cavern, which is almost a world in itself, having its own seas, mountains, lakes, rivers, &c., by reading first the account given by Dr. Ward, and then that of a visitor who explored it in 1854.

Dr. Ward, provided with guides, two large lamps, a compass and refreshments, descended a pit forty feet in depth, and one hundred and twenty in circumference; having a spring of fine water at the bottom, and conducting to the entrance of the cavern. The opening, which is to the north, is from forty to fifty feet high, and about thirty in width. It narrows shortly after, but again expands to a width of thirty or forty feet, and a hight of twenty, continuing these dimensions for about a mile, to the first _hoppers_,[2] where a manufactory of saltpeter had recently been established. Thence to the second of these hoppers, two miles from the entrance, it is forty feet in width, and sixty in hight. Throughout nearly the whole of the distance handsome walls had been made by the manufacturers, of the loose limestone. The road was hard, and as smooth as a flag pavement. In every passage which the doctor traversed, the sides of the cavern were perpendicular, and the arches, which have bid defiance even to earthquakes, were regular. In 1802, when the heavy shocks of earthquakes came on which were so severely felt in this part of Kentucky, the workmen stationed at the second hoppers, heard about five minutes before each shock, a heavy rumbling noise issue from the cave, like a strong wind. When that ceased, the rocks cracked, and the whole appeared to be going in a moment to final destruction. However, no one was injured, although large portions of rock fell in different parts of the cavern.

Footnote 2:

A hopper is an inverted cone, into which corn is put at a mill before it runs between the stones.

In advancing into the cavern, the avenue leads from the second hoppers, west, one mile; and thence, south-west, to the chief area or city, which is six miles from the entrance. This avenue, throughout its whole extent from the above station to the cross-roads, or chief area, is from sixty to one hundred feet in hight, of a similar width, and nearly on a level, the floor or bottom being covered with loose limestone and saltpeter earth. “When,” observes the doctor, “I reached this immense area (called the chief city) which contains upward of eight acres, without a single pillar to support the arch, which is entire over the whole, I was struck dumb with astonishment. Nothing can be more sublime and grand than this place, of which but a faint idea can be conveyed, covered with one solid arch at least one hundred feet high, and to all appearance entire.”

Having entered the area, the doctor perceived five large avenues leading from it, from sixty to one hundred feet in width, and about forty in hight. The stone walls are arched, and were from forty to eighty feet perpendicular in hight before the commencement of the arch.

In exploring these avenues, the precaution was taken to cut arrows, pointing to the mouth of the cave, on the stones beneath the feet, to prevent any difficulty in the return. The first which was traversed, took a southerly direction for more than two miles; when a

second was taken, which led first east, and then north, for more than two miles further. These windings at length brought the party, by another avenue, to the chief city again, after having traversed different avenues for more than five miles. Having reposed for a few moments on slabs of limestone near the center of this gloomy area, and refreshed themselves and trimmed their lamps, they departed a second time, through an avenue almost north, parallel with the one leading from the chief city to the mouth of the cavern; and, having proceeded upward of two miles, came to the second city. This is covered with a single arch, nearly two hundred feet high in the center, and is very similar to the chief city, except in the number of its avenues, which are two only. They crossed it, over a very considerable rise in the center, and descended through an avenue which bore to the east, to the distance of nearly a mile, when they came to a third area, or city, about one hundred feet square, and fifty in hight, which had a pure and delightful stream of water issuing from the side of a wall about thirty feet high, and which fell on a broken surface of stone, and was afterward entirely lost to view.

Having passed a few yards beyond this beautiful sheet of water, so as to reach the end of the avenue, the party returned about one hundred yards, and passing over a considerable mass of stone, entered another, but smaller avenue to the right, which carried them south, through a third, of an uncommonly black hue, somewhat more than a mile; when they ascended a very steep hill about sixty yards, which conducted them to within the walls of the fourth city. It is not inferior to the second, having an arch which covers at least six acres. In this last avenue, the extremity of which can not be less than four miles from the chief city, and ten from the mouth of the cavern, are upward of twenty large piles of saltpeter earth on the one side, and broken limestone heaped up on the other, evidently the work of human hands.

From the course of his needle, the doctor expected that this avenue would have led circuitously to the chief city; but was much disappointed when he reached the extremity, a few hundred yards' distance from the fourth city. In retracing his steps, not having paid a due attention to mark the entrances of the different avenues, he was greatly bewildered, and once completely lost himself for nearly fifteen or twenty minutes. Thus, faint and wearied, he did not reach the chief area till ten at night; but was still determined to explore the cavern so long as his light should last. Having entered the fifth and last avenue from the chief area, and proceeded south-east about nine hundred yards, he came to the fifth area, the arch of which covers upward of four acres of level ground, strewed with limestone, and having fire-beds of an uncommon size, surrounded with brands of cane, interspersed. Another avenue on the opposite side, led to one of still greater capacity, the walls or sides of which were more perfect than any that had been noticed, running almost due south for nearly a mile and a half, and being very level and straight, with an elegant arch. While the doctor was employed, at the extremity of this avenue, in sketching a plan of the cave, one of his guides, who had strayed to a distance, called on him to follow. Leaving the other guide, he was led to a vertical passage, which opened into a chamber at least eighteen hundred feet in circumference, and the center of the arch of which was one hundred and fifty feet in hight.

It was past midnight when he entered this chamber of eternal darkness; and when he reflected on the different avenues through which he had passed since he had penetrated the cave at eight in the morning, and now found himself buried several miles in the dark recesses of this awful cavern—the grave, perhaps, of thousands of human beings—he felt a shivering horror. The avenue, or passage, which led from it was as large as any he had entered; and it is uncertain how far he might have traveled had his lights not failed him. All those who have any knowledge of this cave, he observes, conjecture that Green river, a stream navigable several hundred miles, passes over three of its branches.

After a lapse of nearly an hour, he descended by what is called the "passage of the chimney," and joined the other guide. Thence returning to the chief area or city, where the lamps were trimmed for the last time, he entered the spacious avenue which led to the second hoppers. Here he met with various curiosities, such as spars, petrifactions, &c.; and these he brought away, together with _a mummy_ which was found at the second hoppers. He reached the mouth of the cave about three in the morning, nearly exhausted with nineteen hours of constant fatigue. He nearly fainted on leaving it, and on inhaling the vapid air of the atmosphere, after having so long breathed the pure air occasioned by the niter of the cave. His pulse beat stronger when in the cave, but not so quick as when on the surface.

Here the doctor observes that he has hardly described half the cave, not having named the avenues between its mouth and the second hoppers. This part of his narrative is of equal interest with what has been already given. He states that there is a passage in the main avenue, upward of nine hundred feet from the entrance, like that of a trap-door. By sliding aside a large flat stone, you can descend sixteen or eighteen feet in a very narrow defile, where the passage comes on a level, and winds about in such a manner, as to pass under the main passage without having any communication with it, at length opening into the main cave by two large passages just beyond the second hoppers. This is called the "glauber-salt room," from salts of that kind being found there. Next come the sick room, the bat-room, and the flint-room, together with a winding avenue, which, branching off at the second hoppers,

runs west and south-west for more than two miles. It is called the “haunted chamber,” from the echo within: its arch is very beautifully incrusted with limestone spar; and in many places the columns of spar are truly elegant, extending from the ceiling to the floor. Near the center of this arch is a dome, apparently fifty feet high, hung in rich drapery, festooned in the most fanciful manner for six or eight feet from the hangings, and in colors the most rich and brilliant. By the reflection of one or two lights, the columns of spar and the stalactites have a very romantic appearance. Of this spar, a large elevation, called “Wilkin’s arm-chair,” has been formed in the center of the avenue and encircled with many smaller ones. The columns of the spar, fluted and studded with knobs of spar and stalactites; the drapery of the various colors superbly festooned and hung in the most graceful manner, these are shown with the greatest brilliancy by the reflection of the lamps.

In the vicinity of the haunted chamber, the sound of a cataract was heard; and at the extremity of the avenue was a reservoir of water, very clear and grateful to the taste, having, apparently, neither inlet nor outlet. Here the air, as in many other parts of the cave, was pure and delightful. Not far from the reservoir, an avenue presented itself, within which were several columns of the most brilliant spar, sixty or seventy feet in hight, and almost perpendicular, standing in basins of water; which, as well as the columns, were of surpassing splendor and beauty.

So far we have followed the brief and general account of Dr. Ward. Turning now to other accounts, we find that the cave extends for miles under the earth, and that the end of it has never yet been reached by any explorer. The air is not only pure, but delightful and exhilarating, and has been highly recommended for diseases of the lungs, so much so, that quite a number of small houses have been built within to accommodate consumptive persons, who at times have resided there with benefit. The temperature there is uniformly the same, being in both winter and summer, from fifty-five degrees to fifty-nine degrees Fahrenheit. Combustion is perfect in all parts of the cave, and decomposition is nowhere observable. No reptiles, of any description, have ever been seen within it. The loudest thunder can not be heard a quarter of a mile within, and the only sound is the roar of the waterfalls, of which there are some seven or eight.

The entire cave, so far as explored, contains two hundred and fifty or more avenues, nearly fifty domes, twenty-two pits and three rivers. Many of the avenues contain large and magnificent stalagmite columns, extending from the floor to the ceiling, and some of very grotesque and fanciful shape. Graceful stalactites may likewise be seen pendant from the ceilings, as uniform and regular as if they were cut by the hand of man. The engraving gives a view of one of those avenues where the stalagmites and stalactites abound in great profusion. In another part of this avenue, in what is called the Gothic Chapel, these stalactic formations are still more striking, very much resembling a monkish cathedral. In the Fairy Grotto, the formations likewise assume a great many fanciful shapes.

Passing now to the second account of a visit to the cave, to which we have already alluded, we find the visitor saying, that the cave is every way so wonderful, that it is impossible to give more than a faint idea of its magnificence and splendor. “As in exploring the cave,” he continues, “there are three rivers to cross and a great deal of climbing over rocks and crawling through narrow places, ladies adopt the Bloomer costume from necessity, and gentlemen are provided with dresses according to their fancy, so that a party starting out for a trip through the cave, present a most grotesque and comical appearance. On arriving at the mouth, the visitor is provided with a lamp, and makes an abrupt, though comparatively easy descent of some seventy or eighty feet. Here he enters a dark avenue, about five rods wide, called the Narrows, and soon finds himself far beyond where daylight ever shone. At the distance of about six hundred yards from the mouth, this avenue expands and forms a large circular room, called the Rotunda, or Great Vestibule. The guide stops here, and ignites a light, a compound of sulphur, saltpeter and antimony, prepared for illuminating the various points of special interest through the cave. This forms a most brilliant light, and reveals a room some two or three hundred feet wide, and forty-seven feet high. The view revealed by this first illumination is most imposing and sublime. I told my guide that he was certainly right in his ideas about describing the cave. As he saw me getting my paper and pencil ready at the mouth, he began laughing very significantly, and said, ‘Writin ’bout the cave aint no use, sir. Most everybody that goes in writes, but they gin’ally throws it away when they comes out. Writin don’t do no good. If anybody wants to know ’bout the cave, they must come and see it.’ Although I had barely commenced my journey through it, I told my guide that I could heartily subscribe to the whole of his speech on this subject.

“And right here, in the great vestibule, I will stop to say a few words about my guide. There are four guides to the cave, all of whom are said to be entirely familiar with it, and to give the most perfect satisfaction to visitors. At all events, I was entirely satisfied with ‘Alfred,’ with whom I made four different journeys through the cave, traveling under ground through various avenues more than fifty miles. Alfred formerly belonged to Miss Mary Croghan, whose elopement from a boarding-school on Staten Island about a dozen years ago, with Captain Shinley, created so great a sensation in New York and elsewhere. After she went to England, she gave

Alfred to some of her relatives, and he belonged to Dr. Croghan at the time of his death, who was the owner of the cave. By the terms of Dr. Croghan's will, Alfred and his wife and children will be free in about eighteen months. He is now drawing wages for his services, which, with the liberal presents he receives from visitors, will enable him to make a very fine start in the world. Alfred has evidently been a great pet, as he learned to read when very small; and he astonishes visitors by his use of scientific terms, and his knowledge of chemistry and geology. He has now been a guide to the cave about sixteen years; has visited it with a great many scientific men; has most of the standard works on geology, and is altogether an interesting character. He sees persons from all parts of the union, and understands all the excitements at the north, from that created by Uncle Tom's Cabin, down to the Forrest divorce trial. He was anxious to buy Uncle Tom's Cabin, and was told that he had better buy a Bible. So he paid four dollars and a half for a Bible, and bought Uncle Tom too. I can not do less than recommend all my friends who may visit the cave, to try and secure Alfred for a guide.

"Leaving the vestibule and passing the Kentucky cliffs, so called from their likeness to the cliffs in Kentucky river, we come to what is very appropriately named the Church and Galleries. At various points upon the route thus far, we have seen the leaching vats and other remains of the saltpeter works that were erected in the cave nearly fifty years ago. The manufacture of saltpeter was carried on quite extensively in the cave for several years, and the guide says the saltpeter was manufactured here with which the powder was made which was used in the battle of New Orleans. There is a very plain cart-path through this part of the cave, and we saw the tracks of oxen which were made forty-seven years ago. The church is the point in the cave where the miners assembled for worship. The rude pulpit or stand from which the preacher addressed his congregation, still remains. But besides this there is a natural pulpit and galleries which are easily ascended by steps in the wall, from which sermons are now frequently preached to visitors, for whom seats are provided. When illuminated, this church is more awfully imposing and solemn, than any temple built by human hands. The cave is more than one hundred feet wide, its massive rocky walls about fifteen feet high, and stretching away in each direction until lost in the most impenetrable darkness. For myself, I could not understand how any man would consent to lift his puny voice where God speaks so impressively. But there is a difference in tastes, and many, I doubt not, are persuaded against their own will to gratify the strong desire of the visitors to hear preaching in the cave. Going on from this point we pass the Grand Arch, a natural arch sixty-six feet high, and about seventy yards wide, and one hundred and fifty yards long; and some distance beyond are shown the Giant's Coffin. This is a huge rock, so formed that the top of it is a fine representation of a coffin. The shape is almost precisely that of a modern metallic coffin. This rock lies exactly east and west, by the compass, and is fifty-seven and a half feet long.

"Here we left the broad main cave in which we had thus far been traveling, and which stretched on indefinitely before us, and turned off into a narrow, circuitous, irregular avenue, and wandered indefinitely. Clambering over rocks, going down precipitous steeps, passing a great variety of rooms, lofty domes, intricate labyrinths, pits from seventy-five to one hundred and seventy-five feet deep, and a great many other points, all appropriately and often very significantly named, we at length came to Gorin's Dome, so called from the name of its discoverer, by far the most imposing I had yet seen. Coming to the end of a narrow avenue, the guide directed me to look through an opening in the wall, a kind of window, and our lamps revealed hights above and depths below, that seemed interminable! He then kindled one of the lights that I have already described, and placing it upon a board, thrust it through the opening and told me to look, first below and then above. The view was utterly indescribable and almost overpowering. The opening was not more than thirty feet in circumference, and I have already forgotten the hight and depth as given me by the guide. But I felt for hours and still feel the tremblings of those emotions that thrilled through my whole frame as I peered into those abysmal depths, and looked up into those giddy hights. None but Jehovah could build such a dome.

"I can not undertake to give the details of our route from avenue to avenue, nor mention the various points of interest that we passed. We were at length in a vast open space; the guide took our lamps, and going a short distance from us, told us to look up, and we at once discovered that we were in the far-famed Star Chamber. The cave here is some twenty or thirty yards wide, and about sixty or seventy feet high, and in a dim light the arch above presents the appearance of the sky in a very starry night. On looking up you see innumerable stars, and as you gaze for a long time the sky seems to be very distant, the stars increase in number, and it seems quite as if you were really looking through an opening in the cave into the heavens. Our guide Alfred was with Professor Silliman when he examined this arch by the aid of a Drummond light, to discover the cause of this appearance, and found that it was crystals embedded in the wall. After we had satisfied ourselves with viewing this artificial sky, Alfred took all our lamps and going into a cave below us, by the shadows from his lamps gave us a representation of clouds passing over the sky, obscuring the stars, thunder-clouds rolling over and the stars appearing again, and other interesting illusions. After this he went still deeper in the cave below us, leaving us in the most pitchy darkness. We were so deep in the bowels of the earth that the loudest thunder has never been heard there, and the silence and darkness were awfully impressive. Suddenly we saw in the direction in

which our guide had disappeared, a light like the rising of the moon, which grew larger and larger, until Alfred emerged through some opening from the regions below, and appeared in the distance in the same cave in which we were standing.

“After leaving this chamber, which was more beautiful than any we had entered, we made our way to the Gothic Gallery. This avenue was unlike anything we had yet seen. It is some four or five rods wide and three-quarters of a mile long, the path over which we walked being much more level than the most of those we had walked over, and much of the wall over our heads looking almost as smooth as if it had been plastered. In this avenue we visited the Haunted Chamber, so called from the fact that two mummies were discovered here many years ago; Vulcan’s Forge, so called from being very dark, and a formation resembling cinders; and near its end the Gothic Gallery. This room has a great variety of stalactite and stalagmite formations, many of which have formed solid massive pillars. As we approached the Chapel, our guide made us all stay behind, while he went ahead, taking all our lamps with him; and when we went forward at his call, we found each of our lamps hung upon some one of these pillars, and illuminating a room, compared with which Taylor’s saloon on Broadway, or the most gorgeous saloon New York can boast, is simplicity itself. These formations are a wonderful curiosity. They are of a very light color, are nearly as hard as granite, and are said to be formed by the drippings of lime water. They are in a great variety of shapes, to which a great many fanciful names have been given, such as the Pulpit, the Devil’s Arm-Chair, the Pillars of Hercules, &c.

“I had intended in this letter to speak of the chief points of interest in what is called the short route through the cave; that is, the portion of the cave that is visited without crossing either of the rivers. I made two visits on this side of the rivers, the first time traveling about six miles, and the second time traveling ten miles and a half. But I am the more willing to pass by the Bandit’s Hall, Mammoth Dome, Persico Avenue, Crockett’s Dome, Snowball Arch, Bunyan’s Way, and other places of special interest, with a mere mention of their names, from the fact that it is so entirely impossible to describe them. Some of these are but rarely visited, and it costs no little effort to reach them. But however narrow the fissures in the rocks through which we squeezed, however steep and slippery the ascent, however long the distance we had to crawl on our hands and knees, we were always more than paid for our pains.

“Omitting, then, any detailed account of what is called the short route, I pass to a notice of the long route, to which most of our time was given. In taking this we entered the cave as before, passed through the great vestibule, and on for a mile or two through the main branch, over the same route we had already traveled. It seems impossible to realize that this is a cave, it is so high, so wide, so vast. Several of our company remarked this fact. We seemed rather to be in some deep, dark ravine or mountain gorge, wandering by the light of our dim lamps, in some night that was utterly rayless and starless. We at length reached the Bottomless Pit, where we entered upon a path that was new to us. This pit is a deep, dark, fearful chasm, and received its name before anything like bottom had been found. It has now been measured to the depth of one hundred and seventy-five feet, and there may be fissures in the rock descending indefinitely below. Near this pit, we passed over an artificial bridge, and entered the Valley of Humility, through which we made our way, stooping and crawling, until we reached what is the most comical and laughable point in the cave, which is most appropriately named the Winding Way, or Fat Man’s Misery. This is an exceedingly circuitous opening in the rock, about eighteen inches wide, and between three and four hundred feet long. At the entrance of this way, the fissure through which we pass is not more than about two feet deep, and the ceiling above us is so high that we could stand erect without difficulty; but in advancing, the fissure becomes deeper, the rocks on either hand are higher and higher, and the ceiling above becomes lower and lower, and it seems to be, indeed, not only fat, but tall men’s misery. It is a most laughable sight to see a party edging their way through this zigzag path; a path that gives every indication of having been washed and worn by the action of the water for innumerable years. Our party was a decidedly lean one, so that we did not, like many others, have the amusement of seeing some one of aldermanic proportions squeeze and worry his way through. Finally, however, we got through, and came into a large open space, which our guide called Great Relief, and a _relief_ it was, sure enough. Passing on, we entered a large, roomy avenue called River Hall, where we were shown the high-water mark in the cave; where, in times of freshets, the river rises fifty-seven feet, perpendicularly, above low-water mark in the cave. We turned aside from this hall into a large room, to witness a great curiosity called the Bacon Chamber. Here the formations overhead are such as to make the room look remarkably like a large smoke-house filled with hams; and near by we were shown a smooth circular excavation in the wall above us, which was pointed out as the _kettle_ for boiling these hams, now turned bottom upward. Returning to the Hall, we went forward, passing several points of interest, until we came to a pure and beautiful body of water called Lake Lethe, upon which we embarked in a small boat provided for the purpose. We were now all on the look-out for the eyeless fish that are found in the waters of the cave, and were so fortunate as to catch in a small net, first, what was called a clawfish, having legs like a lobster, but eyeless and apparently bloodless, being almost precisely the color of potato sprouts that have grown in the spring in a dark cellar. Afterward we caught a very small fish of the same color, and having no eyes. Where the eyes should grow, the flesh was smooth and just like the rest of

the body. Whatever our doubts might have been before, we here had ocular demonstration that the fish in these waters, which are never illumined except by lamplight, are entirely without sight.

“Leaving Lake Lethe, we entered a most grand and imposing avenue, with lofty rocky walls towering about two hundred and fifty feet high, called the Great Walk. This leads to the Echo River, one of the greatest of these subterranean wonders. We sailed down this river a distance of _three-quarters of a mile_, and such a sail! Where on the earth or under the earth, could another such a sail be taken? The water was cold, clear and pure, and in color remarkably like the Niagara, as it plunges over the falls. At many places we could see the bottom, and in others it seemed of very great depth. It flowed in placid stillness, unrippled by a single breeze, between, above and beneath walls of massive and eternal rock. Now the channel was deep, narrow and tortuous, and now it spread out into a broad, pellucid stream. Now the massive ceiling above us was high, and smooth, and beautifully arched; and now it was so rough, broken and low, that we had to stoop as we sat in our boat, in order to pass under it. We did not pass rapidly down this stream. None of us were in a hurry. We seemed scarcely to belong to this driving, go-ahead world. Now a shout echoed wildly and magnificently through the rocky chambers; and now we sat entranced while one of our company, a splendid musician, sang some beautiful song, never as beautiful as now, when it echoed and reëchoed along these walls, and died away in the darkness that our dim lamps could not penetrate. This river, too, is most appropriately named. The echoes are most perfect and beautiful. We experimented in a great variety of ways, singing alone and in concert, shouting, whistling, clapping our hands, and finally, the whole company sung Ortonville. But there was one thing more impressive than all these, and that was silence! We sat in our boat as quietly as possible, no one speaking or moving for some time; and the stillness and the darkness by which we were surrounded, were solemn and awful beyond all description. We were deep in the bowels of the earth, I know not how many feet below its surface, but so low that no ray of light from the sun had ever penetrated its depths, and no voice of loudest thunder had ever waked an echo there. The silence was perfect, save the sound of breathing which each one tried to suppress, and the throbbing of our hearts that

‘Still like muffled drums were beating, Funeral marches to the grave.’

“God spoke in that stillness with a voice such as I had never heard before. I had never before so realized how awfully impressive were darkness and silence. I had entirely new ideas of the awful solitude of that period when the ‘earth was without form and void, and darkness was upon the face of the deep.’

“On getting beyond this river, we entered a region of avenues of incredible if not of interminable length, which have been discovered within the last twelve or fifteen years. One of the first of these is called Silliman Avenue, in honor of Professor Silliman, who has made very thorough explorations of the cave. This avenue is a mile and a half long, about three rods wide, and has various interesting features which I have not time to notice. At the termination of this avenue, the cave widens into a large room, several rods wide, and some fifty or sixty feet high, which is called Ole Bull’s concert-room, from the fact that this musician gave a free concert there to the visitors who were at the cave at the time of his visit.

“Beyond this room, we entered an avenue two miles long, called the Pass of El Gor. This is an exceedingly rocky and uneven avenue, leading, by a most circuitous path up and down great piles of rock, along a most rugged and desolate way, near deep holes and fissures in the rocks, until at length we come to a fine sulphur spring called Hebe’s Spring, which we found very refreshing. Here, through a narrow opening in the rocks, we climb a ladder eighteen feet high, and find a scene that abundantly compensates for the rough walk we have taken to reach it. On reaching the top of this ladder, we find ourselves in Martha’s Vineyard. Here is a vast room, the sides of which are covered over with a formation resembling grapes. They hang on the wall above, plump, round and perfect in form, and in the greatest profusion. They are so solid and hard that it is difficult to break off any of the clusters, and are said to be formed by the drippings of the water through the rocks. Near the head of the ladder there is a fine representation of a vine, of solid rock, running along the wall; and apparently connected with this vine, there are seemingly cart-loads of these rocky grapes. Our guide illumined the vineyard with one of his Bengal lights, and the view was magnificent.

“Going on from this point through Elindo’s Avenue and Washington’s Hall, we reached another of the remarkable rooms of the cave, called the Snowball Room. The cave is here about a hundred feet wide, ten or fifteen feet high, and the ceiling quite even and beautifully arched. Nature has here played most fantastic tricks. I know of no way so good to describe this room, as to say that its walls and ceiling overhead look like the end of some building that a score of school-boys have completely covered over with snowballs. We examined these formations for some time with our lamps, and then Alfred gave us the benefit of an illumination. But of its appearance when thus lighted up, I will attempt no description.

“We were now about seven miles from the mouth of the cave; and with appetites sharpened by our long walk, we sat down to the dinner which our host had sent along for us. It was a magnificent dining-saloon in which we were seated. Taylor’s saloon on Broadway is splendid, and has dazzled and bewildered multitudes, when they first entered it; but neither Taylor, nor prince, nor potentate, ever built a room so gorgeous as that in which we were seated. None but the God who built the skies, and bent and decorated the arch above us, could build another comparable to it.

“The Snowball Room is at the entrance of an avenue more extensive and beautiful than any other in the cave. This is called Cleveland’s Cabinet, and is altogether indescribable. It is about five rods wide and two miles long! Think of its dimensions a moment! About as long as Broadway from the Battery to Union Square, and with walls, not of brick, granite and marble, shaped and graven by art and man’s device, but with walls and ceiling above covered all over with the exquisite and beautiful workmanship of its divine builder.

“We passed slowly through this cabinet, two miles long, the guide conducting us from point to point of remarkable interest, and all the way along showing us new and strange developments. We went to Mary’s Bower, Virginia’s Festoons, Saint Cecelia’s Grotto, Flora’s Garden, where were roses and lilies, rosettes and wreaths, as perfect as though they had been chiseled there by the most accomplished sculptor. The formation on the wall in which these various flowers and other beautiful things are developed, is gypsum of the most snowy whiteness; and our guide said it was in three separate layers, and that the forming process was constantly going on, the inner layers crowding off the outer. The floor was covered with tuns of these layers, which had been crowded off, and which visitors are at liberty to carry off as specimens, while they are strictly prohibited from breaking anything from the walls. But still it is with the utmost difficulty that the guides can preserve some of the most beautiful views in the cave from the destruction of vandal visitors. This part of the cave is less beautiful than formerly, having become a good deal smoked by the lamps of the thousands of visitors who have examined it. But our guide took us into an avenue immediately under this, which is but rarely visited, and conducted us to a most enchanting spot called Egeria’s Grotto. Here the formations were as pure, and beautiful and white, as if fresh from the hand of their Maker. Here were formations, not only of the purest white, but of other most exquisite coloring. We remained a long time in this grotto, examining its various wonders, and deemed ourselves very fortunate in seeing it, as from this we could better understand how Cleveland’s Cabinet above us appeared during the long ages that intervened before it was polluted by the presence of man. Another beautiful grotto was perfectly brilliant and gorgeous, and looked as though its rough walls were a solid mass of diamonds. The most gorgeous and brilliant room ever built in the palace of an earthly monarch, is tameness itself compared with this diamond grotto.

“Emerging again into Cleveland’s Cabinet, we passed on to its termination, where we ascended the Rocky Mountains, a vast pile of loose, broken rocks, one hundred and sixty feet high, which have apparently dropped down from the cave above, leaving a vast vaulted opening in the cave above, to indicate the place from which they have fallen. Beyond these mountains, the cave branches in three directions. We took the branch leading to Croghan’s Hall, the remotest point in the cave that has yet been visited, and _nine miles from its mouth_. On the right of this room there is a deep, awful pit, into which we threw stones, as we had into many others, and heard them roll and bound from rock to rock, down a distance of one hundred and eighty-five feet. The water from some point below us runs over these rocks, and flows off, no mortal knows where. This hall contains large, massive pillars, elaborately carved and ornamented by the Invisible Architect, stalactites and stalagmites of various beautiful forms, and its walls are festooned with that rich drapery which no art can imitate, and which only decks the grottos, bowers and halls of this wonderful cave.

“After refreshing ourselves here from a pleasant spring, we started on our nine-mile tramp for the mouth of the cave, taking only a hurried glance of the varied objects of interest as we passed them. We, however, sailed very leisurely down Echo River, or the Jordan, as it is also called. We again had solos and choruses, and drank in rich delights from this enchanting sail. When we reached Lethe, some of our party determined to send their clothes across in our boat and swim over. They accordingly plunged in very boldly, but hurried out in the quickest time possible; and the chattering of teeth, shivering, leaping and running to get warm again, seemed more befitting a bath in February, than in one of the hottest days in August.

“I had now made four different visits to the cave, traveling, according to the reckoning of my guide, about fifty-four miles. Very few visitors explore it as thoroughly, and yet I had not gone over one-third of the space that has already been explored. The guide says that two hundred and fifty different avenues are already known, measuring the distance of one hundred and sixty-five miles. The temperature of the cave is uniformly about fifty-five degrees, and its bracing, invigorating character may be judged from the fact that ladies, some of them quite delicate, are constantly taking this ‘long route,’ traveling a greater number of miles than most men would think of going on foot above ground.

“We felt but little fatigue from our rough, clambering walk of some twenty miles, until we emerged from the cave, and came in contact with outer air. After breathing the air of the cave from eight A. M. till five P. M., the atmosphere seemed very impure. We could smell every tree, and plant, and old log; and the air was so sultry and sickening, that we had to rest awhile at the mouth before starting for the hotel, some fifty rods distant.

“I have thus attempted to redeem my promise in regard to writing you from the cave. I had no thought of writing at so great length. If the cave were possessed of mind and sensibility, I would take off my hat to it, and feelingly ask its pardon for the great injustice I have done it in these letters. But as it is, I will only say that I have over and over again assented to the truthfulness and justice of my guide Alfred’s idea of all descriptions of the cave: ‘Writin don’t do no good. If anybody wants to know how the cave looks, they must come and see it.’ And I can not conceive of any journey for this purpose so long and toilsome, that those making it would not be abundantly compensated for their pains, by a view of this wonderful work of a wonder-working God.”

Still another visitor, writing to a friend in Europe, says of this wonderful cave, “I had heard and read descriptions of it, long since; but the half, the quarter, was not told. Its vastness, its lofty arches, its immense reach into the bosom of the solid earth, fill me with astonishment. It is, like Mont Blanc, Chimborazo, and the falls of Niagara, one of God’s mightiest works. Shall I compare it with anything of a similar description, which you have seen on the other side of the Atlantic? with the grotto of Neptune, or that of the Sibyl, at Tivoli, or with any of Virgil’s poetic Italian machinery? No comparison can be instituted. I speak, as you are aware, from personal knowledge. You, seated on the opposite bank of the Arno, have seen me clamber up, from the noisy waters below, to the entrance of the far-famed grotto of Neptune, which I leisurely explored. In point of capaciousness, that grotto has little more to boast of than the cellar of a large hotel, and, like that, was, as I think, excavated by human hands. That of the Tiburtine Sibyl is still more limited in its dimensions. Indeed, every cavern which I have ever seen, if placed along side of this, would dwindle into insignificance.”

The same writer says, “I can not refrain from giving you an account of an incident that happened in this cave last spring. A wedding party went to the cave to spend the honeymoon. While there, they went to visit those beautiful portions of the cave which lie beyond the river ‘Jordan.’ In order to do this, a person has to sail down the river nearly a mile before reaching the avenue which leads off from the river on the opposite side, for there is no shore, or landing-place, between the point above on this side, where you come to the river, and that below on the other; for the river fills the whole width of one avenue of the cave, and is several feet deep where the side walls descend into the water. This party had descended the river, visited the cave beyond, and had again embarked on the water for their return homeward. After they had ascended the river about half-way, some of the party, who were in a high glee, got into a romp and overturned the boat. Their lights were all extinguished, their matches wet, the boat filled with water and sunk immediately; and _there they were_, in ‘the blackness of darkness,’ up to their chins in water. No doubt, they would all have been lost, had it not been for the guide’s great presence of mind. He charged them to remain perfectly still; for, if they moved a single step, they might get out of their depth in water; and swimming would not avail them, for they could not see where to swim to. He knew that, if they could bear the coldness of the water any length of time, they would be safe; for another guide would be sent from the cave house, to see what had become of them. And in this perilous condition, up to their mouths in water, in the midst of darkness ‘more than night,’ _four miles under ground_, they remained for upward of five hours; at the end of which time, another guide came to their relief. Matthew, or Mat, the guide who rescued them, told me that, when he got to where they were, his fellow-guide, Stephen, (the Columbus of the cave,) was swimming around the rest of the party, cheering them, and directing his movements, while swimming, by the sound of their voices, which were raised, one and all, in prayer and supplication for deliverance!”

In conclusion it may be interesting to state, that Colonel Croghan, to whose family the Mammoth cave belongs, was a resident of Louisville, Kentucky. He went to Europe some twenty years ago, and found himself frequently questioned of the wonders of the Mammoth cave, a place he had never visited, and of which he had heard but little at home, though living within ninety miles of it. He went there on his return, and the idea struck him to purchase it, and make it a family inheritance. In fifteen minutes’ bargaining he bought it for ten thousand dollars, and shortly after he was offered one hundred thousand dollars for his purchase. In his will he tied it up in such a way that it must remain in his family for two generations, thus appending its celebrity to his name. There are nineteen hundred acres in the estate, though the cave probably runs under the property of a great number of other land owners. For fear of those who might dig down and establish an entrance to the cave on their own property, (a man’s farm extending up to the zenith and down to the nadir,) great vigilance is exercised to prevent such subterranean surveys and measurements as would enable one to sink a shaft with any certainty. The cave extends ten or twelve miles in several directions, and there is probably many a back-woodsman sitting in his hut within ten miles of the cave, quite unconscious that the most fashionable ladies and gentlemen of

Europe and America are walking without leave under his potatoes and corn.

THE GREAT CAVERN OF GUACHARO.

Passing from the Mammoth cave in North America, let us next notice the great cavern of Guacharo in South America, as described in the narrative of Humboldt, which is abridged in the account that follows.

“In a country where the people are fond of the marvelous, a cavern that gives birth to a river, and which is inhabited by thousands of nocturnal birds, the fat of which is used to dress the food of the inhabitants, is a ceaseless topic of conversation and discussion. Scarcely has a stranger arrived at Cumana, when he is told of the stone of Araya for the eyes; of the laborer of Arenas who suckled his child; and of the cavern of Guacharo, which is said to be several leagues in length; till he is tired of hearing of them.

“The Cueva del Guacharo is pierced in the vertical profile of a rock. The entrance is toward the south, and forms a vault eighty feet broad, and seventy-two feet high. The rock, that surmounts the grotto, is covered with trees of gigantic hight. The mammee-tree, and the genipa with large and shining leaves, raise their branches vertically toward the sky; while those of the courbaril and the erythrina form, as they extend themselves, a thick vault of verdure. Plants of the family of pothos with succulent stems, oxalises, and orchideæ of a singular structure, rise in the driest cliffs of the rocks; while creeping plants, waving in the winds, are interwoven in festoons before the opening of the cavern. We distinguished in these festoons a bignonia of a violet blue, the purple dolichos, and for the first time that magnificent olandra, the orange flower of which has a fleshy tube more than four inches long. The entrances of grottos, like the view of cascades, derive their principal charm from the situation, more or less majestic, in which they are placed, and which in some sort determines the character of the landscape. What a contrast between the Cueva of Caripe, and those caverns of the north crowned with oaks and gloomy larch-trees!

“But this luxury of vegetation embellishes not only the outside of the vault, it appears even in the vestibule of the grotto. One sees with astonishment plantain-leaved heliconias eighteen feet high, the praga palm-tree, and arborescent arums, follow the banks of the river even to those subterranean places. The vegetation continues in the cave of Caripe, as in the deep crevices of the Andes, half excluded from the light of day; and does not disappear, till, advancing into the interior, we reach thirty or forty paces from the entrance. We measured the way by means of a cord; and we went on about four hundred and thirty feet, without being obliged to light our torches.

“Daylight penetrates into this region, because the grotto forms but one single channel, which keeps the same direction from south-east to north-west. Where the light begins to fail, are heard from afar the hoarse sounds of the nocturnal birds, sounds which the natives think belong exclusively to those subterraneous places. The guacharo is of the size of our fowls, has the mouth of the goatsuckers and procnias, and the port of those vultures, the crooked beak of which is surrounded with stiff silky hairs. It forms a new genus, very different from the goatsucker by the force of its voice, by the considerable strength of its beak, containing a double tooth, and by its feet without the membranes that unite the anterior phalanxes of the claws. In its manners it has analogies both to the goatsuckers and the alpine crow. The plumage of the guacharo is of a dark bluish-gray, mixed with small streaks and specks of black. It is difficult to form an idea of the horrible noise occasioned by thousands of these birds in the dark part of the cavern, and which can only be compared to the croaking of our crows, which, in the pine forests of the north, live in society, and construct their nests upon trees, the tops of which touch each other. The shrill and piercing cries of the guacharoes strike upon the vaults of the rocks, and are repeated by the echo in the depth of the cavern. The Indians showed us the nests of these birds, by fixing torches to the end of a long pole. These nests were fifty or sixty feet high above our heads, in holes in the shape of funnels, with which the roof of the grotto is pierced like a sieve. The noise increased as we advanced, and the birds were affrighted by the light of the torches of copal. When this noise ceased around us, we heard at a distance the plaintive cries of the birds roosting in other ramifications of the cavern. It seemed as if these bands answered each other alternately.

“The Indians enter into the Cueva del Guacharo once a year, near midsummer, armed with poles, by means of which they destroy the greater part of the nests. At this season several thousands of birds are killed; and the old ones, to defend their brood, hover around the heads of the savage Indians, uttering terrible cries, which would appall any heart but that of man in an untutored state.

“We followed, as we continued our progress through the cavern, the banks of the small river which issued from it, and is from twenty-eight to thirty feet wide. We walked on the banks, as far as the hills formed of calcareous incrustations permitted us. When the torrent wound among very high masses of stalactites, we were often obliged to descend into its bed, which is only two feet in depth. We learned with surprise, that this subterraneous rivulet is the origin of the river Caripe, which, at a few leagues’ distance, after having joined the small river of Santa Maria, is navigable for canoes. It enters into the river Areo under the name of Canno de

Terezen. We found on the banks of the subterraneous rivulet a great quantity of palm-tree wood, the remains of trunks, on which the Indians climb to reach the nests hanging to the roofs of the cavern. The rings, formed by the vestiges of the old footstalks of the leaves, furnish as it were the footsteps of a ladder perpendicularly placed.

“The grotto of Caripe preserves the same direction, the same breadth, and its primitive hight of sixty or seventy feet, to the distance of fourteen hundred and fifty-eight feet, accurately measured. I have never seen a cavern in either continent, of so uniform and regular a construction. We had great difficulty in persuading the Indians to pass beyond the outer part of the grotto, the only part which they annually visit to collect the fat. The whole authority of the priests was necessary, to induce them to advance as far as the spot where the soil rises abruptly at an inclination of sixty degrees, and where the torrent forms a small subterraneous cascade.[3] The natives connect mystic ideas with this cave, inhabited by nocturnal birds; they believe, that the souls of their ancestors sojourn in the deep recesses of the cavern. ‘Man,’ say they, ‘should avoid places which are enlightened neither by the sun nor by the moon.’ To go and join the guacharoes, is to rejoin their fathers, is to die. The magicians and the poisoners perform their nocturnal tricks at the entrance of the cavern, to conjure the chief of the evil spirits.

Footnote 3:

We find this phenomenon of a subterranean cascade, but on a much larger scale, in England, at Yordas cave, near Kingsdale, in Yorkshire.

“At the point where the river forms the subterraneous cascade, a hill covered with vegetation, which is opposite the opening of the grotto, presents itself in a very picturesque manner. It appears at the extremity of a straight passage, two hundred and forty toises in length. The stalactites, which descend from the vault, and which resemble columns suspended in the air, display themselves on a back-ground of verdure. The opening of the cavern appeared singularly contracted, when we saw it about the middle of the day, illumined by the vivid light reflected at once from the sky, the plants, and the rocks. The distant light of day formed somewhat of a magical contrast with the darkness that surrounded us in those vast caverns. We climbed, not without some difficulty, the small hill, whence the subterraneous rivulet descends. We saw that the grotto was perceptibly contracted, retaining only forty feet in its hight; and that it continued stretching to the northeast, without deviating from its primitive direction, which is parallel to that of the great valley of Caripe.

“The missionaries, with all their authority, could not prevail on the Indians to penetrate farther into the cavern. As the vault grew lower, the cries of the guacharoes became more shrill. We were obliged to yield to the pusillanimity of our guides, and trace back our steps. We followed the course of the torrent to go out of the cavern. Before our eyes were dazzled with the light of day, we saw without the grotto, the water of the river sparkling amid the foliage of the trees that concealed it. It was like a picture placed in the distance, and to which the mouth of the cavern served as a frame. Having at length reached the entrance, and seated ourselves on the bank of the rivulet, we rested after our fatigues. We were glad to be beyond the hoarse cries of the birds, and to leave a place where darkness does not offer even the charms of silence and tranquillity.”

FINGAL’S CAVE,

OR GRAND STAFFA CAVERN.

Staffa, about seven miles north-north-east of Jona, and equidistant westward from the shores of Mull, about one mile in length, and half a mile in breadth, is noted for the basaltic pillars which support the major part of the island, and for the magnificent spectacle afforded by the cave of Fingal, one of the most splendid works of nature.

Notwithstanding the contiguity of this wonderful island to Mull and Iona, and the numerous vessels which navigate these seas, it was unknown to the world in general, and even to most of the neighboring islanders, until near the close of the last century, when Sir Joseph Banks, then on his voyage to Iceland, in consequence of information received in the sound of Iona, from some gentlemen of Mull, was induced to sail thither. It is, indeed, slightly mentioned by Buchanan; but assuredly it was not equally dead to fame at the time the Norwegians had sway in these parts, for from them it derives its name of Staffa.

The basaltic pillars stand in natural colonnades, mostly above fifty feet high, in the south-western part, upon a firm basis of solid unshapen rock: above these, the stratum, which reaches to the soil of the island, varies in thickness, in proportion to the distribution

of the surface into hill and valley. The pillars are of three, four and more sides; but the number of those with five and six exceeds that of the others; one of seven sides measured by Sir Joseph, was four feet and five inches in diameter.

On the west side of Staffa is a small bay, the spot where boats usually land. In this neighborhood occurs the first group of pillars: they are small, and instead of being placed upright, are recumbent on their sides, and form a segment of a circle. Further on is a small cave, above which pillars again are seen, of somewhat larger dimensions, which incline in all directions; in one place in particular, a small mass of them much resembles the ribs of a ship. Beyond the cave is the first continued range of pillars, larger than the former, and opposite to them is a small island called Bhuachaile, (pronounced Boo-sha-'lay,) or the Herdsman's isle, separated from the main by a channel not many fathoms wide. The whole of this islet is composed of pillars without any strata above them; they are small, but by much the neatest formed of any in this quarter.

The first division of this islet, for at high tide it is divided into two parts, makes a kind of cone, the pillars converging together toward the center. On the other side the pillars are in general recumbent; and in the front, next the main, the beautiful manner in which they are joined is visible from their even extremities: all these have their transverse sections exact, and their surfaces smooth; but with the larger pillars the reverse is the case, and they are cracked in all directions.

The main island opposite the Boo-sha-'lay, and thence toward the north-west, is entirely supported by ranges of pillars, pretty erect, which, although not apparently tall, from their not being uncovered to the base, are of large diameter; at their feet is an irregular pavement, made by the upper sides of such as have been broken off. This extends as far under the water as the eye can reach.

In proceeding along the shore, the superb cavern of Fingal appears, for such is the denomination given it by the Highlanders, to whom it is known. It is supported on each side by ranges of columns, and is roofed by the bottoms of such as have been broken away. From the interstices of the roof a yellow stalactitic matter has exuded, which precisely defines the different angles; and, varying the color, tends to augment the elegance of its appearance. What adds to the grandeur of the scene, the whole cave is lighted from without, in such a manner, that the furthest extremity is plainly distinguished; while the air within, being constantly in motion, owing to the flux and reflux of the tides, is perfectly dry and wholesome, and entirely exempt from the damp vapors to which natural caverns are generally subject. The following are its dimensions:

Feet. In. Length of the cave from the rock without, 371 6 Length of the cave from the pitch of the arch, 250 0 Breadth of the cave at the mouth, 53 7 Breadth of the cave at the further end, 20 0 Hight of the arch at the mouth, 117 6 Hight of the arch at the end, 70 0 Hight of an outside pillar, 39 6 Hight of one at the north-west corner, 54 0 Depth of water at the mouth, 18 0 Depth of water at the extremity, 9 0

The cave runs to the rock in the direction, by compass, north-north-east.

The mind can hardly form an idea more magnificent than such a space. And, indeed, speaking of the general aspect of Staffa, Sir Joseph is led, by his enthusiasm, to make the following reflections: "Compared to this, what are the cathedrals or the palaces built by man! mere models or playthings, imitations as diminutive as his works will always be, when compared to those of Nature. Where is now the boast of the architect! regularity, the only part in which he fancied himself to exceed his mistress, Nature, is here found in her possession, and here it has been left undescribed for ages. Is not this the school where the art was originally studied? And what has been added to this by the whole Grecian school? A capital to ornament the column of Nature, of which they could execute a model only; and for that very capital they were obliged to a bush of acanthus. How amply does Nature repay those who study her wonderful works."

Such were his feelings, and in this way did he moralize, when proceeding along shore, and treading as it were on another Giant's Causeway, he arrived at the mouth of the cave.

To the north-west are found the highest range of pillars. Here they are bare to their base, and the stratum beneath is visible, as it rises several feet above the water. The surface of it is rough, with frequent large pieces of stone sticking in it, as if half immersed. The base, when broken, appears to be composed of many heterogenous parts, and much resembles lava. Many of the floating stones are of a similar substance with the pillars, a coarse kind of basalt, less beautiful than that of the Giant's Causeway: the color is a dirty brown. The whole of this stratum dips gradually to the south-east.

The thickness of the stratum of lava-like matter below the pillars, the hight of the pillars, and the thickness of the superincumbent stratum, at three different places westward of the mouth of the cave, beginning with the corner pillar of the cave, are described as follows by Sir Joseph Banks:

Feet. In. Feet. In. Feet. In. Stratum below, 11 0 17 1 19 8 Hight of pillars, 54 0 50 0 55 1 Stratum above, 61 6 51 1 54 7

The stratum above the columns is uniformly the same, consisting of numberless small pillars, bending and inclining in all directions, sometimes so irregularly, that the stones can only be said to have an inclination to assume a columnar form; in others more regularly; but never breaking into, or disturbing the stratum of large pillars, whose tops keep everywhere an uniform line. On the opposite side of the island is a cavern, called Oua-na-scarve, or the Cormorant's cave; here the stratum under the pillars is lifted up very high, and the pillars are considerably less than at the north-west side. Beyond, a bay cuts deep into the island, rendering it not more than a quarter of a mile across. On the sides of this bay, especially beyond a little valley, which almost divides the island, are two stages of small pillars, with a stratum between, exactly resembling that above, formed of innumerable little pillars shaken out of their places, and leaning in all directions. Beyond this, the pillars totally cease. The rock is of a dark-brown stone, without regularity, from the bay along the south-east end of the island; beyond which, a disposition to columnar formation is again manifested, extending from the west side, but in an irregular manner, to the bending pillars first described.

OTHER GROTTOS AND CAVERNS.

There are few countries which have not to boast of a variety of natural excavations; and these have, from their extent, structure, and the curious phenomena they exhibit, in the formation of petrifactions, &c., been at all times objects of popular attention. Among those particularly deserving of notice are the following.

The volcanic country bordering on Rome, is peculiarly diversified by natural cavities of great extent and coolness; on which last account it is related by Seneca, that the Romans were accustomed to erect seats in their vicinity, to enjoy their refreshing chillness in the summer season. He gives a particular account of two such grottos belonging to the villa of Vatia; and it was in a place of this kind that Tiberius was nearly destroyed while at supper. Its roof suddenly gave way, and buried several of his attendants in its ruins; which so alarmed the others, that they fled and abandoned the emperor, with the exception of Sejanus, who, stooping on his hands and knees, and covering the body of Tiberius with his own, received all the stones which fell at that part from the roof, insomuch that, although he himself sustained considerable injury, the emperor escaped unhurt.

The grottos of the Cevennes mountains, in lower Languedoc, are both numerous and extensive. The principal one is not to be explored without much precaution, and without a safe guide. The entrance, which is low and narrow, leads to a spacious amphitheater, the petrifactions hanging from the roof of which have a most splendid effect by the light of torches. Hence the visitor has to descend to several chambers, one of which is named the Chamber of the Winds; another, of Echo; another, of the Cascade; another, again, of the Statue, &c.; on account of their exhibiting these different phenomena. In the grotto of Valori, at a small distance, the different natural curiosities which are to be found at every step, may be viewed at leisure, and without apprehension, as the visitor never loses sight of the light at the entrance, and is, therefore, not under any dread of not returning in safety. Here he is gratified by a view of the most singular petrifactions, representing flowers, fruits, bee-hives, and, in short, a variety of objects, in many of which the resemblance is nearly as accurate as if they had been sculptured.

In a wood, about five leagues from Besançon, in the province of France called Franche Comte, an opening, formed by two masses of rock, leads to a cavern more than nine hundred feet beneath the level of the country. It is in width sixty feet, and eighty feet high at the entrance, and exhibits inside an oval cavity of one hundred and thirty-five feet in breadth, and one hundred and sixty-eight in length. To the right of the entrance is a deep and narrow opening, bordered with festoons of ice, which, distilling in successive drops on the bottom of the cavern, form a mass of about thirty feet in diameter. A similar one, but somewhat smaller, produced by the water which drips in less abundance from the imperceptible fissures in the roof, is seen on the left. The ground of the cavern is perfectly smooth, and covered with ice eighteen inches thick; but the top, on the outside, is a dry and stony soil, covered with trees, and on a level with the rest of the wood. The cold within this cavern is so great, that, however warm the external atmosphere may be when it is visited, it is impossible to remain in it for any length of time.

These natural ice-houses are not unfrequent in France and Italy, and supply this agreeable luxury at a very cheap rate. Thus, in the same province, in the vicinity of Vesoul, is a cavern which, in the hot season, when it is eagerly sought, produces more ice in one day, than can be carried away in eight. It measures thirty-five feet in length, and in width sixty. The large masses of ice which hang pendent from the roof, have a very pleasing effect. When mists are observed in this cavern, they are regarded by the neighboring peasantry as infallible prognostics of rain; and it is worthy of observation, that although the water in the interior is always frozen in the summer, it becomes liquid in the winter season.

A grotto near Douse, also in Franche Comte, forms a similar ice-house, and is remarkable on account of the various forms of its congelations, which represent a series of columns, sustaining a curious vault, which appears to be carved with figures of men, animals, trees, &c.

The caverns of Gibraltar are numerous, and several of them of great extent. The one more particularly deserving attention is called St. Michael's cave, situated on the southern part of the mountain. Its entrance is one thousand feet above the level of the sea, and is formed by a rapid slope of earth, which has fallen in at various periods, and which leads to a spacious hall, incrusted with spar, and apparently supported in the center by a large stalactitical pillar. To this succeeds a long series of caves, of difficult access. The passages leading from the one to the other are over precipices, which can not be passed without the aid of ropes and scaling-ladders. Several of these caves are three hundred feet beneath the upper one; but at this depth the smoke of the torches carried by the guides becomes so disagreeable, that the visitor is obliged reluctantly to give up the pursuit, and leave other caves unexplored. In these cavernous recesses, the process and formation of the stalactites is to be traced, from the flimsy quilt-like cone suspended from the roof, to the robust trunk of a pillar, three feet in diameter, which rises from the floor, and seems intended by nature to support the roof from which it originated.

The variety of forms which this matter takes in its different situations and directions, renders this subterraneous scenery strikingly grotesque, and in some places beautifully picturesque. The stalactites of these caves, when near the surface of the mountain, are of a brownish yellow color; but, in descending toward the lower caves, they lose the darkness of their color, which is by degrees shaded off to a pale yellow. Fragments are broken off, and, when wrought into different forms, and polished, are beautifully streaked and marbled.

About seven English miles from Adlersberg, in Carniola, is a remarkable cavern, named St. Magdalen's cave. The road being covered with stones and bushes, is very painful; but the great fatigue it occasions is overbalanced by the satisfaction of seeing so uncommon a cavern. The visitor first descends into a hole, where the earth appears to have fallen in for ten paces, when he reaches the entrance, which resembles a fissure caused by an earthquake, in a huge rock. The torches are here lighted, the cave being extremely dark. This wonderful natural excavation is divided into several large halls, and other apartments. The vast number of pillars by which it is ornamented give it a superb appearance, and are extremely beautiful: they are as white as snow, and have a semi-transparent luster. The bottom is of the same materials; insomuch that the visitor may fancy he is walking beneath the ruins of some stately palace, amid noble pillars and columns, partly mutilated, and partly entire. Sparry icicles are everywhere seen suspended from the roof, in some places resembling wax tapers, which, from their radiant whiteness, appear extremely beautiful. All the inconvenience here arises from the inequality of the surface, which may make the spectator stumble while he is contemplating the beauties above and around him.

In the neighborhood of the village of Szelitze, in Upper Hungary, there is a very singular excavation. The adjacent country is hilly, and abounds with woods, the air being cold and penetrating. The entrance into this cavern, fronting the south, is upward of one hundred feet in hight, and forty-eight in breadth, consequently sufficiently wide to receive the south wind, which here generally blows with great violence; but the subterraneous passages, which consist entirely of solid rock, winding round, stretch still farther to the south. As far as they have been explored, their hight has been found to be three hundred feet, and their breadth about one hundred and fifty. The most inexplicable singularity, however, is, that in the midst of winter the air in this cavern is warm; and when the heat of the sun without is scarcely supportable, the cold within is not only very piercing, but so intense, that the roof is covered with icicles of the size of a large cask, which, spreading into ramifications, form very grotesque figures. When the snow melts in spring, the inside of the cave, where its surface is exposed to the south sun, emits a pellucid water, which congeals instantly as it drops, and thus forms the above icicles: even the water which falls from them on the sandy ground, freezes in an instant. It is observed, that the greater the heat is without, the more intense is the cold within; so that, in the dog-days, every part of this cavern is covered with ice. In autumn, when the nights become cold, the ice begins to dissolve, insomuch that, when the winter sets in, it is no longer to be seen; the cavern then is perfectly dry, and has a mild and gentle warmth. It is, therefore, not surprising that swarms of flies, gnats, bats, owls, and even great numbers of foxes and hares, resort thither, as to their winter retreat, and remain there till the return of spring.

MINES, METALS, GEMS, &C.

"Through dark retreats pursue the winding ore, Search nature's depths, and view the boundless store; The secret cause in tuneful numbers sing, How metals first were framed, and whence they spring: Whether the active sun, with chymic flames, Through porous earth transmits his genial beams With heat impregnating the womb of night The offspring shines with his paternal light: Or whether,

urged by subterraneous flames, The earth ferments and flows in liquid streams; Purged from their dross, the nobler parts refine, Receive new forms, and with new beauty shine: Or whether by creation first they sprung, When yet unpoised the world's great fabric hung: Metals the bases of the earth were made, The bars on which its fixed foundation's laid: All second causes they disdain to own, And from the Almighty's fiat sprung alone."

The transition from the caverns and caves of the earth, to its MINES, and the various metals and gems they contain, is both natural and easy; and having dwelt on the former, we propose next to advert to the latter. By the word "_mines_" we understand those excavations, in which metals, minerals and precious stones are sought and found; and according to the substances which they yield they are variously spoken of as "gold mines," "silver mines," "lead mines," &c., &c. The richest and most celebrated gold and silver mines are those of Mexico and Peru, in South America, and those lately discovered in California and Australia. Iron mines are more abundant, or at least more abundantly worked, in Europe than elsewhere, though the rapid increase of iron mining in the United States gives promise that our country may in this respect some day rival the old world. Copper mines have been found chiefly in England, Sweden and Denmark; and of late years copper has been found to be abundant in the region of our northern lakes. Lead and tin mines are numerous in England, the latter chiefly in the county of Cornwall; and lead is also found in abundance in the United States. Quicksilver mines abound principally in Hungary, Spain, Friuli, in the Venetian territories, and in Peru. Diamond mines are mainly in Brazil, and some in the East Indies; and salt mines are in Poland.

To explain the structure of mines, it should be observed that the internal parts of the earth, as far as they have been investigated, do not consist of any one uniform substance, but of various strata, or beds of substances, extremely different in their appearances, specific gravities and chemical qualities, one from another. Neither are these strata similar to each other, either in their nature or appearance, in different countries; insomuch that, even in the short extent of half a mile, sometimes, the strata will be found quite different in one from what they are in another place. As little are they the same either in depth or solidity. Innumerable cracks and fissures are found in all of them; and these again are so entirely different in size and shape, that it is impossible to form any inference from what may have been met with, relative to that which remains to be explored.

In Cornwall, the most common opinion entertained by the miners, is, that crude and immature minerals nourish and feed the ores with which they are intermixed in the mines; and that the minerals themselves will, in process of time, be converted into ores productive of those metals to which they have the nearest affinity, and with which they are most closely intermingled. And a distinguished professor, who is familiar alike with geology, chemistry and mineralogy, after visiting the mining districts of California, has given it as his opinion, that gold is constantly being formed there, by some powerful agency of nature which is still and steadily at work. And as a somewhat kindred view, Mr. Price, in his mineralogy of Cornwall, thinks it is most reasonable to conclude, that metals were made and planted in veins, at, or very soon after, the creation of the world; but that, in common with all other matter, they are subject to a degree of fluctuation, approaching to, or receding from, their ultimate degree of perfection, either quicker or slower, as they are of greater or less solid and durable frame and constitution. He supposes in every metal a peculiar magnetism, and an approximation of particles of the same specific nature, by which its component principles are drawn and united together; more particularly the matters left by the decomposition of the waters passing through the contiguous earths or strata, and deposited in their proper nidus or receptacle, until, by the accretion of more or less of its homogeneous particles, the metallic vein may be denominated either rich or barren.

DIAMOND MINES.

The word _diamond_, is supposed to be a corruption of the word _adamant_, in allusion to the great hardness of this gem, which is the most valuable of all the precious stones. Diamonds were originally discovered in Bengal, and in the island of Borneo; and about the year 1720, were found in Brazil. They are found of all colors; and those which are colorless, or of some decided tint, are most esteemed, though the latter kind are very rare. Those which are slightly discolored are the least valuable.

The specific gravity of the diamond, is, to that of water, in the proportion of about three and a half to one. It is the hardest of all known substances, and can only be cut and polished by its own dust or powder. The art of splitting or cutting and polishing this gem, though probably of remote antiquity in Asia, was first introduced into Europe in 1486, by Louis Berghan, of Bruges, who accidentally discovered that by rubbing two diamonds together, their surfaces might be rendered smooth. And the fine powder which is rubbed off by such friction, serves to grind and polish them. The diamond is of the nature of _charcoal_, or pure carbon, and is combustible: under the blow-pipe it burns away in a blue, lambent flame.

The high value attached to diamonds does not depend so much on their beauty and hardness, as on their great scarcity, and the labor and expense necessary in procuring them. Hitherto they have been observed only in the torrid zone; and Brazil is the only part of America in which they have been found. The historical account of their discovery in that country is as follows. Near the capital of the territory of Serro do Frio flows the river Milho Verde, where it was the custom to dig for gold, or rather to extract it from the alluvial soil. The miners, during their search for gold, found several diamonds, which they were induced to lay aside in consequence of their particular shape and great beauty, although they were ignorant of their intrinsic value.

The diamond works on the river Jigitonhonha are described by Mr. Mawe as the most important in the Brazilian territory. The river, in depth from three to nine feet, is intersected by a canal, beneath the head of which it is stopped by an embankment of several thousand bags of sand, its deeper parts being laid dry by chain-pumps. The mud is now washed away, and the =cascalhao=, or earth which contains the diamonds, dug up, and removed to a convenient place for washing. The process, which is as follows, is seen in the cut on the next page. A shed, consisting of upright posts which support a thatched roof, is erected in the form of a parallelogram, in length about ninety feet, and in width forty-five. Down the middle of its area a current of water is conveyed through a canal covered with strong planks, on which the earth is laid to the thickness of two or three feet. On the other side of the area is a flooring of planks, from twelve to fifteen feet in length, imbedded in clay, extending the whole length of the shed, and having a gentle slope from the canal. This flooring is divided into about twenty compartments, or troughs, each about three feet wide, by means of planks placed on their edges; and the upper ends of these troughs communicate with the canal, being so formed that water is admitted into them between two planks about an inch separate from each other. Through this opening the current falls about six inches into the trough, and may be directed to any part of it, or stopped at pleasure, by means of a small quantity of clay. Along the lower ends of the troughs a small channel is dug, to carry off the water.

[Illustration: DIAMOND WASHING IN BRAZIL.]

On the heap of earth, at equal distances, three high chairs are placed for the overseers, who are no sooner seated than the negroes enter the troughs, each provided with a rake of a peculiar form, and having a short handle, with which he rakes into the trough from fifty to eighty pounds' weight of the earth. The water being then allowed to pass in by degrees, the earth is spread abroad, and continually raked up to the head of the trough, so as to be kept in constant motion. This operation is continued for a quarter of an hour, when the water begins to run clearer; and, the earthy particles having been washed away, the gravel-like matter is raked up to the end of the trough. At length the current flowing quite clear, the largest stones are thrown out, and afterward those of an inferior size; the whole is then examined with great care for diamonds. When a negro finds one, he instantly stands upright, and claps his hands; he then extends them, holding the gem between the fore-finger and the thumb. An overseer receives it from him, and deposits it in a bowl, suspended from the center of the structure, and half filled with water. In this vessel all the diamonds found in the course of the day are deposited, and at the close of the work are taken out and delivered to the principal overseer, who, after they have been weighed, registers the particulars in a book kept for that purpose.

When a negro is so fortunate as to find a diamond of the weight of seventeen carats and a half, the following ceremony takes place: he is crowned with a wreath of flowers, and carried in procession to the administrator, who gives him his freedom by paying his owner for it. He also receives a present of new clothes, and is permitted to work on his own account. For small stones proportionate premiums are given; while many precautions are taken to prevent the negroes from stealing the diamonds, with which view they are frequently changed by the overseers, lest these precious gems should be concealed in the corners of the troughs. When a negro is suspected of swallowing a diamond, he is confined in a solitary apartment, and means taken to bring the gem to light.

In the East Indies, the kingdom of Golconda, extending two hundred and sixty miles along the bay of Bengal, and having a breadth of two hundred miles from east to west, abounds in diamond mines. They are chiefly in the vicinity of the rocky hills and mountains which intersect the country, and in the whole of which diamonds are supposed to be contained. In several of the mines they are found scattered in the earth, within two or three fathoms of the surface, and in others are met with in a mineral substance in the body of the rocks, forty or fifty fathoms deep. The laborers having dug five or six feet into the rock, soften the stone by fire, and proceed till they find the vein, which often runs two or three furlongs under the rock. The earth being brought out and carefully searched, affords stones of various shapes, and of a good water. This earth is of a yellowish, and sometimes of a reddish color, frequently adhering to the diamond with so strong a crust that the separation becomes difficult.

To find the diamonds, the workmen form a cistern of a kind of clay, with a small vent on one side, a little above the bottom; in this vent they place a plug, and throwing into the cistern the earth they have dug, pour in water to dissolve it. They then break the clods, and stir the wet earth in the cistern, allowing the lighter part to be carried off in the form of mud, when the vent-hole is opened to let

out the water. They thus continue washing, until what remains in the cistern is pretty clean; and then, in the middle of the day, when the sun shines bright, carefully look over all the sand, at which practice they are so expert, that the smallest stone can not escape them. The brightness of the sun being reflected by the diamonds, aids them in their research, which would be foiled if a cloud were to intervene.

The largest known diamond was found in Brazil, and belongs to the king of Portugal. It weighs sixteen hundred and eighty carats; and, although uncut, it is valued at the enormous sum of two hundred and twenty-four millions sterling, which gives an estimate of nearly eighty pounds sterling for each carat, the multiplicand of the square of its whole weight being taken. The one next in magnitude and value, is probably that mentioned by Tavernier, in possession of the Great Mogul. It was found in Golconda in 1550; is of the size of half a hen's egg, and is said to weigh nine hundred carats. This diamond is the same as the famous "_Koh-i-noor_," or "Mountain of Light," now belonging to the queen of England, and which attracted so much attention in the great exhibition at London, in 1851. The one supposed to be next in value, is that belonging to the crown jewels of Russia, which weighs seven hundred and seventy-nine carats, and has been estimated at five millions sterling. But perhaps the most perfect and beautiful diamond hitherto found, is the one known as the Pitt diamond, which was brought from India by a gentleman of that name, who sold it to the Duke of Orleans for one hundred thousand pounds sterling. It was worn by Bonaparte in the hilt of his sword. It weighs about one hundred and thirty-six carats, or five hundred and forty-four grains. It ought, however, to be observed, that these estimates, founded on the magnitude and brilliancy of the gems, are very different from the prices which the most princely fortunes can afford to pay for them. The Russian diamond cost about one hundred and thirty five thousand pounds sterling; and the one called the Pitt or Regent, although it weighed one hundred and thirty-six carats only, was, on account of its greater brilliancy, purchased of a Greek merchant, for one hundred thousand pounds sterling. Several other large diamonds are preserved in the cabinets of the sovereigns and princes of Europe.

Why such immense value should be attached to diamonds, in all civilized countries, and by a kind of common consent, is one of those singular things that seem inexplicable. That a magnificent house, with a large estate, and the means of living not only in comfort but splendor, should be set in competition with, and even deemed inadequate to the purchase of, a transparent crystallized stone, not half the size of a hen's egg, seems almost a kind of insanity! If for the mere consciousness of possessing a diamond of less than the weight of an ounce, any private gentleman were to pay four hundred and fifty thousand dollars in ready money, and an annuity of twenty thousand dollars besides, he would probably be thought beside himself. And yet not only was the above sum given, but a patent of nobility into the bargain, by the empress Catharine, of Russia, for the famous diamond "Nadir Shah." In this case, however, though the seller acquired much, the purchaser did not suffer any personal privation; and in reality, notwithstanding the costliness and high estimation of diamonds, they are not put in competition with the substantial comforts and conveniences of life. Among ornaments and luxuries, however, they unquestionably occupy, and have ever occupied, the highest rank. Even Fashion, proverbially capricious as she is, has remained steady in this, one of her earliest attachments, during probably three or four thousand years. There must be, therefore, in the nature of things, some adequate reason for this universal consent; which becomes a curious object of inquiry.

The utility of the diamond, great as it is in some respects, enters for little or nothing into the calculation of its price; at least all that portion of its value which constitutes the difference between the cost of an entire diamond and an equal weight of diamond powder, must be attributed to other causes.

The beauty of this gem, depending on its unrivaled luster, is, no doubt, the circumstance which originally brought it into notice, and still continues to uphold it in the public estimation; and certainly, notwithstanding the smallness of its bulk, there is not any substance, natural or artificial, which can sustain any comparison with it in this respect. The vivid and various refractions of the opal, the refreshing tints of the emerald, the singular and beautiful light which streams from the six-rayed star of the girasol, the various colors, combined with high luster, which distinguish the ruby, the sapphire, and the topaz, beautiful as they are on a near inspection, are almost entirely lost to a distant beholder; whereas the diamond, without any essential color of its own, imbibes the pure solar ray, and then reflects it, either with undiminished intensity, too white and too vivid to be sustained for more than an instant by the most insensible eye, or decomposed by refraction into those prismatic colors, which paint the rainbow, and the morning and evening clouds, combined with a brilliancy which hardly yields to that of the meridian sun. Other gems, inserted into rings and bracelets, are best seen by the wearer; and if they attract the notice of the bystanders, divide their attention, and withdraw those regards which ought to be concentered on the person, to the merely accessory ornaments. The diamond, on the contrary, whether blazing on the crown of state, or diffusing its starry radiance from the breast of titled merit, or "in courts of feasts and high solemnities," wreathing itself with the hair, illustrating the shape and color of the neck, and entering ambitiously into contest with the

lively luster of those eyes that “rain influence” on all beholders, blends harmoniously with the general effect, and proclaims to the most distant ring of the surrounding crowd, the person of the monarch, of the knight, or of the beauty.

Another circumstance tending to enhance the value of the diamond is, that although small stones are sufficiently abundant to be within the reach of moderate expenditure, and therefore afford, to all those who are in easy circumstances an opportunity to acquire a taste for diamonds, yet those of a larger size are, and ever have been, rather rare; and of those which are celebrated for their size and beauty, the whole number, at least in Europe, scarcely amounts to half a dozen, all of them being in possession of sovereign princes. Hence, the acquisition even of a moderately large diamond, is what mere money can not always command; and many are the favors, both political and of other kinds, for which a diamond of a large size, or of uncommon beauty, may be offered as a compensation, where its commercial price, in money, neither can be tendered, nor would be received. In many circumstances also, it is a matter of no small importance for a person to have a considerable part of his property in the most portable form possible; and in this respect what is there that can be compared to diamonds, which possess the portability, without the risk of bills of exchange? It may further be remarked, in favor of this species of property, that it is but little liable to fluctuation, and has gone on pretty regularly increasing in value, insomuch that the price of stones of good quality is considerably higher than it was some years ago.

The art of cutting and polishing diamonds, has a twofold object; first, to divide the natural surface of the stone in a symmetrical manner by means of highly polished polygonal planes, and thus to bring out, to the best advantage, the wonderful refulgence of this beautiful gem; and, secondly, by cutting out such flaws as may happen to be near the surface, to remove those blemishes which materially detract from its beauty, and consequently from its value. The removal of such flaws is a matter of great importance; for, owing to the form in which the diamond is cut, and its high degree of refrangibility, the smallest fault is magnified, and becomes obtrusively visible to all. For this reason, also, it is by no means an easy matter, at all times, to ascertain whether a flaw is or is not superficial; and a person with a correct and well-practiced eye, may often purchase to great advantage, stones which appear to be flawed quite through, but which are in fact only superficially blemished.

Before leaving the subject of diamonds, it may be well to notice some other valuable stones that are much sought and prized for ornament. One of these is the _oriental ruby_. This, in its most esteemed color, is pure carmine, or a blood-red of considerable intensity, forming, when well polished, a blaze of the most exquisite and unrivaled tint. It is, however, more or less pale, and mixed with blue in various proportions; and hence it occurs rose-red, and reddish-white, crimson, peach-blossom red, and lilac-blue, the latter variety being named the _oriental amethyst_. It is a native of Pegu, and is said to be found in the sand of certain streams near the capital of the country; and it also occurs, with the sapphire, in the sands of the rivers of Ceylon. A ruby which is perfect both in color and transparency, is much less common than a good diamond; and when of the weight of three or four carats, is even more valuable than a diamond of the same size. The king of Pegu, and the monarchs of Asia and Siam, monopolize the finest rubies, in the same way as the sovereigns of India make a monopoly of diamonds. The finest ruby in the world is in possession of the first of these kings. Its purity has passed into a proverb, and its worth, when compared with gold, is inestimable. The dubah of Deccan, also, possesses a remarkably fine one, which is a full inch in diameter. The princes of Europe can not boast of any rubies of first-rate magnitude.

The _oriental sapphire_ ranks next in value to the ruby. When it is perfect, its color is a clear and bright Prussian blue, united to a high degree of transparency. The _astoria_ or _star-stone_, is a remarkable variety of this beautiful gem: it is semi-transparent, with a reddish purple tinge. And beside these, there are the _red_ sapphire, often called the oriental ruby, and the _yellow_ sapphire, which is called the oriental topaz. And in addition to these precious stones, or gems, there are also the _emerald_, of a beautiful green color; the _topaz_, which is of a yellow or light wine-color, and which by being heated, sometimes becomes rose-red, so as to be passed off as a ruby; the _jasper_ and _chalcedony_, which are of various colors; the _onyx_, which is a regularly banded agate, much prized for cameos, especially where the colors are very distinct and different; the _cornelian_, which is properly a red or flesh-colored chalcedony, much valued for seal-stones, &c.; and the _blood-stone_, or _heliotrope_, which is deep green, and somewhat translucent, and variegated by blood-red spots: all of which are much used in the various departments of jewelry.

We have reserved for this place, a notice of the hot-well at Clifton, England, which would have been mentioned in connection with the Geysers and other hot springs, but from its connection with the beautiful crystals known as _Bristol stones_ or _diamonds_, some of which are so hard as to cut glass, and are exceedingly clear, colorless and brilliant. When set in rings, in their natural state, these stones often appear of as high a polish and luster, as if they had been wrought by the most skillful lapidary.

The warm spring, or fountain, in the vicinity of which they are found, is called the _hot-well_. It is in the parish of Clifton, and is so copious as to discharge sixty gallons of water in a minute. It rises forcibly from an opening in the solid rock, at about twenty-six feet

below high-water mark. On its immediate influx from the rock, the water is much warmer than when it is pumped up for drinking, for it is raised by pumps some thirty feet. Its qualities in a medicinal point of view are supposed to be valuable; but it is not on this point that we propose to dwell, and therefore we pass on to the rocks in the neighborhood, near which the _Bristol stones_ are found. Just below the hot-well, there rises a noble range of hills, which are not more remarkable for their hight, than for their being equally so on both sides the river, the strata in some places answering on each side for about a mile and a half in a serpentine course. These constitute one of the greatest natural curiosities in England. The rock beyond the hot-well, and on the same side, is named St. Vincent's, a chapel dedicated to that saint having been formerly built on its summit. It is in hight three hundred feet, and has a majestic appearance. It supplies the naturalist with many curious fossils, the botanist with a variety of scarce plants, the antiquary with the remains of a Roman camp, and the less curious inquirer with a view of a most dreadful and surprising precipice.

The rocks in general, when broken up, are of a dusky red, brown or chocolate colored marble, very hard and close-grained, and which, on being struck with a hammer, emit a strong sulphureous smell. It will bear a polish equal to any foreign marble; and, when sawed into slabs and polished, appears beautifully variegated with veins of white, bluish-gray, or yellow. It is often employed for chimney-pieces; but it is principally used for making lime, for which purpose there is no stone in England so well calculated, nor is there any lime so strong, fine, and white, which excellent qualities occasion great demand for foreign consumption.

Here, and in the vicinity, laborers are daily employed in blowing up the rocks with gunpowder, by which process vast fragments are frequently thrown down, and repeatedly strike the precipice with a dreadful crash, which, combined with the loud report of the explosion, reëchoed from side to side by the lofty cliffs, makes a noise resembling thunder, for which it is frequently mistaken by strangers. It is the opinion of the greater part of those who have viewed these rocks, that they were once united, and were separated by some terrible convulsion of nature. A bridge of one arch, from rock to rock, over the Avon, has long been in contemplation; but if the blowing up of these rocks should still be persisted in, the design will be rendered impracticable. This is the more to be regretted, because stone of the same quality is to be procured lower down the river.

Now it is in the fissures and cavities of these rocks, that the beautiful crystals called _Bristol stones_, or _diamonds_, already mentioned, are found. They are clear and brilliant, and being without color, so richly and brilliantly reflect the light, as to be almost next to the diamond in appearance, and are often palmed off on the unpracticed for the latter gem. They are extensively used in many of the plainer kinds of jewelry, and when set over gold-leaf, or thin paper of delicate tinges, are often made closely to resemble some of the richest gems known.

GOLD AND SILVER MINES.[4]

The mines of La Plata, so denominated on account of the abundance of silver they contain, are chiefly situated in the provinces which were formerly attached to the Spanish viceroyalty of Rio de la Plata; but which, since the South American states revolted from the mother country, have been included in the republic of Bolivia, or Upper Peru as it is sometimes called. With the exception of Mexico, Bolivia is the richest country in silver which has yet been discovered, and contains innumerable mines both of that metal and of gold. All its northern provinces teem with mineral opulence; and those of Laricaja and Carabaya, have been distinguished by the production of the latter, and still nobler metal, in its virgin state. In consequence, however, of the recent political convulsions, mining, once the richest source of revenue, is in a depressed state; many of the mines being filled with water and totally neglected.

Footnote 4:

The account of the mines of South America and Mexico is mostly from Humboldt, and as will be obvious to the reader, has reference in many things to their past history and progress, rather than to their present condition.

The mountain of Potosi formerly produced weekly about five thousand marks of silver, that is, from thirty to forty thousand dollars; a surprising produce, when it is considered that it has been wrought since 1545, at which time it was accidentally discovered by an Indian, or native, as represented in the cut. In hunting some goats, he slipped from a slight elevation, and to save himself caught hold of a shrub, which coming away from the ground, laid bare the silver at its root. At the commencement it was still more abundant, and the metal was dug up in a purer state.

[Illustration: DISCOVERY OF SILVER IN PERU.]

The silver was often found in shoots like roots, imbedded in the earth. Six thousand Indians were sent every eighteen months, from the provinces of the viceroyalty, to work this mine. The expedition was called _mita_; and these Indians, having been enrolled and formed into parties, were distributed by the governor of Potosi, and received a small daily stipend, (equal to about thirty-four cents

of our currency,) until the period of their labor was completed. They were thus doomed to a forced service, nothing less than slavery, so long as it lasted, which the Spaniards have endeavored to justify by the plea that laborers could not otherwise be procured.

Lumps of pure gold and silver, called =papas=, from their resemblance to the potato, were often found in the sands. The poor likewise occupied themselves in =lavaderos=, or in washing the sands of the rivers and rivulets, in order to find particles of the precious metals.

To compensate for the mines rendered useless by the irruption of water, or other accidents, rich and new ones were daily discovered. They were all found in the chains of mountains, commonly in dry and barren spots, and sometimes in the sides of the =quebredas=, or astonishing precipitous breaks in the ridges. However certain this rule might be in the region of Bolivia, it was contradicted in that of Peru, where, at three leagues' distance from the Pacific ocean, not far from Tagna, in the province of Arica, there was discovered the famous mine of Huantajaya, in a sandy plain at a distance from the mountains, of such exuberant wealth that the pure metal was cut out with a chisel. From this mine a large specimen of virgin silver is preserved in the royal cabinet of natural history at Madrid. It attracted a considerable population, although neither water nor the common conveniences for labor could be found there, neither any pasturage for the cattle.

In the mint of Potosi, about six millions of dollars were annually coined; and the mines of the old viceroyalty of La Plata, taken collectively, are reckoned to have yielded about sixteen millions.

The mines of Mexico, or what was formerly called New Spain, have been more celebrated for their riches than those of La Plata, notwithstanding which they are remarkable for the poverty of the mineral they contain. A quintal, or sixteen hundred ounces of silver ore, affords, at a medium, not more than three or four ounces of pure silver, about one-third of what is yielded by the same quantity of mineral in Saxony. It is not, therefore, on account of the richness of the ore, but from its abundance and the facility of working it, that these mines have been so much superior to those of Europe.

The fact of the small number of persons employed in working them, is not less contrary to the commonly received opinion on this subject. The mines of Guanaxuato, infinitely richer than those of Potosi ever were, afforded from 1706 to 1803, nearly forty millions of dollars in gold and silver, or very nearly five millions of dollars annually, being somewhat less than one-fourth of the whole quantity of gold and silver from New Spain; notwithstanding which, these mines, productive as they were, did not employ more than five thousand workmen of every description. In Mexico, the labor of the mines was perfectly free, and better paid than any other kind of industry, a miner earning from five to five dollars and a half weekly, while the wages of the common laborer did not exceed a dollar and a half. The =tenateros=, or persons who carried the ore on their backs, from the spot where it was dug out of the mine, to that where it was collected in heaps, had a sum equal to a dollar and ten cents for a day's work of six hours. Neither slaves, criminals, nor forced laborers, were employed in the Mexican mines.

In consequence of the clumsy, imperfect and expensive mode of clearing them from water, several of the richest of these mines have been overflowed and abandoned; while the lack of method in the arrangement of the galleries, and the absence of lateral communications, have added to the risk, and greatly increased the expense of working them. Labor has not been, as in the working of the European mines, abridged, nor the transportation of materials facilitated. When new works were undertaken, a due consideration was not bestowed on the preliminary arrangements; and they were always conducted on too large and expensive a scale.

More than three-fourths of the silver obtained from America is extricated from the ore by means of quicksilver, the loss of which, in the process of amalgamation, is immense. The quantity that used to be consumed annually in Mexico alone, was about sixteen thousand quintals; and in the whole of South America, about twenty-five thousand quintals were yearly expended, the cost of which there, has been estimated at more than a million dollars. The greater part of this quicksilver, in later years, was furnished by the mine of Almaden in Spain, and that of Istria in Carniola, the celebrated quicksilver mine of Huancavelica in Peru, having greatly fallen off in its produce since the sixteenth century, when it was highly flourishing. The prosperity of the silver mines, both in Mexico and Peru, therefore depended very much on the supplies of quicksilver from Spain, Germany and Italy; for such was the abundance of the ore in those provinces, that apparently the only limit to the amount of silver obtained there, was the want of mercury for amalgamation.

In taking a general view of the riches of the other portions of America, Humboldt, who has supplied these details, remarks that, in Peru, silver ore exists in as great abundance as in Mexico, the mines of Lauricocha being capable of yielding as great a produce as

those of Guanaxuato; but that the art of mining, and the methods of separating the silver from its ore, are still more defective than in Mexico. Notwithstanding this imperfect system, the total amount of the precious metals annually furnished by America, was at one time estimated at upward of forty-two million dollars; the gold being in proportion to the silver as one to forty-six. From 1492 to 1803, the quantity of gold and silver extracted from the American mines, was equal in value to five billion, seven hundred and six million, seven hundred thousand dollars; of which immense sum, the portion carried to Europe, including the booty gathered by the conquerors of America, is estimated at five billion, four hundred and forty-five million dollars, averaging seventeen million and a half of dollars yearly. The annual importation up to 1803, being divided into six periods, appears to have constantly augmented, and in the following progressive ratio. From 1492 to 1500, it did not exceed two hundred and fifty thousand dollars. From 1500 to 1545, it amounted to three millions of dollars. From 1545 to 1600, to eleven millions. From 1600 to 1700, to sixteen millions. From 1700 to 1750, to twenty-two millions and a half. And, lastly, from 1750 to 1803, to the prodigious sum of thirty-five million, three hundred thousand dollars.

The first period was that of exchange with the natives, or of mere rapine. The second was distinguished by the conquest and plunder of Mexico, Peru and New Granada, and by the opening of the first mines. The third began with the discovery of the rich mines of Potosi; and in the course of it the conquest of Chili was completed, and various mines opened in Mexico. At the commencement of the fourth period, the mines of Potosi began to be exhausted; but those of Lauricocha were discovered, and the produce of Mexico rose from two millions to five millions of dollars annually. The fifth period began with the discovery of gold in Brazil; and the sixth was distinguished by the prodigious increase of the mines of Mexico, while those of every other part of America, with the exception of Brazil, were then constantly improving.

The gold mines of Brazil have been very productive. Those called general, were about seventy-five leagues from Rio Janeiro, the staple and principal outlet of the riches of the Brazilian territory. They formerly yielded to the king, annually, for his right of fifths, at least one hundred and twelve arobas (weighing twenty-five pounds each) of gold; so that their yearly produce might then have been estimated at upward of three and a half millions of dollars, and that of the more distant mines at about one-third the sum.

The gold drawn from them could not be carried to Rio Janeiro, without being first brought to the smelting-houses established in each district, where the right of the crown was received. What belonged to private persons was remitted in bars, with their weight, number, and an impression of the royal arms. The gold was then assayed, and its standard imprinted on each bar. When these bars were carried to the mint, their value was paid to the possessor in coin, commonly in half-doubloons, each worth eight Spanish dollars. Upon each of these half-doubloons the king gained a dollar, by the alloy and right of coinage. The mint of Rio Janeiro was one of the most beautiful in existence, and furnished with every convenience for working with the greatest celerity. As the gold came from the mines at the same time that the fleets came from Portugal, the operations of the mint and the coinage proceeded with surprising quickness.

In Africa, the kingdom of Mozambique abounds in gold, which is washed down by the rivers, and forms a chief part of the commerce of the country. The kingdoms of Monomotara and Sofala likewise furnish considerable quantities of gold; and the Portuguese residing in the latter territory, half a century ago, reported that it yielded annually two millions of =metigals=, equal to somewhat more than a million sterling. The merchants exported from Mecca, and other parts, about the same quantity of gold. The soldiers were paid in gold dust, in the state in which it was collected; and this was so pure, and of so fine a yellow, as not to be exceeded, when wrought, by any other gold beside that of Japan. Gold is likewise found on the island of Madagascar. The Gold Coast is so denominated from the abundance of gold found among the sands: it is not, however, so productive as has been generally supposed, owing to the intense heats, which, in a great measure, prevent the natives from prosecuting their researches.

In Asia, the island of Japan is most productive of gold, which is found in several of its provinces, and is, in by far the greater proportion, melted from its ore. It is also procured by washing the sands, and a small quantity is likewise found in the ore of copper. The emperor claims a supreme jurisdiction, not only over the gold mines, but over all the mines of the empire, which are not allowed to be worked without a license from him. Two-thirds of their produce belong to him, and the other third is left to the governor of the province in which the mines are situated. But the richest gold ore, and that which yields the finest gold, is dug in one of the northern provinces of the island of Niphon, a dependency of Japan, where the gold mines have, in past times, been highly productive, though now they have much fallen off. In the Japanese province of Tsckungo, a rich gold mine, having been filled with water, was no longer worked: as it was, however, so situated, that by cutting the rock and making an opening beneath the mine, the water could be easily drawn off, this was attempted. At the moment of beginning the operation, so violent a storm of thunder and lightning arose, that the workmen were obliged to seek shelter elsewhere; and these superstitious people imagining that the tutelar god and protector of the spot, unwilling to have the bowels of the earth thus rifled, had raised the storm to make them sensible of

his great displeasure at such an undertaking, desisted from all further attempts, through the fear of incurring his displeasure, and could not be induced to go on with it.

Thibet, a mountainous country of India, contains a great abundance of gold, which is traced in the rivers flowing from that territory into the Ganges. In Hindoostan there are not any mines of gold; but in the Irnada district gold is collected in the river which passes Nelambur in the Mangery Talui, a nair having the exclusive privilege of this collection, for which he pays a small annual tribute. Silver is in general rare throughout the oriental regions, and there is not any indication of this metal in India; but in Japan there are several silver mines, more particularly in the northern provinces, and the metal extracted from them is very pure and fine.

Turning to Europe, Dalmatia is said in ancient times to have produced an abundance of gold. Pliny reports that in the reign of the emperor Nero, fifty pounds of this precious metal were daily taken from the mines of that province; and that it was found on the surface of the ground. It is added, that Vibius, who was sent by Augustus to subdue the Dalmatians, obliged that hardy and warlike people to work in the mines, and to separate the gold from the ore.

Bossina, in Sclavonia, contains many mineral mountains, and has rich mines of gold and silver. The district in which the latter are found, is named the =Srebrarniza=, being derived from the word =srebr=, which signifies silver in all the Sclavonian dialects. Their produce resembles the native silver of Potosi, and is found, combined with pure quartz, in small, thin leaves, resembling moss.

The kingdom of Norway formerly produced gold; but the expense of working the mines, and procuring the pure ore, being greater than the profit, these have been neglected. There are, however, silver mines, which are extremely valuable, and give employment to several thousands of persons. The principal of these is at Königsberg, and was discovered in 1623, when the town was immediately built, and peopled with German miners. In 1751, forty-one shafts and twelve veins, were wrought in this mine, and gave employment to thirty-five hundred officers, artificers and laborers. A view of one part of this mine is given in the cut on the next page.

The silver ore is not, as was at first imagined, confined to the mountain between Königsberg and the river Jordal, but extends its veins for several miles throughout the adjacent districts, in consequence of which new mines have been undertaken in several places, and prosperously carried on. One of the richest and most ancient of the mines, named “Old God’s blessing,” has sometimes, in the space of a week, yielded several hundred pounds’ weight of rich ore. The astonishing depth of this mine, which is not less than a hundred and eighty fathoms, perpendicularly, fills the mind of the beholder with amazement; and the circumference at the bottom forms a clear space of several hundreds of fathoms. Here the sight of thirty or forty fires, burning on all sides in this gloomy cavern, and continually fed to soften the stone in the prosecution of the labors, seems, according to the notions commonly entertained, an apt image of hell; and the swarms of miners, covered with soot, and bustling about in habits according to their several employments, may well remind one of so many evil spirits; more especially when, at a given signal that the mine is to be sprung in this or that direction, they exclaim aloud: “=Berg-livet, berg-livet=!” “Take care of your lives.”

[Illustration: SILVER MINE AT KÖNIGSBERG.]

The gold mines of Cremnitz, in Hungary, lie forty miles south of the Carpathian hills; and twenty miles further to the south are the silver mines of Shemnitz. These are called mining towns; and the former is the principal, its rich ores being found in what is styled metallic rock. Its mines also produce a certain proportion of silver. Hungary is beside enriched by a mineral peculiar to itself, or one, at least, which has not hitherto been discovered elsewhere, namely, the _opal_, a gem preferred to all others by the oriental nations. The opal mines are situated at Ozerwiniza, where they are found in a hill consisting of decomposed porphyry, a few fathoms beneath the surface. Their produce is of various qualities, from the opaque-white, or semi-opal, to the utmost refulgence of the lively colors by which this noble gem is distinguished.

Transylvania and the Bannet, contain numerous and valuable mines, consisting chiefly of gray gold ore, and white gold ore. The finest gold is found at Olapian, not far from Zalathna, intermixed with gravel and sand. The sands of the Rhine, also, in various places contain traces of gold.

The mountains of Spain were, according to ancient writers, very rich in gold and silver; and accordingly Gibbon calls that kingdom, “the Peru and Mexico of the old world.” He adds, that “the discovery of the rich western continent of the Phenicians, and the oppression of the simple natives, who were compelled to labor in their own mines for the benefit of strangers, form an exact type of the more recent history of Spanish America.” The Phenicians were acquainted only with the sea-coasts of Spain; but avarice, as well as ambition, carried the arms of Rome and Carthage into the heart of the country, and almost every part of the soil was found

pregnant with gold, silver and copper. A mine near Carthagena, is said to have yielded daily twenty-five thousand drams of silver, or over thirteen hundred thousand dollars a year. The provinces of Asturia, Gallicia and Lusitania, yielded twenty thousand pounds' weight of gold annually: but rich as these mines are, the modern Spaniards have chosen rather to import the precious metals from America, than to seek them at home.

Portugal is in many parts mountainous; and these mountains contain, beside others, rich ores of silver. But the Portuguese, like the Spaniards, having been supplied with metals from South America, and particularly with an abundance of gold and silver from Brazil, have not worked the mines in their own country. Gems of all kinds, as turkoises and hyacinths, are also found in these mountains, together with beautifully variegated marbles, and many curious fossils.

But the richest and most productive gold mines of Europe, at the present time, are probably those of Russia. It had long been known that gold was to be found in the Russian dominions; but in 1829, Baron Humboldt, with two scientific associates, at the request of the emperor of Russia, made a mineralogical tour to the Ural and Altai mountains. In this journey, they not only discovered new localities of gold and silver, but from the geological features of the country suggested that, at certain localities, diamonds would also probably be found, which accordingly happened. And as the result of the report they made to the Russian government, mining operations were commenced on a large scale in these mountains, which have now become one of the most prolific gold regions in the world. The increase of these sources of gold, in extent and amount, has been such, that from the value of about ten thousand dollars in 1836, the amount received in 1843, was some eighteen millions of dollars; and the supply has since increased annually, until at present, 1855, it amounts to about twenty million dollars a year. Most of this large amount of gold is gathered from washing the sand and loose earth, and not from deep mines; and as it is every year becoming greater and greater, it must add immensely to the wealth and resources of the Russian empire.

But by far the greatest gold-field in the world, has been opened by the discoveries of the last few years in California. At the close of the late war with Mexico, the United States acquired, by conquest and purchase, a tract of country of some five hundred thousand square miles in extent, known as the Mexican territory of upper California. And from the western portion of this region, Congress, in 1850, created and admitted into the American confederacy, the thirty-first state, under the name of California. It is almost superfluous to say, that California is one of the most important mineral regions in the world, particularly in its deposits of gold. Vague notions of the existence of this gold, had from time to time been spread abroad; but it was not till 1848, that an accident discovered the marvelous fact of its abundance. In that year, a Mr. Sutter, a native of Switzerland, was settled near the mouth of the American fork of the Sacramento river, at the head of navigation, one hundred and fifty miles from its mouth. Here he had founded New Helvetia, and obtained a grant of thirty miles round. He had sent some men to the upper part of the American fork, to clear out a mill-race. The soil was washed down in the process, and some shining scales laid bare. These proved to be gold, and on investigation, not only the valley of this stream, but the beds of all the other streams running into the Sacramento, were found to have a soil full of gold, in minute scales and in bits, from a grain to many ounces in weight. New "placers," as the "washings," or "dry diggings" are called, have constantly been discovered, and people have rushed to these hills from all quarters, with pans, tubs, pickaxes, shovels, hoes, filtering-machines, and energetic sinews, till they have extracted, by digging, washing, &c., millions on millions of dollars' worth of the yellow treasure. Gold is now found over an extent of many hundred miles, and also on the Gila, and throughout the great central plateau, north and north-east of it.

In a favorable locality, the lucky finder of a placer will sift out hundreds of dollars' worth in a day. Persons with not a shirt to their backs, and scarcely a whole garment upon them, are seen with bags of gold in their hands. Prices of everything went up at once to an enormous rate: laborer's wages became eight or ten dollars a day; cooks at the diggings, ten dollars a day; clerks, fifteen hundred dollars to six thousand dollars =per annum=, &c., &c. As all the productive industry of the country is now turned to gold-digging, and as such vast numbers of consumers are flocking in from all parts, prices continue to range high for every article of necessity, although such large quantities of goods have been sent.

[Illustration: GOLD WASHING IN CALIFORNIA.]

The gold first discovered was evidently not in its original place, but had been washed down from higher regions; and when all that is thus spread through the sands of California shall have been exhausted, if it ever shall be, there are large bodies of auriferous quartz, which (with greater labor and expense) will doubtless afford large supplies of gold for generations to come. The amount of capital invested in quartz-mining, according to the state census of 1852, was about six millions, and in placer and other mining operations, about four millions of dollars; and the sum total of these amounts has been greatly increased since that date. Up to the close of 1851, there had been deposited in the United States mint, $98,407,990 of California gold; and the deposits of 1852

amounted to $46,528,076, making a total of $145,000,000. But all this falls far short of the real amount produced; as probably quite as much more has been sent to Europe in the shape of dust or bullion, not to mention the unreported sums which have been privately taken out of the state. An official estimate states the production of American gold in 1853, at $109,156,748; and of this sum nearly the whole is from the mines of California. And this vast amount is steadily on the increase, in about the proportion of the increase of the mining population, so that California not only is, but is likely to continue to be _the great gold-field_ of the world.

Before leaving California, it may not be amiss to add, that the country abounds in mines of almost every kind, as well as gold. Quicksilver, plaster, lead, iron, silver, copper, asphaltum and marble, are found in Butte, and also in Marion county; rich silver mines and coal, in San Louis Obispo; copious salt springs, in Shasta; bituminous springs, in many places along the coast; hot sulphur springs, in Santa Barbara; warm soda springs, near Benicia; and platina is said to be widely distributed in almost every section where gold has been found. Silver has been discovered in several mines in the southern district; copper is widely distributed in other sections beside those above-mentioned; chromium occurs in large quantities in the serpentine rocks; and diamonds are reported to have been recently found in several localities.

[Illustration: PLACE WHERE GOLD WAS FIRST DISCOVERED IN AUSTRALIA.]

At a date still later than the discovery of gold in California, the same precious metal was discovered in Australia. The cut on the following page gives a view of the place where it was first found, in the county of Bathurst, not far from Sydney in New South Wales. It is worthy of note that we owe the discovery of gold in Australia to the high state of geological science. Sir R. Murchison, in his address to the London Geographical Society in 1844, alluded to the possibly auriferous character of the great eastern chain of Australia, being led thereto by his knowledge of the auriferous chain of the Ural, and by his examination of Count Strzelecki's specimens, maps and sections. Some of Sir R. Murchison's observations having found their way to the Australian papers, a Mr. Smith, at that time engaged in some iron works at Berrima, was induced by them in the year 1849 to search for gold, and he found it. He sent the gold to the colonial government, and offered to disclose its locality on payment of five hundred pounds sterling. The government, however, not putting full faith in the statement, and being, moreover, unwilling to encourage a gold fever without sufficient reason, declined to grant the sum, but offered, if Mr. Smith would mention the locality, and the discovery was found to be valuable, to reward him accordingly. Very unwisely, as it turned out, Mr. Smith did not accept this offer; and it remained for Mr. Hargraves, who came with the prestige of his California experience, to make the discovery anew, and get the reward from the English government on their own conditions. The first discovery was made in the banks of the Summer Hill creek and the Lewis Ponds river, small streams which run from the northern flank of the Conobalas down to the Macquarrie. The gold was found in the sand and gravel accumulated, especially on the inside of the bends of the brook, and at the junction of the two water-courses, where the stream of each would be often checked by the other. It was coarse gold, showing its parent site to be at no great distance, and probably in the quartz veins traversing the metamorphic rocks of the Conobalas. Mr. Stutchbury, the government geologist, reported on the truth of the discovery, and shortly afterward found gold in several other localities, especially on the banks of the Turon, some distance north-east of the Conobalas. This was a much wider and more open valley than the Summer Hill creek, and the gold accordingly was much finer, occurring in small scales and flakes. It was, however, more regularly and equably distributed through the soil, so that a man might reckon with the greatest certainty on the quantity his daily labor would return him. At the head of the Turon river, among the dark glens and gullies in which it collects its head-waters, in the flanks of the Blue mountains, the gold got "coarser," occurred in large lumps or nuggets, but these were more sparingly scattered.

As already said, the discovery was made by Mr. Hargraves, in May, 1850; and before the end of June, there were more than twenty thousand persons at the mines. When it was known in the town of Bathurst, that the discovery had been made, and that the country, from the mountain ranges, back to an indefinite extent in the interior, was probably one immense goldfield, the excitement was intense and universal. A complete phrensy seemed to seize on the entire population; the business of the town was paralyzed; and there was a universal rush to the diggings. People of all trades, callings and pursuits were quickly transformed into miners; and many a hand which had been trained to kid gloves, or accustomed only to the quill, became nervous to clutch the pick or crowbar, or to "rock the cradle" at the newly discovered mines. The roads were literally alive with the crowds pressing on from every quarter, some armed with pickaxes, others shouldering crowbars and shovels, and not a few strung round with hand-basins, tin-pots and cullenders. Scores rushed from their homes, with only a blanket, and a pick or grubbing-hoe, full of hope that a few days would give them heaps of the precious metal. Everything at once rose in price, and the whole face of society was speedily changed in almost every aspect.

The first pieces found were in grains. Soon a piece was picked up weighing some eleven ounces; and soon after, several lumps weighing together about three pounds. Gold was speedily discovered in almost every place where it was looked for; in the beds of

the streams, and in veins of quartz, in grains, in scales, and in lumps of various weights. Some, as might be expected, were successful, and some comparatively unsuccessful in seeking it; the great mass of the miners averaging not more than four or five dollars a day, while in some rare cases a single individual gathered to the value of a thousand dollars in the same time. Gold was soon discovered in the Wellington district, and in various other places. One piece was picked up weighing almost five pounds; and from a single cleft in a rock, a miner took out eleven pounds' weight of gold, in separate pieces of various sizes. A Scotchman gathered fourteen hundred dollars' worth in four days, and eight of his associates averaged from thirty to forty dollars' worth a day. Apparently there is no end to the supply, at least for years to come; and all this within forty miles of a town where every comfort, not to say luxury, can be obtained, with a good post-road all the way to Sydney, and in the midst of tracts of the most fertile land, partly occupied, and where food may be supplied for millions of inhabitants, if needed. An official statement estimates the supply of Australian gold at sixty million dollars a year; and in addition to the gold, diamonds and platinum have also been found. Australia and California are likely to be the great sources of the supply of gold, compared with which all others will be relatively unimportant.

Before leaving the subject of gold, it may be interesting to the reader to trace the process of its coinage, which may thus be briefly stated. The metal, after being received in the deposit-room, is carefully weighed, and a receipt given. Each deposit is then melted separately in the melting-room, and molded into bars. These bars next pass through the hands of the assayer, who with a chisel chips a small fragment from each one. Each chip is then rolled into a thin ribbon, and filed down until it weighs exactly ten grains. It is then melted into a little cup made of calcined bone ashes, and all the base metals, copper, tin, &c., are absorbed by the porous material of the cup or carried off by oxydation. The gold is then boiled in nitric acid, which dissolves the silver which it contains, and leaves the gold pure. It is then weighed, and the amount which it has lost gives the exact proportion of impurity in the original bar, and a certificate of the amount of coin due the depositor is made out accordingly. After being assayed, the bars are melted with a certain proportion of silver, and being poured into a dilution of nitric acid and water, assume a granulated form. In this state the gold is thoroughly boiled in nitric acid, and rendered perfectly free from silver or any other baser metals which may happen to cling to it. It is next melted with one-ninth its weight of copper, and, thus alloyed, is run into bars, and delivered to the coiner for coinage. The bars are rolled out in a rolling-mill until nearly as thin as the coin which is to be made from them. By a process of annealing they are rendered sufficiently ductile to be drawn through a longitudinal orifice in a piece of steel, thus reducing the whole to a regular width and thickness. A cutting-machine next punches small round pieces from the bar, about the size of the coin. These pieces are weighed separately by the "adjusters," and if too heavy are filed down; if too light they are melted again. The pieces which have been adjusted are run through a milling-machine, which compresses them to the right diameter and raises the edge. Two hundred and fifty are milled in a minute by the machine. They are then again softened by the process of annealing, and after a thorough cleaning are placed in a tube connecting with the stamping instrument, and are taken thence one at a time by the machinery, and stamped between the dies. They are now finished, and, being thrown into a box, are delivered to the treasurer for circulation. The machinery, of course, for all those processes, must be of the nicest kind. When in full operation, a mint like that of England, or that of the United States at Philadelphia, can coin millions on millions in a year.

QUICKSILVER MINES.

Quicksilver, or mercury, is the only metal which remains liquid at ordinary temperatures. It is white and very brilliant, as may be seen in common thermometers. It boils at six hundred and sixty degrees of heat; and freezes, and assumes a crystalline texture, at forty degrees below zero. It is extensively used in its various forms in the arts, and also for medicinal purposes. The thermometer and barometer illustrate some of its uses in its pure state; the backs of our common mirrors are covered with it, which gives them their reflecting power; it is used extensively in separating some of the purer metals from the mixtures with which they are found; and in some of its forms or combinations, it is the basis of calomel, corrosive sublimate, vermilion, &c.

Mercury is found in various parts of the world. Among its principal mines are those of Almaden, near Cordova, in Spain, and of Idria, near Carniola, in Austria; though it is also found in Peru, California, Italy and China. Formerly most of the quicksilver came from Germany; but more recently the largest production is probably in Spain. So extensively is it used, that in 1831, over three hundred thousand pounds were brought from the continent into England; and for the fourteen years ending in 1828, the imports of it into Canton, by the English and Americans, averaged nearly six hundred and fifty thousand pounds a year, worth some three hundred and fifty thousand dollars.

Of all the quicksilver mines, those of Idria, mentioned above, are some of the most interesting, and demand a particular description, as they have been celebrated in natural history, poetry and romance. The ban of Idria, is a district of Austria, lying west of Carniola. The town, which is small, is seated in a deep valley, amid high mountains, on the river of the same name, and at the bottom of so

steep a descent, that its approach is a task of great difficulty, and sometimes of danger.

The mines were discovered in 1497, before which time that part of the country was inhabited by a few coopers only, and other artificers in wood, with which the territory abounds. One evening, a cooper having placed a new tub under a dropping spring, to try if it would hold water, on returning the next morning, found it so heavy that he could scarcely move it. He at first was led by his superstition to suspect that the tub was bewitched; but spying, at length, a shining fluid at the bottom, with the nature of which he was unacquainted, he collected it, and proceeded to an apothecary at Laubach, who, being an artful man, dismissed him with a small recompense, requesting that he would not fail to bring him further supplies. From this small beginning, the product of these mines has steadily increased; and now might easily be made six hundred tuns per year, though to uphold the price of the metal, the Austrian government has restricted the annual production to one hundred and fifty tuns. In 1803, a disastrous fire took place in these mines, which was extinguished only by drowning all the underground workings. The mercury, sublimed by the heat in this catastrophe, occasioned diseases and nervous tremblings in more than nine hundred persons in the neighborhood.

The subterraneous passages of the great mine are so extensive, that it would require several hours to pass through them. The greatest perpendicular depth, computing from the entrance of the shaft, is eight hundred and forty feet; but as these passages advance horizontally, under a high mountain, the depth would be much greater if the measure were taken from the surface. One mode of descending the shaft is by a bucket, but as the entrance is narrow, the bucket is liable to strike against the sides, or to be stopped by some obstacle, so that it may be readily overset. A second mode of descending, which is safer, is by means of a great number of ladders, placed obliquely, in a kind of zigzag: as the ladders, however, are wet and narrow, a person must be very cautious how he steps, to prevent his falling. In the course of the descent, there are several resting-places, which are extremely welcome to the wearied traveler. In some of the subterraneous passages, the heat is so intense as to occasion a profuse sweat; and in several of the shafts the air was formerly so confined, that several miners were suffocated by an igneous vapor, or gaseous exhalation, called the fire-damp. This has been prevented by sinking the main shaft deeper. Near to it is a large wheel, and a hydraulic machine, by which the mine is cleared of water.

To these pernicious and deadly caverns, criminals are occasionally banished by the Austrian government; and it has sometimes happened that this punishment has been allotted to persons of considerable rank and family. The case of Count Alberti is an interesting instance of this kind.

The count, having fought a duel with an Austrian general, against the emperor’s command, and having left him for dead, was obliged to seek refuge in one of the forests of Istria, where he was apprehended, and afterward rescued by a band of robbers who had long infested that quarter. With these banditti he spent nine months, until, by a close investment of the place in which they were concealed, and after a very obstinate resistance, in which the greater part of them were killed, he was taken and carried to Vienna, to be broken alive on the wheel. This punishment was, by the intercession of his friends, changed into that of perpetual confinement and labor in the mines of Idria; a sentence which, to a noble mind, was worse than death. To these mines he was accompanied by the countess, his lady, who belonged to one of the first families in Germany, and who, having tried every means to procure her husband’s pardon without effect, resolved at length to share his miseries, as she could not relieve them. They were terminated, however, through the mediation of the general with whom the duel had been fought, who as soon as he recovered from his wounds, obtained a pardon for his unfortunate opponent; and Alberti, on his return to Vienna, was again taken into favor, and restored to his fortune and rank.

IRON MINES.

The metal which is called iron, is familiar to all, both for its value and its various uses. It is capable of being cast in molds of any form; of being drawn in wires, extended in plates or sheets, of being bent in every direction, and of being sharpened, hardened, or softened at pleasure. It accommodates itself to all our wants, desires, and even caprices; it is equally serviceable to the arts, the sciences, to agriculture, and to war; and the same ore furnishes the sword, the plowshare, the scythe, the pruning-hook, the needle, the graver, the spring of the watch or that of the carriage, the chisel, the chain, the anchor, the compass, the cannon, the bomb, the edge of the finest knife or razor, and the ponderous trip-hammer of enormous weight. It is a medicine of much virtue, and the only metal which is always useful, and tends to no injury to mankind.

The ores of iron are scattered over the entire crust of the globe in beneficent profusion, and in proportion to the utility of the metal itself: they are found in every latitude and zone, in every mineral formation, and in every soil and clime. These ores are nineteen in number, ten of which are worked to profit by the miner, either for the sake of the iron they contain, for use in their native state, or for

extracting from them some principle or material, useful in manufactures or the arts.

Native iron, the existence of which was formerly questioned, has been found in several places: it is, however, far from being common, though it occurs in several mines. A mass of this description of iron was discovered in the district of Santiago del Estero, in South America, by a party of Indians, in the midst of a widely extended plain. It projected about a foot above the ground, nearly the whole of its upper surface being visible; and the news of its having been found in a country where there are not any mountains, nor even the smallest stone, within the circumference of a hundred leagues, was considered as truly surprising. Although the journey was attended with great danger, on account of the want of water, and abundance of wild beasts in these deserts, several individuals, in the hope of gain, undertook to visit this mass; and, having accomplished their journey, sent a specimen of the metal to Lima and Madrid, where it was found to be very pure soft iron.

As it was reported that this mass was the extremity of an immense vein of the metal, a metallurgist was sent to examine the spot, and by him it was found buried in pure clay and ashes. Externally it had the appearance of very compact iron, but was internally full of cavities, as if the whole had been formerly in a liquid state. This idea was confirmed by its having, on its surface, the impression of human feet and hands of a large size, as well as that of the feet of a description of large birds, very common in South America. Although these impressions seemed very perfect, it was concluded either that they were =lusus naturæ=, or that impressions of this kind were previously on the ground, and that the liquid mass of iron, in falling on it, received them. It had the greatest resemblance to a mass of dough; which, having been stamped with impressions of hands and feet, and marked with a finger, had afterward been converted into iron.

On digging round the mass, the under surface was found covered with a coat of scoriæ from four to six inches thick, undoubtedly occasioned by the moisture of the earth, the upper surface being clean. No appearance of the formation of iron was observed in the earth, below or round it, for a great distance. About two leagues to the eastward was a brackish mineral spring, and a very gentle ascent of from four to six feet in hight, running from north to south: with this exception, the adjacent territory was a perfect level. About the spring, as well as near the mass, the earth was very light, loose, and greatly resembling ashes, even in color. The grass in the vicinity was very short, small, and extremely unpalatable to the cattle; but that at a distance was long, and extremely grateful to them. From these concurrent circumstances it was concluded, that this mass of native iron, which was estimated to weigh about three hundred quintals, was produced by a volcanic explosion. It is stated as an undoubted fact, that in one of the forests of the above district of Santiago del Estero, there exists a mass of pure native iron, in the shape of a tree with its branches. At a little depth in the earth are found stones of quartz, of a beautiful red color, which the honey-gatherers, the only persons who frequent this rude territory, employ as flints to light their fires. Several of these were selected on account of their peculiar beauty, they being spotted and studded, as it were, with gold: one of them, weighing about an ounce, was ground by the governor of the district, who extracted from it a dram of gold.

A fibrous kind of native iron has been found at Ebenstock, in Saxony, and also in Siberia, where one particular mass weighed sixteen hundred pounds. It resembled forged iron in its composition, and was malleable when cold, but brittle when red-hot. In Senegal, where it is most common, it is of a cubical form, and is employed by the natives in the manufacture of different kinds of vessels. Native meteoric iron, called also nickeliferous, from its containing nickel, and native steel iron, which has many of the characters of cast steel, have also been found.

Iron, although one of the imperfect metals, is susceptible of a very high polish, and more capable than any other metal of having its hardness increased or diminished by certain chemical processes. It is often manufactured in such a way as to be _one hundred and fifty times_, and, as will now be seen, in some cases, to be even above _six hundred and thirty times_ more valuable than gold. On weighing several common watch-pendulum springs, such as are sold for ordinary work by the London artists, at half a crown, ten of them were found to weigh but one single grain. Hence one pound avoirdupois, equal to seven thousand grains, contains ten times that number of these springs, which amount, at half a crown each, to eight thousand, seven hundred and fifty pounds sterling. Reckoning the troy ounce of gold at four pounds sterling, and the pound equal to fifty-seven hundred and sixty grains, at forty-eight pounds sterling, the value of an avoirdupois pound of gold is over fifty-eight pounds sterling. The above amount of the value of the watch-springs weighing an avoirdupois pound, being divided by that sum, will give a ratio of somewhat more than one hundred and fifty to one. But the pendulum-springs of the best kind of watches sell at half a guinea each; and at this price the above-mentioned value is increased in the ratio of four and one-fifth to one; which gives an amount of thirty-six thousand, seven hundred and fifty pounds sterling. This sum being divided by the value of the avoirdupois pound of gold, gives a quotient of more than six hundred and thirty to one.

It is one of the valuable properties of iron, after it is reduced into the state of steel, that, although it is sufficiently soft when hot, or when gradually cooled, to be formed without difficulty into various tools and utensils, still it may be afterward rendered more or less hard, even to an extreme degree, by simply plunging it, when red-hot, into cold water. This is called tempering, the hardness produced being greater in proportion as the steel is hotter and the water cooler. Hence arises the superiority of this metal for making mechanics' instruments or tools, by which all other metals, and even itself, are filed, drilled and cut. The various degrees of hardness given to iron, depend on the quantity of ignition it possesses at the moment of being tempered, which is manifested by the succession of color exhibited on the surface of the metal, in the progress of its receiving the increasing heat. These are, the yellowish white, yellow, gold-color, purple, violet, and deep blue; after the exhibition of which the complete ignition takes place. These colors proceed from a kind of scorification on the surface of the heated metal.

The largest iron-works in England are carried on in Colebrookdale, in Shropshire. This spot, which is situated between two towering and variegated hills, covered with wood, possesses peculiar advantages, the ore being obtained from the adjacent hills, the coals from the vale, and abundance of limestone from the quarries in the vicinity. The romantic scenery which nature here exhibits, and the works which are carried on, seem to realize the ancient fable of the Cyclops. The noise of the forges, mills, &c., with all their vast machinery, the flames bursting from the furnaces, with the burning coal, and the smoke of the lime-kilns, are altogether horribly sublime. To complete the peculiarities of the spot, a bridge, entirely constructed of iron, is here thrown over the Severn. In one place it has parted, and a chasm is formed; but such is its firm basis, that the fissure has neither injured its strength nor utility.

The great superiority of Swedish iron over that of all other countries, for the manufacture of steel, is well known, and is ascribed to the great purity of the ore from which the iron is smelted. The British steel-makers have found it difficult to employ British iron in their processes, it being too brittle to bear cementation; but attempts have been made at Sheffield, with some success. Wootz, a species of steel from India, has been successfully used for nicer kinds of cutlery. One of the most remarkable of the Swedish mines, if the name can with propriety be applied to it, is Tabern, a mountain of a considerable size, composed entirely of pure iron ore, and occurring in a large tract of sand, over which it seems to have been deposited. This mountain has been wrought for nearly three centuries, notwithstanding which its size is scarcely diminished.

But the richest iron mine of Sweden is that of Danmora, in the province of Upland. It is in depth eighty fathoms; occupies a considerable extent of territory; and its ore is conveyed to the surface of the earth, through several pits or openings made for that purpose, by means of casks fixed to large cables, which are put in motion by horses. The workmen standing on the edges of these casks, and having their arms clasped round the cable, descend and ascend with the utmost composure. The water is drawn from the bottom by a wheel sixty-six feet in diameter, and is afterward conveyed along an aqueduct nearly a mile and a half in length. At certain distances from Danmora, are several furnaces, with large and populous villages exclusively inhabited by the miners.

In Wraxall's tour through the north of Europe, the mine of Danmora is described as yielding the finest iron ore in Europe, its produce being exported to every country, and constituting one of the most important sources of national wealth and royal revenue. The ore is not dug, as is usual in other mines, but is torn up by the force of gunpowder, an operation which is performed every day at noon, and is one of the most awful and tremendous that can possibly be conceived. "We arrived," observes the tourist, "at the mouth of the great mine, which is nearly half an English mile in circumference, in time to be present at it. Soon after twelve the first explosion took place, and could not be so aptly compared to anything as to subterraneous thunder, or rather volleys of artillery discharged under ground. The stones were thrown up, by the violence of the gunpowder, to a vast hight above the surface of the ground, and the concussion was so great as to shake the surrounding earth or rock on every side.

"As soon as the explosion had ceased, I determined to descend into the mine, to effect which I had to seat myself in a large, deep bucket, capable of containing three persons, and fastened by chains to a rope. When I found myself thus suspended between heaven and earth by a rope, and looked down into the dark and deep abyss beneath me, to which I could see no termination, I shuddered with apprehension, and half repented my curiosity. This was, however, only a momentary sensation, and before I had descended a hundred feet, I looked round on the scene with very tolerable composure. It was nearly nine minutes before I reached the bottom; and when I set my foot on the earth, the view of the mine was awful and sublime in the highest degree. Whether, as I surveyed it, terror or pleasure formed the predominant feeling, is hard to say. The light of the day was very faintly admitted into these subterraneous caverns: in many places it was absolutely lost, and flambeaux were kindled in its stead. Beams of wood were laid across some parts, from one side of the rock to the other; and on these the miners sat, employed in boring holes for the admission of gunpowder, with the most perfect unconcern, although the least dizziness, or even a failure in preserving their equilibrium, must have made them lose their seat, and have dashed them against the rugged surface of the rock beneath. The fragments torn up by the explosion, previously to my descent, lay in vast heaps on all sides, and the whole scene was calculated to

inspire a gloomy admiration.

“I remained three-quarters of an hour in these frightful and gloomy caverns, which find employment for not less than thirteen hundred workmen, and traversed every part of them which was accessible, conducted by my guides. The weather above was very warm, but here the ice covered the whole surface of the ground, and I found myself surrounded with the colds of the most rigorous winter, amid darkness and caves of iron. In one of these, which ran a considerable way beneath the rock, were eight wretched beings warming themselves round a charcoal fire, and eating the little scanty subsistence arising from their miserable occupation. They rose with surprise at seeing so unexpected a guest among them, and I was not a little pleased to dry my feet, which were wet with treading on the melted ice, at their fire.

“Having gratified my curiosity with a view of these subterraneous apartments, I made the signal for being drawn up, and felt so little terror while reascending, compared with that of being let down, that I am convinced, after five or six repetitions, I should have been perfectly indifferent to the undertaking. So strong is the effect of custom on the human mind, and so contemptible does danger or horror become when familiarized by repeated trials!”

Throughout the whole extent of Sweden, the iron mines at present wrought, employ thousands of persons, and yield annually upward of one hundred thousand tuns of metal. There are said to be between five and six hundred mines in the entire country, nearly half of which are situated in the central provinces: this, however, includes mines of all descriptions, though by far the most are of iron. The products of all these mines would be vastly greater than they are, were it not for the multiplied and unreasonable restrictions of the government.

The iron trade of the United States, and the domestic manufacture of iron, were spoken of by Mr. Gallatin, in a report to Congress, in 1810, as being firmly established. He was able to obtain very imperfect information about it, but it was known that iron ore was plentiful; that numerous forges and furnaces had been erected, supplying “a sufficient quantity of hollow-ware, and of castings of every description.” From Russia, about forty-five hundred tuns of bar iron were imported yearly, and perhaps another forty-five hundred from Sweden and England. A vague estimate gave fifty thousand tuns of bar iron as the annual consumption of the union, of which he considered forty thousand as the product of the republic. Some good iron was made in Virginia and Pennsylvania, but much inferior iron, carelessly manufactured, was brought into market. Of sheet, slit, and hoop iron, about five hundred and sixty-five tuns were annually imported; about seven thousand tuns were rolled and slit in the United States. Massachusetts had thirteen rolling and slitting mills, and the value of cut nails and brads made within the republic in a year, was estimated at twelve hundred thousand dollars. Nearly three hundred tuns of cut nails were exported. Agricultural implements were made at home, and much coarse ironmongery; but cutlery, fine hardware, and steel work, were brought from Britain. About forty thousand muskets were yearly made in New England and at Harper’s Ferry: also balls, shells, and brass and iron cannon, in various places. There were several iron founderies for machinery castings, and steam-engines had begun to be made at Philadelphia. Mr. Gallatin valued the iron and manufactures of iron then annually made at home, at from twelve to fifteen millions of dollars, and the imports at near four millions, as prices went.

Adam Seybert enumerates the domestic products of 1810, at 53,908 tuns of pig iron, from 153 furnaces; 24,541 tuns of bar iron from 330 forges; 15,727,914 pounds of nails (partly out of imported iron) from 410 naileries; and 6,500 tuns of iron were required at 316 trip-hammers and thirty-four rolling and slitting mills. His estimate of the value of the home manufacture is $14,364,526. In 1806 or 1807, Chancellor Livingston, then our minister to France, had to apply repeatedly to the British ministry for permission to buy in England, and export to New York, the steam-engine which Fulton put on board his first steamboat on the Hudson. Now, the manufacture of steam-engines is an important branch of our home industry.

In 1827-8, it was given in evidence before a committee of Congress, that Pennsylvania had made, during the past year, 21,800 tuns of bar iron, and 47,075 tuns of cast iron; that 3,000 tuns of bar iron were made near Lake Champlain; that three counties in New Jersey had made 2,050 tuns, and that in a circle of thirty miles’ diameter, in New York, there were one hundred and ten forge fires, each of them able to produce twenty-five to thirty-five tuns yearly. In 1830, a committee of Congress reported on the iron trade, and from their report and other later sources, we learn that that year 112,866 tuns of bar, and 191,537 of pig iron, worth $13,327,760, employing 29,254 men, who received $8,776,420 in wages, were made. Perhaps the quantity and number of workmen are overstated. In 1840, with improved machinery, only 30,497 men produced 484,136 tuns.

Without coal and iron, the United States and Britain never could have risen to the rank of first-rate powers. In fact, without iron, civilization must have made very slow progress, as must be evident to any one who will take the trouble to try seriously to

enumerate the various articles _essential_ to society, of which iron is an indispensable part.

In 1839-40, according to the official returns, which are imperfect, the United States produced, with 804 furnaces, 286,903 tuns of cast iron, and with 795 blomaries, forges and rolling-mills, 187,233 tuns of bar iron. The capital invested was nearly twenty and a half millions of dollars; the men employed, miners included, were 30,497, and 1,528,110 tuns of fuel were employed in these operations. The value of iron and steel, and their manufactures, imported in 1839-40, as per official returns, was $7,241,407. The estimated value of the iron made in the United States that year, was $22,778,635; of which sum $15,585,730 were for labor, including mining, transportation, coaling, hauling, &c. The persons employed in the iron manufacture, and their families, were estimated at 213,505, which, at twelve and a half cents each, per day, for agricultural products consumed, would give $9,741,166.

In 1845, the product of the union was estimated thus: 540 blast furnaces, yielding 486,000 tuns of pig iron; 954 blomaries, forges, rolling-mills, &c. yielding 291,600 tuns of bar, hoop, sheet, boiler, and other wrought iron, 30,000 tuns of blooms and 121,500 tuns of castings; value of the whole nearly forty-two millions of dollars.

The United States imported of iron, chiefly bar and bolt, rolled, hammered, or otherwise manufactured, and pig, hoop and sheet, in 1838-9, 115,637 tuns; in 1839-40, 72,769; 1840-1, 112,111; in 1841-2, 107,392; in 1842-3, 38,405.

In 1846-7, we find by the treasury report, that the United States exported of domestic manufactures, 3,197,135 pounds of nails, worth $168,817, of which Cuba took 2,317,550 pounds; also other articles of iron and steel to the value of $998,667, of which $478,681 to Cuba, and $162,020 to British North America. In that year, among the imports, chiefly from England, were 549 tuns of steel, value $1,126,458; 55,599 tuns of bar iron; 28,083 tuns of pig; 1,893 tuns of scraps; 6,167,720 pounds of chain cables; 13,410,556 pounds of sheet and hoop; 1,412,332 pounds of anvils; 921,845 pounds of nails; 361,423 pounds of anchors; 975,256 pounds of castings; 170,909 pounds of cast-iron butts; 431,916 pounds of band; 660,133 pounds of round or square; 347,737 pounds of nail or spike rods.

Official tables show that the imports of manufactures of steel and iron in 1839, were worth $6,507,510; in 1843, $1,012,086; in 1844, $3,313,796; in 1845, $5,077,788; and that in 1839, the value of pig and bar iron and steel imported was $6,302,539; in 1842 and 1845, nearly four millions each year; in 1843, $1,091,598; and in 1844, $2,380,027.

Some idea of the extent of the iron trade inland may be formed from the quantities carried on the canals. In 1847, there came to the Hudson on the New York canals, pig iron, 21,608,000 pounds; bloom and bar 26,348,000 pounds; iron ware, 3,014,000 pounds: 340 tuns of iron and iron ware were cleared on the canals at Buffalo and Oswego; St. Lawrence county, N. Y., shipped 515 tuns of pig, a surplus made there; 7,716 tuns of pig iron reached Buffalo _via_ Lake Erie, and 1,256 kegs of nails; 15,103,565 pounds of iron and nails arrived at Cleveland _via_ the Ohio canal, and 4,085 tuns of iron and 12,537 kegs of nails were shipped from Cleveland coastwise. There were cleared at Portsmouth, Chilicothe, Massillon, and Akron, in 1847, about 5,713 tuns of iron; 5,269,055 pounds of nails were shipped at Akron. The trade in coal and iron on the western rivers and lakes is very large.

Iron canal-boats were in common use in Wales thirty years ago: they are beginning to be made here; also war-steamers. Fences, and even porches to houses, are often of iron. The pipes for the Croton water in New York required many thousand tuns. The annual value of 150,000 tuns of iron ore of Maryland is worth $600,000 at Baltimore. A single foundery in Tennessee sold, in 1844, of sugar-kettles, $50,000 worth.

Child's statistics show that in Pennsylvania, in 1847, there were made, at 213 furnaces, 98,395 tuns of cast iron, and at 169 blomaries, forges, &c., 87,244 tuns of bar iron, 11,522 men being employed, including limestone miners, and a capital of $7,751,470 invested. In 1846, there were 173,369 tuns manufactured, seven of the furnaces using anthracite coal. Forty furnaces, in 1847, were in blast, using anthracite, and producing 121,800 tuns of iron, at a reduced price, which price had induced capitalists to put up extensive rolling-mills. The American Quarterly Register has a list of nineteen anthracite rolling-mills in Pennsylvania, which make iron rails and plate, bar and rod, nails, axle and small iron.

The first bar of railroad iron ever manufactured in the United States, was made in 1841, and now it is said, one hundred thousand tuns could be made easily; while the annual product of iron from all the furnaces, which are said to be some three hundred in number, is estimated at over four hundred thousand tuns.

The yearly manufacture of iron in Great Britain, is now estimated at nearly three millions of tuns. In 1828, there were in Russia, nineteen founderies, forges and mines, and in 1804, that country exported to America over nine million pounds of iron. In 1819, France produced seventy-four million pounds of iron, and in 1845, this had increased to three hundred and forty-two millions, or

over one hundred and fifty thousand tuns. Of iron and steel, and the various manufactures from them, Great Britain exported in 1845, to the extent of thirty-three millions.

COPPER MINES.

Copper (from =cuprum=, a corruption of =cuprium=, from the island of Cyprus, whence it was formerly brought) was known at a very remote period; and in the early ages of the world, before iron was extensively in use, was the chief ingredient in domestic utensils and instruments of war. It is abundant; and is found both native and in many ores, the most important of which are the varieties of _pyrites_, which are sulphurets of copper and iron. The genus copper includes some thirteen species, and each of these contains several varieties.

The purest copper obtained in Europe, is the produce of the mines of the Swedish province of Dalecarlia. The following is a brief description of the principal of these immense and gloomy caverns, all of which boast a high antiquity.

The traveler's curiosity is first attracted by the hydraulic machines which convey the water to the different quarters, and the power of which is such, that one of the wheels has a diameter of not less than forty-four feet. Another wheel, of proportionate magnitude, is employed to raise the ore from the mine to the surface of the earth, and is admirably constructed. Regular circles are placed on each side, and round these the chain rises, taking a larger or smaller circumference, in proportion to the necessary circle to be made, so as to counterbalance the weight, and consequently the increased motion of the bucket.

Exteriorly, a vast chasm of a tremendous depth presents itself to the view. This being the part of the mine which was first opened, either through the ignorance or neglect of those who had then the management of the works, the excavations so weakened the foundations of the hill, that the whole fell in, leaving a most chaotic scene of precipitated rocks, and a gaping gulf resembling the mouth of a volcano. Great care has been since taken that no such disaster should again occur. Plans and sections are drawn of all the galleries, &c.; and where the prosecution of the works in the same direction might be dangerous, orders are issued for the miners to stop, and an iron crown is fixed on the spot, as a prohibition ever to proceed further. The workmen then explore in a different direction, while every subterraneous excavation is nicely watched.

The traveler passes into the great chasm by a range of wooden steps, which cross, in a variety of directions, the rough masses of fallen rocks, of gravel, and of the ancient machinery. Ere he reaches the entrance of the cavern, he has to descend nearly two hundred feet, and this being accomplished, proceeds horizontally to a considerable distance within. He now loses the pure air of day, and gradually breathes an oppressive vapor, which rolls toward him, in volumes, from the mouths of a hundred caves leading into the main passage. He now feels as if he were inhaling the atmosphere of Tartarus. The Swedish iron mines which have been described, are mere purgatories when compared with this satanic dwelling. The descent is performed entirely by steps laid in the winding rock; and, in following the subterraneous declivity, the traveler reaches the tremendous depths of these truly Stygian dominions.

The pestilential vapors which environ him with increasing clouds, and the style of the entrance, remind him of Virgil's description of the descent of Eneas to the infernal regions. Here are to be seen the same caverned portico, the rocky, rough descent, and the steaming sulphur, with all the deadly stenches of Avernus. The wretched inmates of this gloomy cavern, appear to him like so many specters, as poetic fiction has described them: and he is induced by the length of the way, joined to the excessive heat and its suffocating quality, to fancy that he will be made to pay dearly for his curiosity. In one part the steam is so excessively hot, as to scorch at the distance of twelve paces, at the same time that the sulphureous smell is intolerable. Near this spot a volcanic fire broke out some years ago, in consequence of which strong walls were constructed, as barriers to its power, and several contiguous passages, which, had it spread, would have proved dangerous to the mine, closed up.

The visitor has now to traverse many long and winding galleries, as well as large vaulted caverns, where the workmen are dispersed on all sides, employed in hewing vast masses of the rock, and preparing other parts for explosion. Others wheel the brazen ore toward the black abyss, where the suspended buckets hang ready to draw it upward. From the effect of such violent exercise, combined with the heat, they are obliged to work almost naked. Their groups, occupations, and primitive appearance, scantily lighted by the trembling rays of torches, form a curious and interesting scene.

The depth of the mine being at least twelve hundred feet, a full hour is required to reach to the bottom. The mass of copper lies in the form of an inverted cone. Five hundred men are employed daily; but females are not admitted, on account of the deleterious quality of the vapors. This mine was anciently a state prison, in which criminals, slaves and prisoners of war toiled out their

wretched existence. Near the bottom is a rocky saloon, furnished with benches. It is called the Hall of the Senate, on account of its having been the resting-place of several Swedish kings, who came, attended by the senators, to examine the works, and here took refreshments. It was in this mine that the immortal Gustavus Vasa, disguised as a peasant, labored for his bread, during a long concealment, after having been robbed by his guide; and his first adherents in the struggle which placed him on the throne, were from the miners and peasants of Dalecarlia.

In the year 1751, a very rich copper mine was wrought in the county of Wicklow, Ireland. From this mine ran a stream of blue-colored water, of so deleterious a nature as to destroy all the fish in the river Arklow, into which it flowed. One of the workmen, having left an iron shovel in this stream, found it some days after incrusted with copper. This led one of the proprietors of the mine to institute a set of experiments, from which he concluded that the blue water contained an acid holding copper in solution; that iron had a stronger affinity for the acid than copper; and that the consequence of this affinity was the precipitation of the copper, and the solution of the iron, when pieces of that metal were thrown into the blue water. These ideas induced the miners to dig several pits for the reception of this water, and to put bars of iron into them. The result was, that they obtained an abundance of copper, much purer and more valuable than that which they had procured from the ore itself by smelting.

On the island of Anglesea, near Dulas bay, on the north coast, is Parys mountain, which contains the most considerable quantity of copper ore perhaps ever known. The external aspect of the hill is extremely rude, and it is surrounded by enormous rocks of coarse white quartz. The ore is lodged in a basin, or hollow, and has on one side a small lake, over the waves of which, as over those of Avernus, fatal to the feathered tribe, it is said that birds are never known to pass. The effect of the mineral operations has been, that the whole of this tract has assumed a wild and savage appearance. Suffocating fumes of the burning heaps of copper arise in all parts, and extend their baneful influence for miles around. That the ore was worked in a very remote period, appears by vestiges of the ancient operations, which were carried on by trenching, and by heating the rocks intensely, when water was suddenly poured on them, so as to cause them to crack or scale. In the year 1768, after a long search, which was so little profitable that it was on the eve of being abandoned, a large body of copper ore was found; and this has ever since been worked to great advantage, still promising a vast supply. The water lodged in the bottom of the bed of ore, being strongly impregnated with the metal, is drawn up and distributed in pits, where the same process is employed as in the Wicklow mine. The copper thus procured differs little from native copper, and is very highly prized.

In the Parys mine, eight tuns of gunpowder are annually expended in blasting the rock. Nature has here been profuse in bestowing her mineral favors; for, above the copper ore, and not more than two feet beneath the soil, is a bed of yellowish greasy clay, from three to twelve feet in thickness, containing lead ore, from a tun of which metal, upward of fifty ounces of silver are generally obtained.

[Illustration: COPPER MINE IN CORNWALL.]

The copper mines of Cornwall, a view of one of which is given in the cut, are very numerous, and several of them large and very rich in ore. It is remarkable that in various parts of this country the earth has produced such an exuberance of this metal, as to afford it in large massy lumps of malleable copper, several pieces of which are shown in very curious vegetable forms. The particular ore named _mundic_, found in the tin mines, was for many ages considered of no other use but to nourish that metal while in the mine. In the reign of Queen Elizabeth, a laudable curiosity tempted several private individuals to examine into its nature; but the design miscarried, and the mundic was thrown, as useless, into the old pits in which the rubbish was collected. However, about a century ago, this purpose was effected by degrees; and the copper extracted from the ore now produces, on an average, upward of twelve thousand tuns, valued at between four and five millions of dollars, annually, equaling in goodness the best Swedish copper, while the ore itself yields a proportionate quantity of =lapis calaminaris=, for the making of brass.

At Ecton hill, near the river Dove, in Derbyshire, a valuable copper mine was discovered some years ago, and has since been worked to great advantage. In its position, situation and inclination, it differs from any mine yet discovered in Europe, Asia, Africa or America; the wonderful mass of copper ore not running in regular veins or courses, but sinking perpendicularly down, widening and swelling out at the bottom in the form of a bell. The works are four hundred and fifty feet beneath the river Dove, it being the deepest mine in Great Britain. On the opposite side of Ecton hill is a valuable lead mine, the veins of which approach very nearly to the copper mine.

Copper is converted into brass by the agency of calamine, an oxyd of zinc. It occurs frequently in beds, and in some places exists in great abundance. The Mendip hills, in Somersetshire, were once celebrated for their mines of calamine, which are now in a great

measure exhausted. It is dug out of the earth, and being broken into small pieces, is exposed to the action of a current of water, which washes away the light earthy matter, and leaves the calamine. The whole is then thrown into deep wooden vessels filled with water, and agitated for a considerable time. The galena sinks to the bottom, the calamine is deposited in the center, and the earthy matter lies on the surface. The calamine, thus separated from its impurities, is ground to powder, and becomes fit for use.

Hungary abounds in valuable ores and minerals, and is most celebrated for its vast copper works, at a town called Herrengrund, built on the summit of a mountain, and exclusively inhabited by miners. Here the process, noticed above, of apparently converting iron into copper, is pursued with great success, several hundred weight of iron being thus transmuted every year. The vitriol, with which the blue water is strongly impregnated, can not be strictly said to convert the iron into copper, but insinuates into it the copper particles with which it is saturated; and this seeming transmutation requires a fortnight or three weeks only: but if the iron be suffered to lie too long in this vitriolic solution, it becomes at length reduced to powder.

In Japan, copper is the most common of all the metals, and is considered as the finest and most malleable anywhere to be found. Much of this copper is not only of the purest quality, but is blended with a considerable proportion of gold, which the Japanese separate and refine. The whole is brought to Saccin, one of the five principal cities of Japan; and it is there purified, and cast into small cylinders, about a span and a half in length, and a finger's breadth in thickness. Brass is there very scarce, and much dearer than copper, the calamine employed in making it being imported from Tonquin in flat cakes, and sold at a very high price.

In addition to the copper mines thus described, copper has, within a few years, been found in the richest abundance in the vicinity of Lake Superior. The existence of copper there, was, indeed, known as early as 1636; and the trace of these early discoveries was never entirely lost. But the first scientific researches were made in 1842, by Dr. Douglas Houghton, who was acting as geological surveyor for the state of Michigan. According to his report, native copper exists in two or three different deposits about Lake Superior, where it is found in the richest abundance, both in veins and in large masses in the native state. Dr. Jackson also states, that he has seen one of these masses, twenty feet long, nine feet wide, and from four to six inches in thickness, and weighing about twenty tuns. He adds, that in a single year, thirty-three men, of whom only twenty were properly miners, had taken out forty-three tuns of ore, yielding thirty tuns of pure copper. Among the masses of copper obtained from these mines as early as 1848, were four, the weights of which, respectively, were seven thousand and eighteen, seven thousand four hundred and eighty-four, seven thousand six hundred and seventy-eight, and fourteen thousand pounds. Since that date new openings have been made; new mining companies formed, and the products of the mines very greatly increased: and it may yet be, that these mines will prove some of the richest and most valuable of the world.

TIN MINES.

Tin, in its pure state, has nearly the color and luster of silver. In hardness, it is midway between gold and lead. It was known to the ancients, who procured it from Spain and Britain, and appears to have been in use in the time of Moses. It is rather a scarce metal, being found in but few parts of the world in any considerable quantity. Cornwall is its most productive source; it also occurs in the mountains between Gallicia and Portugal, and in those between Saxony and Bohemia. It has, also, been brought from Malacca, in India, and from Chili and Mexico. There are but two ores of tin; one of which, the native peroxyd, is the chief source of all the supplies of this metal, as the other ore, which is the double sulphuret of tin and copper, sometimes called _bell-metal ore_, is extremely rare.

Cornwall has been in all ages, famous for its numerous mines of tin, which are in general very large, and rich in ore. The tin-works are of different kinds, dependent on the various forms in which the metal appears. In many places its ore so nearly resembles common stones, that it can only be distinguished from them by its superior weight. In other parts, the ore is a compound of tin and earth, concreted into a substance almost as hard as stone, of a bluish or grayish color, and to which the mundic, impregnated with copper, frequently gives a yellowish cast. This ore is always found in a continued stratum, which the miners call lode; and this, for the greater part, is found running through the solid substance of the hardest rocks, beginning in small veins near the surface, perhaps not above half an inch or an inch wide, and increasing, as they proceed, into large dimensions, branching out into several ramifications, and bending downward in a direction which is, generally, nearly east and west. These lodes, or veins, are sometimes white, very wide, and so thick, that large lumps of the ore are frequently drawn up of more than twenty pounds' weight. The lodes of tin ore are not always contiguous, but sometimes break off so entirely, that they seem to terminate; but the sagacious miner knows by experience, that, by digging at a small distance on one side, he will meet with a separated part of the lode, apparently tallying with the other end, as nicely as if it had been broken off by some sudden shock of the rock.

The miners of Cornwall follow the lode, or vein, in all its rich and meandering curves through the bowels of the flinty earth. The waters are sometimes drained from the mines, by subterraneous passages, formed from the body of the mountain to the level country. These passages are called _adits_, and are occasionally the labor of many years; but when effected, they save the constant expense of large water-works and fire-engines. From the surface of the earth the workmen sink a passage to the mine, which they call a shaft, and place over it a large winch, or, in works of greater magnitude, a wheel and axle, by which means they draw up large quantities of ore at a time, in vessels called _kibbuls_. This ore is thrown into heaps, which great numbers of poor people are employed in breaking to pieces, and fitting the ore for the stamping-mills.

A third form in which tin appears is that of crystals; for this metal will, under proper circumstances, readily crystallize. Hence, in many parts of the mineral rocks, are found the most perfectly transparent and beautiful crystals of pure tin. Beside these crystals, in many of the cavernous parts of the rocks, are found those transparent crystals, called Cornish diamonds, they being extremely brilliant when well polished. The form is that of a six-sided prism pointed on the top, and they are sometimes four or five inches in length. The value of the tin exported from Great Britain, in 1853, the greater part of which came from the Cornwall mines, was nearly six million dollars.

LEAD MINES.

Lead is one of the metals most anciently known, being mentioned in the books of Moses. It is found in some thirteen species of ore, only one of which (_galena_) occurs in masses sufficiently large to make it valuable as an object of mining and metallurgy. The uses of lead are so familiar that they need not be mentioned: they are known to all.

Among the most remarkable lead mines of the world, may be mentioned those of the state of Illinois, including also parts of Iowa and Wisconsin, which have been, and still are immensely productive, extending over thousands of acres, and furnishing the mineral in the richest abundance. These mines were formerly known as the mines of “Upper Louisiana.” They are now chiefly worked in the vicinity of Galena, a city which has sprung up, and is almost entirely supported by the trade in lead. So vast is the production of these mines, that forty million pounds of lead, valued at sixteen hundred thousand dollars, were shipped from Galena alone, in 1853. The mineral in one of the earliest opened mines, is said to be of two kinds, the gravel and fossil. The gravel mineral is found immediately under the soil, intermixed with gravel, in pieces of solid mineral weighing from one to fifty pounds. Beneath the gravel is a sand rock, which being broken, crumbles to a fine sand, and contains mineral nearly of the same quality as that of the gravel. But the mineral of the first quality is found in a bed of red clay, under the sand rock, in pieces of from ten to five hundred pounds’ weight, on the outside of which is a spar, or fossil, of a bright, glittering appearance, resembling spangles of gold and silver, as solid as the mineral itself, and of a greater specific gravity. This being taken off, the mineral is solid, unconnected with any other substance, of a broad grain, and what mineralogists call potters’ ore. In other mines, in the vicinity of the above, the lead is found in regular veins, from two to four feet in thickness, containing about fifty ounces of silver in a tun.

In Great Britain, there are numerous and exceedingly valuable lead mines, among which may be cited that of Arkingdale, in Yorkshire, and those with which Shropshire abounds. In the south of Lanarkshire, and in the vicinity of Wanlock-head, Scotland, are two celebrated lead mines, which yield annually above two thousand tuns of metal. The Susannah-vein lead-hills, have been worked for many years, and have been productive of great wealth. The above are considered as the richest lead mines of Europe.

Several of the Irish lead mines have yielded a considerable proportion of silver; and mention is made of one, in the county of Antrim, which afforded, in thirty pounds of lead, a pound of that metal. Another, less productive of silver, was found at Ballysadare, near the harbor of Sligo, in Connaught; and a third in the county of Tipperary, thirty miles from Limerick. The ores of this last were of two kinds, most usually of a reddish color, hard and glittering; the other, which was the richest in silver, resembled a blue marl. The works were destroyed in the Irish insurrections in the reign of Charles I. The mine, however, is still wrought on account of the lead it contains.

COAL MINES.

Coal is one of the most valuable of all mineral treasures, and one that is of the highest service in making the others available to the use and comfort of man. And hence it has been searched after with unremitting diligence, and worked with all the lights of science and the resources of art. It is found in beds or strata, in that group of the secondary rocks which includes the red sandstone and mountain limestone formations, commonly called the _carboniferous group_, or the _coal measures_. From the peculiarities of their position, they are often spoken of as _coal-basins_, and _coal-fields_.

There are two or three points of some theoretical interest and importance as to the origin of coal, on which geological authorities are nearly unanimous. One is, that our present coal is exclusively of vegetable origin, formed apparently from the destruction of vast forests and immense quantities of leaves and shrubs; another, that it was formed when the climate of the regions where it is found was not merely tropical, but ultra-tropical, instead of being as now, temperate; and a third, that its deposits, though originally regular, have evidently been since elevated, and often singularly dislocated and contorted by forces acting from below, and probably of a volcanic nature. Each of these points will more or less appear in the progress of the following remarks.

That the coal formations are of vegetable origin, is perfectly evident from even a slight examination, especially with the microscope. Let a piece of coal be cut in very thin slices, or plates, and its appearance will be like that seen in the following cut. The vegetable fossils thus shown are, indeed, very different from any existing species, unless it be a few which are the productions only of torrid climates. And while the cut gives the appearance of but a _single leaf_ in each specimen, the masses of coal are generally more like one thick imbedded mass of leaves, not so much _crushed together_, as _overlaying_ and _mixed with_ each other. According to Dr. Linley, the coal vegetation consisted of ferns, in great abundance; of large coniferous trees, of a species resembling =lycopodiacæ=, but of most gigantic dimensions; of a numerous tribe apparently analogous to =cactæ=, but probably not identical with them; of palm, and other _monocotyledones_; and finally, of numerous vines, plants, &c., the exact nature of which is uncertain. Where _leaves_ most abound, the coal is said to be of the best quality; though as any one kind of coal hardens, the impressions of such leaves become gradually less distinct, until finally they can hardly be traced, even with a powerful magnifier. A hundred and twenty varieties of these vegetable impressions have been found in the vicinity of Pottsville, in the course of a few months, each as distinctly marked as the most delicate tracings of an artist's pencil; and in almost any coal formation, there are so many hundreds of different plants, trees, and flowers, that a single representative of each kind would form a vast museum. Specimens which exhibit impressions of the bark, limbs, or trunks of trees, are, of course, correspondingly large and heavy, and could not easily be sketched in a small engraving, while the variety of leaves and flowers is so great, that it would be tedious to mention and describe them.

[Illustration: THIN PLATES OF COAL.]

With these few remarks, we proceed to notice first, some of the coal mines of Great Britain, and then some of our own country. Perhaps there is no country where coal mines are so rich, so frequent, and so successfully worked thus far, as those of Great Britain; and it is to this cause that the opulence of that country has often been chiefly ascribed. It is, in truth, the coal of her mines, that is the very life of her manufactures, and consequently of her commerce, every manufacturing town being established in the midst of a coal country. Of this striking instances are afforded by Bristol, Birmingham, Wolverhampton, Sheffield, Newcastle, and Glasgow.

The coals of Whitehaven and Wigan are esteemed the purest; and the cannel and peacock coals of Lancashire are so beautiful, that they are suspected by some to have constituted the _gagates_, or jet, which the ancients ascribed to Great Britain. In Somersetshire, the Mendip coal mines are distinguished by their productiveness: they occur there, as indeed in every other part, in the _low_ country, and are not to be found in the hills. The beds of coal are not horizontal, but sloping, dipping to the south-east at the rate of about twenty-two inches per fathom. Hence they would speedily sink so deep that it would not be possible to work them, were it not that they are intersected at intervals by perpendicular dikes or veins, of a different kind of mineral, on the other side of which these beds are found considerably raised up. They are seven in number, lying at regular distances beneath each other, and separated by beds of a different kind of substance, the deepest being placed more than two hundred feet beneath the surface of the earth.

The town of Newcastle, in Northumberland, has been celebrated during several centuries for its very extensive trade in coal. It was first made a borough by William the Conqueror, and the earliest charter for digging coals, granted to the inhabitants, was in the reign of Henry III., in 1239; but in 1306, the use of coal for fuel was prohibited in London, by royal proclamation, chiefly because it injured the sale of wood, with which the environs of the capital were then overspread. This interdict did not, however, continue long in force; and coals may be considered as having been dug for exportation at Newcastle for more than four centuries. It has been estimated that there are twenty-four considerable collieries lying at different distances from the river, from five to eighteen miles; and that they produced, for an average of six years, up to the close of 1776, an annual consumption of three hundred and eighty thousand chaldrons, Newcastle measure, (equal to seven hundred and seventeen thousand, six hundred and fifteen chaldrons, London measure,) of which about thirty thousand chaldrons were exported to foreign parts. The boats employed in the colliery are called _keels_, and are described as strong, clumsy, and oval, each carrying about twenty tuns; and of these four hundred and fifty are kept constantly employed. In the year 1776 an estimate was made of the shipping employed in the Newcastle coal trade; and

from this estimate it appears, that three thousand, five hundred and eighty-five ships, were during that year engaged in the coasting trade, and three hundred and sixty-three in the trade to foreign ports, their joint tunnage amounting to seven hundred and thirty-eight thousand, two hundred and fourteen tuns.

As already said, it is a common opinion among geologists, that coal is of vegetable origin, and that it has been brought to its present state by the means of some chemical process, not at this time understood. This opinion is abundantly supported by the existence of vast depositions of matter, halfway, as it were, between perfect wood and perfect coal; which, while it obviously betrays its vegetable nature, has in several respects so near an approximation to coal, as to have been generally distinguished by the name of coal. One of the most remarkable of these depositions exists in Devonshire, about thirteen miles south-west of Exeter, and is well known under the name of Bovey coal. Its vegetable nature has been ascertained by Mr. Hatchet, in a set of experiments in which he found both extractive matter and resin, substances which belong to the vegetable kingdom.

The beds of this coal are seventy feet in thickness, and are interspersed with beds of clay. On the north side they lie within a foot of the surface, and dip south at the rate of about twenty inches per fathom. The deepest beds are the blackest and heaviest, and have the closest resemblance to coal, while the upper ones strongly resemble wood, and are considered as such by those who dig them. They are brown, and become extremely friable when dry, burning with a flame similar to that of wood, and assuming the appearance of wood which has been rendered soft by some unknown cause, and, while in that state, has been crushed flat by the weight of the incumbent earth. This is the case, not only with the Bovey coal, but also with all the beds of wood-coal which have been hitherto examined in different parts of Europe.[5]

Footnote 5:

We are informed by Liebig and other eminent chemists, that when wood and other vegetable matter are buried in the earth, exposed to moisture, and partially or entirely excluded from the air, they decompose slowly, and evolve carbonic acid gas; thus parting with a portion of their original oxygen. By this means they are gradually converted into lignite, or wood-coal, which contains a larger proportion of hydrogen than wood does. A continuance of decomposition changes this lignite into common or bituminous coal, chiefly by the discharge of carbureted hydrogen, or the gas by which we illuminate our streets and houses. According to Birchoff, the inflammable gases which are always escaping from mineral coal, and are so often the cause of fatal accidents in mines, always contain carbonic acid, carbureted hydrogen, nitrogen, and olefiant gas. The disengagement of all these gradually transforms ordinary or bituminous coal into anthracite, to which the various names of splint-coal, glance-coal, culm, and many others, have been given.

The coal mines of Whitehaven may be considered as among the most extraordinary in the known world. They are excavations which have, in their structure, a considerable resemblance to the gypsum quarries of Paris, and are of such magnitude and extent, that in one of them alone, a sum exceeding half a million sterling, was, in the course of a century, expended by the proprietors. Their principal entrance is by an opening at the bottom of a hill, through a long passage hewn in the rock, leading to the lowest vein of coal. The greater part of this descent is through spacious galleries, which continually intersect other galleries, all the coal being cut away, with the exception of large pillars, which, where the mine runs to a considerable depth, are nine feet in hight, and about thirty-six feet square at the base. Such is the strength there required to support the ponderous roof.

The mines are sunk to the depth of one hundred and thirty fathoms, and are extended under the sea to places where there is, above them, sufficient depth of water for ships of large burden. These are the deepest coal mines which have hitherto been wrought; and perhaps the miners have not, in any other part of the globe, penetrated to so great a depth beneath the surface of the sea, the very deep mines in Hungary, Peru and elsewhere, being situated in mountainous countries, where the surface of the earth is elevated to a great hight above the level of the ocean.

In these mines there are three strata of coal, which lie at a considerable distance one above the other, and are made to communicate by pits; but the vein is not always continued in the same regularly inclined plane, the miners frequently meeting with hard rock, by which their further progress is interrupted. At such places there seem to have been breaks in the earth, from the surface downward, one portion appearing to have sunk down, while the adjoining part has preserved its ancient situation. In some of these places the earth has sunk ten, twenty fathoms, and even more; while in others the depression has been less than one fathom. These breaks the miners call _dikes_, and when they reach one of them, their first care is to discover whether the strata in the adjoining part are higher or lower than in the part where they have been working; or, according to their own phrase, whether the coal be _cast down_ or _cast up_. In the former case they sink a pit; but if it be cast up to any considerable hight, they are

frequently obliged, with great labor and expense, to carry forward a level, or long gallery, through the rock, until they again reach the stratum of coal.

Coal, the chief mineral of Scotland, has been there worked for a succession of ages. Pope Pius II., in his description of Europe, written about 1450, mentions that he beheld with wonder black stones given as alms to the poor of Scotland. This mineral may, however, be traced to the twelfth century; and a very early account of the Scottish coal mines, explains with great precision, the manner of working the coal, not neglecting to mention the subterraneous walls of _whin_ which intersect the strata, particularly a remarkable one, visible from the river Tyne, where it forms a cataract, and passes by Prestonpans, to the shore of Fife. The Lothians and Fifeshire, particularly abound with this useful mineral, which also extends into Ayrshire; and near Irwin is found a curious variety, named ribbon-coal. A singular coal, in veins of mineral, has been found at Castle Leod, in the east of Ross-shire; and it is conjectured that the largest untouched field of coal in Europe, exists in a barren tract of country in Lanarkshire.

The process of mining coal is a combination of boring and digging. Shafts are sunk, levels are driven, and drains are carried off, by the help of picks or pickaxes, wedges and hammers, the rocks being also sometimes loosened by blasting with gunpowder. In searching for coal, a shaft is sunk through the uppermost soft stratum, and the rock is then bored, by striking it continually with an iron borer terminating in an edge of steel, which is in the mean time turned partly round; and, at proper intervals, a scoop is let down to draw up the loose fragments. In this manner a perforation is sometimes made for more than an hundred fathoms, the borer being lengthened by pieces screwed on; it is then partly supported by a counterpoise, and worked by machinery. Should it happen to break, the piece is raised by a rod furnished with a hollow cone, as an extinguisher, which is driven down on it. The borer is sometimes furnished with knives, which are made to act on any part at pleasure, and to scrape off a portion of the surrounding substance, which is collected in a proper receptacle.

Those who have the direction of deep and extensive coal mines, are obliged, with great art and care, to keep them ventilated with perpetual currents of fresh air, which afford the miners a constant supply of that vital fluid, and expel from the mines damps and other noxious exhalations, together with such other burnt and foul air, as has become deleterious and unfit for respiration. In the deserted mines, which are not thus ventilated with currents of fresh air, large quantities of these damps are frequently collected; and in such works they often remain for a long time without doing any mischief. But when, by some accident, they are set on fire, they then produce dreadful explosions, and, bursting out of the pits with great impetuosity, like the fiery eruptions from burning mountains, force along with them ponderous bodies to a great hight in the air.

Various instances have occurred in which the coal has been set on fire by the fulminating damp, and has continued burning for several months, until large streams of water were conducted into the mine, so as to inundate the parts where the conflagration existed. By such fires several collieries have been entirely destroyed, in the vicinity of Newcastle, and in other parts of England, as well as in Fifeshire, in Scotland. In some of these places the fire has continued to burn for ages. To prevent, therefore, as much as possible, the collieries from being filled with these pernicious damps, it has been found necessary carefully to search for the crevices in the coal whence they issue, and, at those places, to confine them within a narrow space, conducting them through large pipes into the open air, where, being set on fire, they consume in perpetual flame as they continually arise out of the earth.

Mr. Spelling, an engineer of the Whitehaven coal mines, having observed that the fulminating damp could only be kindled by flame, and that it was not liable to be set on fire by red-hot iron, nor by the sparks produced by the collision of flint and steel, invented a machine called a steel-mill, in which a wheel of that metal is turned round with a very rapid motion, and, by the application of flints, great plenty of sparks are emitted, which afford the miners such a light as enables them to carry on their work in close places, where the flame of a candle, or a lamp, would, as has already happened in various instances, occasion violent explosions. In that dreadful catastrophe, the explosion of the Felling colliery, the particulars of which will be hereafter detailed, it will be seen that mills of this description were employed, in searching for the remains of the victims of the sad disaster; but this event happened before the invention of Sir Humphrey Davy’s safety-lamp, a discovery which, while it affords a more certain light, holds out every security to the miner against accidents which, without such a resource, might still be superadded to those already recorded, as arising from the flame of a candle or lamp.

A greater number of mines have, however, been ruined by inundations than by fires; and here that noble invention, the fire-engine, displays its beneficial effects. It appears from nice calculations, that it would require about five hundred and fifty men, or a power equal to that of one hundred and ten horses, to work the pumps of one of the largest fire-engines, having a cylinder seventy inches in diameter, now in use, and thrice that number of men to keep an engine of that size constantly at work. It also appears that as much water may be raised by such an engine, as can be drawn, within the same space of time, by twenty-five hundred and twenty

men with rollers and buckets, after the manner long practiced in many mines; or as much as can be borne on the shoulders of twice that number of men, as is said to be done in several of the mines of Peru. So great is the power of the elastic steam of the boiling water in those engines, and of the outward atmosphere, which, by their alternate actions give force and motion to the beam, and through it to the pump rods which elevate the water through tubes, and discharge it from the mine!

Years since there were four fire-engines belonging to the Whitehaven colliery, which when all at work, discharged from it about twelve hundred and twenty-eight gallons of water every minute, at thirteen strokes; and at the same rate, one million, seven hundred and sixty-eight thousand, three hundred and twenty gallons, upward of seven thousand tuns, every twenty-four hours. By these engines nearly twice the above-mentioned quantity of water might be discharged from mines not more than sixty or seventy fathoms deep, which depth is rarely exceeded in the Newcastle collieries, or in any other English collieries, with the exception of the above.

Coal pits have sometimes taken fire by accident, and have continued to burn for a considerable length of time. About the year 1648, a coal mine at Benwell, a village near Newcastle-upon-Tyne, was accidentally kindled by a candle: at first the fire was so feeble, that a reward of half a crown, which was asked by a person who offered to extinguish it, was refused. It gradually increased, however, and had continued burning for thirty years, when the account was drawn up and published in the Philosophical Transactions: it was not finally extinguished until all the fuel was consumed. Examples of a similar kind have happened in Scotland and in Germany.

But of all the recorded accidents relative to coal mines, that of Felling colliery, near Sunderland, a concise narrative of which here follows, was the most disastrous.

Felling is a manor about a mile and a half east of Gateshead. It contains several strata of coal, the uppermost of which were extensively wrought in the beginning of the last century. The stratum called the high-main, was begun in 1779, and continued to be wrought till the nineteenth of January, 1811, when it was entirely excavated. The present colliery was in the seam called the low-main. It commenced in October, 1810, and was at full work in May, 1812. This mine was considered by the workmen as a model of perfection in the purity of its air, and orderly arrangements; its inclined plane was saving the daily expense of at least thirteen horses; the concern wore the features of the greatest possible prosperity, and no accident, except a trifling explosion of fire-damp, slightly burning two or three workmen, had occurred. Two _shifts_, or sets of men, were constantly employed, except on Sundays. Twenty-five acres of coal had been excavated. The first shift entered the mine at four o’clock, A. M., and were relieved at their working-posts by the next at eleven o’clock in the morning. The establishment employed under ground, consisted of about one hundred and twenty-eight persons, who, from the eleventh to the twenty-fifth of May, 1812, wrought six hundred and twenty-four scores of coal, equal to thirteen hundred Newcastle, or twenty-four hundred and fifty-five London chaldrons.

About half past eleven o’clock, on the morning of the twenty-fifth of May, 1812, the neighboring villages were alarmed by a tremendous explosion in this colliery. The subterraneous fire broke forth with two heavy discharges from the low-main, which were almost instantaneously followed by one from the high-main. A slight trembling, as from an earthquake, was felt for about half a mile around the workings; and the noise of the explosion, though dull, was heard to three or four miles’ distance, and much resembled an unsteady fire of infantry. Immense quantities of dust and small coal accompanied these blasts, and rose high into the air, in the form of an inverted cone. The heaviest part of the ejected matter, such as corves, pieces of wood, and small coal, fell near the pits; but the dust, borne away by a strong west wind, fell in a continued shower from the pit to the distance of a mile and a half. As soon as the explosion was heard, the wives and children of the workmen ran to the pit; the scene was distressing beyond the power of description.

Of one hundred and twenty-eight persons in the mine at the time of the explosion, only thirty-two were brought to daylight: twenty-nine survived the fatal combustion; the rest were destroyed. Nor from the time of the explosion till the eighth of July, could any person descend. But after many unsuccessful attempts to explore the burning mine, it was reclosed, to prevent the atmospheric air from entering it: this being done, no attempt was afterward made to explore it, till the morning of the last-mentioned day; from which time to the nineteenth of September, the heart-rending scene of mothers and widows examining the putrid bodies of their sons and husbands, for marks by which to identify them, was almost daily renewed; but very few of them were known by any personal mark; they were too much mangled and scorched to retain any of their features. Their clothes, tobacco-boxes, shoes, &c., were, therefore, the only indexes by which they could be recognized.

At the crane twenty-one bodies lay in ghastly confusion: some like mummies, scorched as dry as if they were baked. One wanted its head, another an arm. The scene was truly frightful. The power of fire was visible upon them all; but its effects were extremely variable: while some were almost torn to pieces, there were others who appeared as if they had sunk down overpowered with sleep. The ventilation concluded on Saturday the nineteenth of September, when the ninety-first body was dug from under a heap of stones. At six o'clock in the morning the pit was visited by candle-light, which had not been used in it for the space of one hundred and seventeen days; and at eleven o'clock in the morning the tube furnace was lighted. From this time the colliery has been regularly at work; but the ninety-second body has never yet been found. All these persons, except four, who were buried in single graves, were interred in Heworth chapel-yard, in a trench, side by side, two coffins deep, with a partition of brick and lime between every four coffins.

Having thus glanced at some of the coal mines of Great Britain, we now pass to some of those of the United States. In these coal is found in _four_ different forms: _first_, the _genuine_ anthracite, or _glance_ coal, as near Worcester, Mass., and Newport, R. I.; _second_, coal destitute of bitumen, commonly called anthracite, but which is more properly anasphaltic, which is found at Pottsville, Mauch Chunk, Lackawanna, Wilkesbarre, &c.; _third_, bituminous coal, usually found in the slate rock, as at Tioga, Lycoming, etc.; and _fourth_, the lignite coal, found along the south shore of the bay of South Amboy, New Jersey. From the state of Alabama to Pictou, Nova Scotia, the coal beds can be followed in a north-east direction, for fifteen hundred miles; and from Richmond, in Virginia, to Rock River, in Illinois, they are continually crossed at right angles, for about eight hundred miles. At Richmond, the coal is bituminous; on the Alleghany belt, it is anthracite. Geologists think that the anthracite was lifted out of its horizontal position when the great Alleghany belt was upheaved, and that its non-bituminous quality is owing to the influence of the intense heat that accompanied its upheaval.

Taylor, in his book on coal, estimates the area of bituminous coal in the United States, east of the Mississippi river, at one hundred and twenty-four thousand, seven hundred and thirty-five square miles, and west of the Mississippi, at eight thousand, three hundred and ninety-seven square miles; British North America, eighteen thousand square miles bituminous. More than one-third of the area of Pennsylvania, is more or less marked by coal formations; one-third of Kentucky, Ohio and Virginia, one-fifth of Indiana, and three-fourths of Illinois, are occupied by carboniferous strata. Western Pennsylvania abounds in bituminous coal, and it is found also in several counties of New York. By the census of 1839-40, we find that the quantity of bituminous coal produced that year in the United States, was twenty-seven million, six hundred and three thousand, one hundred and ninety-one bushels, employing about four thousand men, and a capital of some two million dollars; and that about four million dollars of capital were invested in raising anthracite coal, of which some nine hundred thousand tuns (of about twenty-eight bushels each) were produced by the labors of about three thousand men. Most of this was from Pennsylvania.

In 1819, the anthracite coal trade had no existence; in 1820, this kind of coal was first used as fuel, and just three hundred and sixty-five tuns were sent to market; in 1845, the amount was two million tuns; in 1850, about three million, five hundred thousand tuns, and the present year (1854) the amount will probably be between six and seven million tuns. The demand and supply so steadily and rapidly increase that it is impossible to estimate the vast extent the business of coal mining is yet to attain.

Glancing for a moment at other countries, we find that Belgium, in 1845, had two hundred and twelve mines, employing thirty-eight thousand miners and five hundred steam-engines, and producing five million tuns; France, four hundred and forty-nine mines, employing thirty thousand miners, and producing five million tuns; Prussia, in 1840, seven hundred and fifty-two mines, employing twenty-four thousand miners, and raising three million, five hundred thousand tuns; and that Great Britain, in 1846, produced thirty-five million tuns, valued at forty-five million dollars at the mines. Austria and Spain, also, have excellent mines, though less productive. And as a late and interesting discovery, it may be added, that the recent Arctic expedition sent out from England, found coal in those northern regions, on the island of Disco, outcropping near the shore. They also, in another locality not far off, discovered some curious specimens of petrified trees, and near them extensive quarries of anthracite coal, of good quality. There appeared to be no limit to the quantity that might be thrown into a boat with ease, and in the space of three hours they conveyed not less than twelve tuns to the steamer, three-quarters of a mile distant. It proved, on trial, to be of good quality, the combustion was perfect, and the coal as economical as the Welsh.

We will conclude the subject of coal mines, with the statement of a recent tourist, as to some of the wonders of the Cornish mines in England, as he saw them in 1854. He says: "Some of the mines are truly grand undertakings. The 'consolidated mines,' the largest of the Cornish group, employ upward of three thousand persons. One of the engines pumps water from a direct depth of sixteen hundred feet, the weight of the pumping apparatus alone being upward of five hundred tuns; the pumping-rod is one thousand, seven hundred and forty feet long, and it raises about two million gallons of water in a week, from a depth equal to five times the

hight of St. Paul's. These are, indeed, wonders to marvel at! The consolidated and united mines, both belonging to one company, are stated to have used the following vast quantities of materials in a year: coals, fifteen thousand, two hundred and seventy tuns; candles, one hundred and thirty-two thousand, one hundred and forty-four pounds; gunpowder, eighty-two thousand pounds; leather, for straps, &c., thirteen thousand, four hundred and ninety-three pounds; pick and shovel handles, sixteen thousand, six hundred and ninety-eight dozens. Sir Charles Lemon has estimated, that in the whole of the Cornish mines, thirteen thousand pounds' worth of gunpowder is used annually; that the timber employed in the underground works, equals the growth of one hundred and forty square miles of Norwegian forest; and that thirty-seven million tuns of water are raised annually from the mines."

SALT MINES.

Hence with diffusive salt old Ocean steeps, His emerald shallows, and his sapphire deeps. Oft in wide lakes, around their warmer brim, In hollow pyramids the crystals swim; Or, fused by earth-born fires, in cubic blocks Shoot their wide forms, and harden into rocks.—DARWIN.

Culinary salt, or, as it is termed in chemistry, muriate of soda, exists abundantly in a native state, both in a solid form, and dissolved in water. It occurs, in solution, not only throughout the wide range of the ocean, but in various springs, rivers and lakes; and is known, in its solid form, as a peculiar mineral, under the names of _rock-salt_, _fossil salt_, and _salt-gem_. Its beds are mostly beneath the surface of the ground, but sometimes rise into hills of considerable elevation. At Cordova, in Spain, a hill, between four and five hundred feet in hight, is nearly composed of this mineral. But the most celebrated salt mines are those of Wielicza, in Gallicia, commonly called the salt mines of Cracow, those of Tyrol, of Castile, (in Spain,) and of Cheshire, in England. In the province of Lahore, in Hindoostan, is a hill of rock-salt, of equal magnitude with that near Cordova. The mines of Iletski, in Russia, yield vast quantities of this substance. It is so plentiful in the desert of Caramania, and the air so dry, that it is there used as a material for building. It forms the surface of a large part of the northern desert of Lybia; and is found in great abundance in the mountains of Peru. It has a pure saline taste, without any mixture of bitterness; and crystallizes in cubes when obtained by slow evaporation from its solution. In Germany the mines of this kind are numerous: one of the largest is that of Hallein, near Saltzburg, in which the salt is hewn out from subterraneous caverns of a considerable range, and exhibits almost every diversity of color, as yellow, red, blue and white; in consequence of which it is dissolved in water, to be liberated from its impurities, and afterward recrystallized. The salt mines of Cracow, and those of Cheshire, merit a particular description.

SALT MINES OF CRACOW.

Thus, cavern'd round, in Cracow's mighty mines, With crystal walls a gorgeous city shines; Scoop'd in the briny rock long streets extend Their hoary course, and glittering domes ascend: Down their bright steeps, emerging into day, Impetuous fountains burst their headlong way, O'er milk-white vales in ivory channels spread, And wondering seek their subterraneous bed. Form'd in pellucid salt, with chisel nice, The pale lamp glittering through the sculptur'd ice, With wild reverted eyes fair Lotta stands, And spreads to heaven, in vain, her glassy hands; Cold dews condense upon her pearly breast, And the big tear rolls lucid down her vest. Far gleaming o'er the town, transparent fanes Rear their white towers, and wave their golden vanes: Long lines of lusters pour their trembling rays, And the bright vault resounds with mingled blaze.—DARWIN.

These celebrated excavations are about five miles distant from the city of Cracow, in a small town named Wielicza, which is entirely undermined, the cavities reaching to a considerable extent beyond its limits. The length of the great mine, a view of which is seen on the next page, from east to west, is six thousand feet; its breadth, from north to south, two thousand; and its greatest depth eight hundred; but the veins of salt are not limited to this extent, the depth and length of them, from east to west, being yet unknown, and their breadth only, hitherto determined. There are at present ten shafts; and not a single spring has been discovered throughout the extent of the mine.

In descending to the bottom, the visitor is surprised to find a kind of subterraneous commonwealth, consisting of many families, who have their peculiar laws and polity. Here are likewise public roads and carriages, horses being employed to draw the salt to the mouths of the mine, where it is taken up by engines. These horses, when once arrived at their destination, never more see the light of the sun; and many of the people seem buried alive in this strange abyss, having been born there, and never stirring out; while others are not denied frequent opportunities of breathing the fresh air in the fields, and enjoying the surrounding prospects. The subterraneous passages, or galleries, are very spacious, and in many of them chapels are hewn out of the rock-salt. In these passages crucifixes are set up, together with the images of saints, before which a light is kept constantly burning. The places where the salt is hewn out, and the empty cavities whence it has been removed, are called chambers, in several of which, where the water

has stagnated, the bottoms and sides are covered with very thick incrustations of thousands of salt crystals, lying one on the other, and many of them weighing half a pound and upward. When candles are placed before them, the numerous rays of light reflected by these crystals emit a surprising luster.

[Illustration: GREAT SALT MINE OF CRACOW.]

In several parts of the mine, huge columns of salt are left standing, to support the rock; and these are very fancifully ornamented. But the most curious object in the inhabited part, or subterraneous town, is a statue which is considered by the immured inhabitants as the actual transmutation of Lot's wife into a pillar of salt; and in proportion as this statue appears either dry or moist, the state of the weather above ground is inferred. The windings in this mine are so numerous and intricate, that the workmen have frequently lost their way; and several, whose lights have been extinguished, have thus perished. The number of miners to whom it gives employment, is computed at between four and five hundred; but the whole amount of the men employed in it is about seven hundred.

The salt lies near the surface, in large, shapeless masses, from which blocks of sixty, eighty, or a hundred feet square, may be hewn; but at a considerable depth it is found in smaller lumps. About six hundred thousand quintals of salt are dug annually out of the mines of Cracow. The worst and cheapest is called green salt, from its greenish color, occasioned by a heterogenous mixture of a grayish mineral, or clay, and entirely consists of salt crystals of different dimensions. A finer sort is dug out in large blocks; and the third kind is the _sal gemmæ_, or crystal salt, which is found in small pieces interspersed in the rock, and, when detached from it, breaks into cubes of rectangular prisms. This is usually sold unprepared. The color of the salt stone is a dark gray mixed with yellow.

SALT MINES AND SPRINGS OF CHESHIRE, ENGLAND.

The Cheshire rock-salt, with very few exceptions, has hitherto been ascertained to exist only in the valleys bordering on the river Weaver and its tributary streams; in some places manifesting its presence by springs impregnated with salt, and in others being known by mines actually carried down into the substance of the salt strata. Between the source of the Weaver and Nantwich, many brine springs make their appearance; and occur again at several places, in proceeding down the stream. At Moulton, a mine has been sunk into the body of rock-salt, and a similar mine is wrought near Middlewich. At Northwich, brine springs are very abundant; and there also many mines have been sunk for the purpose of working out the fossil salt. In that vicinity a body of rock-salt has been met with in searching for coal.

The brines in this district are formed by the penetration of spring or rain waters to the upper surface of the rock-salt, in passing over which they acquire such a degree of strength, that one hundred parts have yielded twenty-seven of pure salt, thus nearly approaching to the perfect saturation of brine. Their strength is therefore much greater than that of the salt springs met with in Hungary, Germany and France. The brine having been pumped out of the pits, is first conveyed into large reservoirs, and afterward drawn off as it is needed, into pans made of wrought iron. Here heat is applied in a degree determined by the nature of the salt to be manufactured, and various additions are made to the brine, with a view either to assist the crystallization of the salt, or to promote the separation of the earthy particles, which exist in a very small proportion. The importance of the manufacture of Cheshire salt will be sufficiently obvious from the statement, that, besides the salt made for home consumption, the annual amount of which has exceeded sixteen thousand tuns, the average of the quantity sent yearly to Liverpool for exportation, has not been less than one hundred and forty thousand tuns.

The mine of rock-salt first worked was discovered by accident at Marbury, near Northwich about a century and a half ago; and this bed had been wrought for more than a century, when, in the same neighborhood, a second and inferior stratum was fallen in with, separated from the former by a bed of indurated clay. This lower stratum was ascertained to possess a very great degree of purity, and freedom from earthy admixture; on which account, and from the local advantages of Northwich for exportation, the fossil salt is worked in the vicinity of that place only. It occurs in two great strata or beds, lying nearly horizontally, and separated, the superincumbent from the subjacent stratum, by several layers of indurated clay, or argillaceous stone. These intervening beds possess, in conjunction, a very uniform thickness of from thirty to thirty-five feet, and are irregularly penetrated by veins of fossil salt. There is every reason to believe that the beds of rock-salt at Northwich, are perfectly distinct from any others in the salt district, and form what are termed by mineralogists _incumbent bodies_ or _masses of mineral_.

These enormous masses stretch a mile and a half in a longitudinal direction from north-east to south-west; but their transverse extent, as measured by a line at right angles from the former, does not exceed forty-two hundred feet, somewhat more than

three-quarters of a mile. Without this area, the brine which is met with, is of a very weak and inferior quality, and at a short distance disappears altogether. The thickness of the upper bed varies from sixty to ninety feet; and a general estimate made from its level, shows that its upper surface, which is ninety feet beneath that of the earth, is at least thirty-six feet beneath the low-water mark of the sea at Liverpool; a fact not unimportant in determining the nature of the formation of this mineral. The thickness of the lower bed has not hitherto been ascertained; but the workings are usually begun at the depth of from sixty to seventy-five feet, and are carried down for the space of fifteen or eighteen feet, through what forms the purest portion of the bed. In one of the mines a shaft has been sunk to a level of forty-two feet still lower, without passing through the body of rock-salt. There is thus an ascertained thickness of this bed of about a hundred and twenty feet, and without any direct evidence that it may not extend to a considerably greater depth.

Although two distinct beds, only, of fossil salt have been met with at Northwich, it has been ascertained that the same limitations do not exist throughout the whole of the salt district. At Lawton, near the source of the river Wheelock, three distinct beds have been found, separated by strata of indurated clay: one at the depth of one hundred and twenty-six feet, four feet in thickness; a second, thirty feet lower, twelve feet in thickness; and a third, forty-five feet further down, which was sunk into seventy-two feet, without passing through its substance. The intervening clay, the structure of which is very peculiar, is called the shaggy metal, and the fresh water which passes through its pores has the expressive appellation of Roaring Meg. This epithet will not appear too strong, when it is mentioned that in a mine in which the section of strata was taken, and where the “shaggy metal” was found at the depth of about eighty feet, the quantity of water ascertained to issue from its pores in one minute, was not less than three hundred and sixty gallons; a circumstance which greatly enhances the difficulty of passing a shaft down to the body of rock-salt.

In many of these beds of argillaceous stone, a portion of salt, sufficiently strong to affect the taste, is found to exist; and this saltness increases, as might be expected, in proportion as the body of rock-salt is approached. In the strata or layers immediately above the rock, which in all the mines are perfectly uniform in their appearance and structure, this is particularly remarkable, notwithstanding there are not, in these strata, any veins of rock-salt connected with the great mass below. On the contrary, the line between the clay and rock-salt is drawn with great distinctness in every instance, without presenting any of those inequalities which would arise from a mutual penetration of the strata. Not any marine exuviæ, or organic remains, are found in the strata above the rock-salt; and the almost universal occurrence of gypsum, in connection with beds of fossil salt, is a fact still more deserving of observation, because it appears, not only in these mines, but also in the salt mines of Hungary, Poland and Transylvania; on which account Werner, in his geognostic system, assigns to the rock-salt and fletz gypsum a conjunct situation.

The fossil salt extracted from the Northwich mines is of different degrees of purity, and more or less blended with earthy and metallic substances. The purer portion of the lower bed yields a rock-salt, which, being principally exported to the Baltic, obtains the name of Prussian rock. The extent of the cavity formed by the workings, varies in different mines, the average depth being about sixteen feet. In some of the pits, where pillars from eighteen to twenty-four feet square form the supports of the mine, the appearance of the cavity is singularly striking, and the brilliancy of the effect is greatly increased when the mine is illuminated by candles fixed to the sides of the rock. The scene thus formed almost appears to realize the magic palaces of eastern poets. Some of the pits are worked in aisles or streets, but the choice here is wholly arbitrary. Among the methods employed in working out the rock-salt, the operation of blasting is applied to the separation of large masses from the body of the rock, and these are afterward broken down by the mechanical implements in common use. The present number of mines is eleven or twelve, from which there are raised, on an annual average, fifty or sixty thousand tuns of rock-salt. The greater part of this quantity is exported to Ireland and the Baltic, the remainder being employed in the Cheshire district, in the manufacture of white salt, by solution and subsequent evaporation.

The general situation occupied by the rock-salt in Cheshire is very similar to that of the Transylvanian and Polish mines, the beds of this mineral being disposed in small plains, bounded by hills of inconsiderable hight, forming a kind of basin or hollow, from which there is usually only a narrow egress for the waters. The situation of the Austrian salt mines near Saltzburg is, however, very different. The mineral there appears to be disposed in beds of great thickness, which occur near the summits of limestone hills, at a great elevation above the adjoining country. This is a singular fact; and if the hypothesis be allowed that rock-salt is formed from the waters of the sea, it is necessary to suppose the occurrence on this spot of the most vast and surprising changes!

Though there are no salt _mines_ in the United States, there are salt _springs_ in several places. By far the most important and valuable of these, are in the neighborhood of Syracuse, in the state of New York. The land containing these springs, is owned by the state, and is leased free of rent, to be used only for the manufacture of salt. The wells are dug, and the water pumped up at the expense of the state, and the manufacturer pays a duty of one cent on each bushel he makes. Some of the wells are sunk to the

depth of four hundred feet. Fine salt is prepared by boiling; and coarse by solar evaporation. In 1850, the number of salt manufactories in this vicinity was one hundred and ninety-two; and the quantity of salt produced in 1853, amounted to more than five million bushels. The salt of this region has been thoroughly tested, and found to be fully equal to any of foreign manufacture.

PHENOMENA OF THE OCEAN.

“They that go down to the sea in ships, that do business in great waters; these see the works of the Lord, and his wonders in the deep.”—PSALMS.

“With wonder mark the moving wilderness of waves, From pole to pole through boundless space diffused, Magnificently dreadful! where, at large, Leviathan, with each inferior name Of sea-born kinds, ten thousand thousand tribes, Find endless range for pasture and for sport. Adoring own The Hand Almighty, who in channeled bed Immeasurable sunk, and poured abroad, Fenced with eternal mounds, the fluid sphere; With every wind to waft large commerce on. Join pole to pole, consociate severed worlds, And link in bonds of intercourse and love Earth’s universal family.”—MALLET.

That huge mass of waters impregnated with salt, which encompasses all parts of the globe, and by the means of which, in the present improved state of navigation, an easy intercourse subsists between the most distant nations, is denominated the ocean, and has three grand divisions assigned to it. First, that vast expanse of water which lies to the westward of the northern and southern continents of America, and by which those continents are divided from Asia. On account of the uniform and temperate gales which sweep its surface within the tropics, it is named the Pacific ocean; and has again been distinguished into the northern and southern Pacific, (the equator being considered as the dividing line,) and the Southern ocean, or South sea, being consequently that part of the general assemblage of waters which is contained between the fortieth degree of south latitude and the south pole. Its general width is estimated at about ten thousand miles. Secondly, the Atlantic ocean, which divides Europe and Africa from the two American continents, and has a general width of about three thousand miles; while the waters which occupy the polar regions are named the Northern sea. And, lastly, the Indian ocean, which extends from the eastern shores of Africa along the southern coasts of Asia, and has the same general width with the preceding one.

Among the chief of those less expansive sheets of water, properly called seas, may be mentioned the Baltic, the Mediterranean sea, and the Black and Red seas. The Caspian sea, being entirely encompassed by land, might, with more propriety, have been styled a lake; but as its water possesses the quality of saltness, it is ranked among the seas. It is, notwithstanding, certain that Lake Superior has a still greater circumference, extending around its shores at least fourteen hundred miles, while the extent of the Caspian does not exceed twelve hundred.

Of the origin of this division into different seas, and seas of different depths, little is known; but it is highly probable that many of the larger excavations and partitions now met with, have existed, without much change as to their extent, from the creation. Others have undoubtedly been the result of that conflict which is perpetually taking place between the elements of land and water, and which has, for the greater part, given rise to islands, isthmuses and peninsulas; while subterraneous volcanoes, and the truly surprising and indefatigable exertions of coral, madrepores, tubipores, and other restless and multitudinous zoöphytes, have laid, and are daily laying, the foundation of new islands and continents in the middle of the widest and deepest seas.

The quantity of water in the ocean, not only remains constantly the same, but, notwithstanding its most violent and incessant motion, continues stable within certain limits. This, however, can not be inferred from observation; for, although in the almost infinite variety of disturbances to which the ocean is liable, from the action of irregular causes, it may appear to return to its former state of equilibrium, still it may be apprehended that some extraordinary cause may communicate to it a shock, which, though inconsiderable at first, may augment continually, and elevate it above the highest mountains. It is, therefore, interesting to investigate the conditions which are necessary for the absolute stability of the ocean. This has been effected by the celebrated Laplace, who has demonstrated that the equilibrium of the ocean _must_ be stable, if the density be _less_ than the mean density of the earth, which is known to be the case. He has likewise determined, by means of his refined analysis, that this stability would cease to exist, if the mean density of the sea _were to exceed_ that of the earth; so that the stability of the equilibrium of the ocean, and the excess of the density of the terrestrial globe above that of the waters which cover it, are reciprocally connected with each

other, and indicate infinite wisdom and contrivance in such an adjustment.

SALTNESS OF THE SEA.

Of the various phenomena of the sea, that of its _saltness_ is one of the most obvious. No questions concerning the natural history of our globe have been discussed with more attention, or decided with less satisfaction, than that concerning its primary cause, which had perplexed the philosophers before the time of Aristotle, and surpassed even the great genius of that profound inquirer into natural causes. Kircher, after having consulted not less than thirty-three authors on this subject, could not help remarking, that the fluctuations of the ocean itself were scarcely more various than the opinions concerning the origin of its saline impregnation.

This question does not seem capable of admitting an illustration from experiment; at least, not from any experiments hitherto made for that purpose: it is, therefore, not surprising, that it remains nearly as problematical in the present age, as it has been in any of the preceding. Had observations been made three or four centuries ago, to ascertain the saltness of the sea, then, at any particular time and place, we might now, by making similar observations at the same place, in the same season, have been able to know, whether the saltness, at that particular place, was increasing or decreasing, or an invariable quantity. This kind and degree of knowledge would have served as a clue to direct us to a full investigation of this matter in general. It is to be regretted, however, that observations of this nature have not, in former days, been made with any degree of precision.

One of the principal opinions maintained on this subject by modern philosophers, and more particularly supported by Halley, is, that since river-water, in almost every part of the globe, is impregnated in a greater or less degree by sea-salt, the sea must have gradually acquired its present quantity of salt from the long continued influx of rivers. The water which is carried into the sea by these rivers, is again separated from it by evaporation, and being dispersed over the atmosphere by winds, soon descends in rain or vapor upon the surface of the earth, whence it hastens to pour into the bosom of the ocean the fresh tribute of salt it has collected in its inland progress. Thus the salt conveyed into the sea not being a volatile substance, nor performing an incessant circulation, must be a perpetually increasing quantity; and sufficient time, it is contended, has elapsed since the creation, for the sea to acquire, from this source, its present quantity of salt.

This opinion has been successfully combated; and it is denied that freshwater rivers could, in the course of thousands or even millions of years, have produced saltness in the sea. If this were the case, every sea, or great body of water, which receives rivers, must have been salt, and have possessed a degree of saltness in proportion to the quantity of water which these rivers discharge. But so far is this from being true, that the Palus Mæotis, and our great American lakes, do not contain salt water, but fresh. It may indeed be objected, that the quantity of salt which rivers carry along with them, and deposit in the sea, must depend on the nature of the soil through which they flow, which may in some places not contain any salt; and that this is the reason why the great lakes in America and the Palus Mæotis are fresh. But to this opinion, which is merely hypothetical, there are insurmountable objections. It is a curious fact, that the saltness of the sea is greatest under the equator, and diminishes gradually toward the poles; but it can not therefore be assumed that the earth contains more salt in the tropical regions than in the temperate zones, and more in these again than in the frigid zones. On the other hand, if it be allowed that the sea receives its saltness from the rivers, it must be equally salt, or nearly so, in every part of the earth; since, according to a simple and well-known principle in chemistry, _when any substance is dissolved in water with the assistance of agitation, at whatever part of the water it is introduced, it will be equally diffused through the whole liquid_. Now, though it were true that a greater quantity of salt should have been introduced into the sea under the equator, than toward the poles, from the constant agitation occasioned by the wind and tide, the salt must have soon pervaded the whole mass of water. Neither is this greater proportion of saltness owing to a superior degree of heat, since it is an established principle in chemistry, that cold water and hot water dissolve nearly the same proportion of salt.

The saltness of the sea has also been ascribed to the solution of subterraneous mines of salt, that are supposed to abound in the bottom of the sea, and along its shores. But this hypothesis can not be supported. If the sea were constantly dissolving salt, it would soon become saturated; for it can not be said that it is deprived of any portion of its salt by evaporation, since rain-water is fresh. If the sea were to become saturated, neither fishes nor vegetables could live in it. It may hence be inferred that the saltness of the sea can not be accounted for by secondary causes, and _that it has been salt since the beginning of time_. It is indeed impossible to suppose that the waters of the sea were at any time fresh since the formation of fishes and sea-plants; neither will they live in water which is fresh. It may hence be concluded that the saltness of the sea has, with some few exceptions, perhaps arising from mines of rock-salt dispersed near its shores, been nearly the same in all ages. This hypothesis, which is the simplest, and is involved in the fewest difficulties, best explains the various phenomena dependent on the saltness of the sea.

Although this saline property may be one of the causes by which the waters of the sea are preserved from putridity, still it can not be considered as the principal cause. The ocean has, like rivers, its currents, by which its contents are circulated round the globe; and these may be said to be the great agents which keep it sweet and wholesome. A very enlightened navigator, Sir John Hawkins, speaks of a calm, in which the sea, having continued for some time without motion, assumed a very formidable aspect. “Were it not,” he observes, “for the moving of the sea by the force of winds, tides and currents, it would corrupt all the world. The experiment of this I saw in the year 1590, lying with a fleet about the islands of the Azores, almost six months, the greater part of which time we were becalmed. Upon which, all the sea became so replenished with various sorts of gellies, and forms of serpents, adders and snakes, as seemed wonderful; some green, some black, some yellow, some white, some of divers colors, and many of them had life; and some there were a yard and a half, and two yards long; which, had I not seen, I could hardly have believed. And hereof are witnesses all the companies of the ships which were then present; so that hardly a man could draw a bucket of water clear of some corruption. In which voyage, toward the end thereof, many of every ship fell sick, and began to die apace. But the speedy passage into our country, was a remedy to the diseased, and a preservative to those who were not touched.”

CONGELATION OF SEA-WATER.

Although the assertion that salt water never freezes, has been contradicted by repeated experience, it is still certain that it requires a much greater degree of cold to produce its congelation, than fresh water. It is, therefore, one of the greatest blessings which we derive from this element, that when we find all the stores of nature locked up to us on the land, the sea is, with few exceptions, ever open to our necessities. It is well known that at particular seasons, the mouth of the river St. Lawrence, the entrance into the Baltic sea, &c., are so much frozen over as to be impassable by ships; while the vast mountains and fields of ice in the polar regions, have for ages past been insurmountable obstructions to the daring researches of modern navigators. These exceptions, however, will appear of comparatively trifling importance to navigation, when the number of ports which are, in almost every region, open at all seasons of the year, are considered; and this facility of intercourse would certainly not have been afforded, if sea-water had admitted of as easy a congelation as that of water not impregnated with salt.

On the origin of ice in the frozen seas, different opinions have been entertained. The authority of Capt. Cook and Lord Mulgrave, has been cited by Bishop Watson, to show that good fresh water may be procured from ice found in those seas; but he observes that, notwithstanding the testimonies of these very able navigators, it may still be doubted whether the ice from which the water was obtained, had been formed in the sea, and, consequently, whether sea-water itself would, when frozen, yield fresh water. He thinks it probable that the ice had either been formed at the mouths of large fresh-water rivers, and had thence, by tides or torrents been drifted into the sea, or that it had been broken by its own weight, from the immense cliffs of ice and frozen snow which, in countries where there are few rivers, are found in high latitudes to project a great way into the sea. An early navigator, Fotherbye, in the relation of his voyage toward the south pole, in 1614, considers snow to be the original cause of the ice found at sea, he himself having observed it to lie an inch thick on the surface; and Captain Cook, from his own observation in the South sea, was disposed to think that the vast floats of ice he met with in the spring, were formed from the congelation of snow. It is certain that the snow which falls upon the surface of the sea, being in a solid state, and, bulk for bulk, lighter than sea-water, will not readily combine with it, but may, by a due degree of cold in the atmosphere, be speedily converted into a layer of ice. The upper layer of this first surface of ice being elevated above the surface of the sea, will receive all the fresh water which falls from the atmosphere in the form of snow, sleet, rain or dew, by the successive congelation of which, the largest fields of ice may at length be formed.

It is a matter of little consequence to a navigator, whence the ice which supplies him with fresh water is produced. Leaving, therefore, these hypotheses relative to the formation of ice in frozen seas, it should be observed that the question, whether congealed sea-water will, when thawed, yield fresh water, has been satisfactorily decided by experiments made with every suitable attention. A quantity of sea-water having been taken up off the English coast, was exposed to a freezing atmosphere, and afforded an ice perfectly free from any taste of salt; and it has likewise been found, that not only sea-water, but water containing double the proportion of salt commonly found in our sea-water, and more than is contained in the sea-water of any climate, may be frozen by the cold prevailing in our atmosphere.

[Illustration: ICEBERGS, OR ICE-ISLANDS.]

ICE-ISLANDS.

Ice-islands, or icebergs, as they are commonly called, is the name given by seamen to the huge, solid masses of ice which abound in the sea near or within the polar circles, and which often float down nearer to the equator, till they are gradually dissolved by the

increasing warmth of the air and water. The cut gives a view of them as seen by Dr. Scoresby, who counted five hundred of them between latitude sixty-nine degrees and seventy degrees north, which were from one hundred to two hundred feet high, and from a few yards to a mile in circumference. Many of these fluctuating islands are met with on the coasts of Spitzbergen, to the great danger of the vessels employed in the Greenland fishery. In the midst of these tremendous masses, navigators have been arrested and frozen to death. In this manner the brave Sir Hugh Willoughby perished, with all his crew, in 1553; and in the year 1773, Lord Mulgrave, after every effort which the most accomplished seaman could make, to reach the termination of his voyage, was caught in the ice, and nearly experienced the same unhappy fate. The scene he describes, divested of the horrors attendant on the eventful expectation of change, was most beautiful and picturesque. Two large ships becalmed in a vast basin, surrounded on all sides by ice-islands of various forms; the weather clear; the sun gilding the circumambient ice, which was smooth, low, even, and covered with snow, except where pools of water, on a portion of the surface, shot forth new icy crystals, and on the smooth surface of the comparatively small space of sea in which they were hemmed. Such is the picture drawn by our navigator, amid the perils by which lie was surrounded.

After fruitless attempts to force their way through the fields of ice, the limits of these became at length so contracted, that the ships were immovably fixed. The smooth extent of surface was soon lost; the pressure of the pieces of ice, by the violence of the swell, caused them to pack; and fragment rose upon fragment, until they were in many places higher than the main-yard. The movements of the ships were tremendous and involuntary, in conjunction with the surrounding ice, actuated by the currents. The water having shoaled to fourteen fathoms, great apprehensions were entertained, as the grounding of the ice, or of the ships, would have been equally fatal: the force of the ice might have crushed them to atoms, or have lifted them out of the water, and have overset them; or, again, have left them suspended on the summits of the pieces of ice, at a tremendous hight, exposed to the fury of the winds, or to the risk of being dashed to pieces by the failure of their frozen dock. An attempt was made to cut a passage through the ice; but after a perseverance truly worthy of Britons, it proved ineffectual. The commander, who was at all times master of himself, directed the boats to be made ready to be hauled over the ice, till they should reach navigable water, proposing in them to make the voyage to England; but after they had thus been drawn over the ice, for three progressive days, a wind having sprung up, the ice separated sufficiently to yield to the pressure of the ships in full sail. After having labored against the resisting fields of ice, they at length reached the harbor of Smeerinberg, at the west end of Spitzbergen.

The vast islands of floating ice which abound in the high southern latitudes, are a proof that they are visited by a much severer degree of cold than equal latitudes toward the north pole. Captain Cook, in his second voyage, fell in with one of these islands in latitude fifty degrees, forty minutes, south. It was about fifty feet high, and half a mile in circuit, being flat on the top, while its sides, against which the sea broke exceedingly high, rose in a perpendicular direction. In the afternoon of the same day, the tenth of December, 1773, he fell in with another large cubical mass of ice, about two thousand feet in length, four hundred feet in breadth, and in hight two hundred feet. Mr. Foster, the naturalist of the voyage, remarks that, according to the experiments of Boyle and Marian, the volume of ice is to that of sea-water as ten to nine: consequently, by the known rules of hydrostatics, the volume of ice which rises above the surface of the water, is to that which sinks below it as one to nine. Supposing, therefore, this mass of ice to have been of a regular figure, its depth under water must have been eighteen hundred feet, and its whole hight, twenty hundred feet: estimating its length, as above, at twenty hundred feet, and its breadth at four hundred feet, the entire mass must have contained sixteen hundred millions of cubic feet of ice.

Two days after, several other ice-islands were seen, some of them nearly two miles in circuit, and six hundred feet high; and yet such was the force of the waves, that the sea broke quite over them. They exhibited for a few moments a view very pleasing to the eye; but a sense of danger soon filled the mind with horror; for had the ship struck against the weather-side of one of these islands, when the sea ran high, she must in an instant have been dashed to pieces. The route to the southward was afterward impeded by an immense field of low ice, the termination of which could not be seen, either to the east, west or south. In different parts of this field were islands, or hills of ice, like those which had before been found floating in the sea.

At length these ice-islands became as familiar to those on board as the clouds and the sea. Whenever a strong reflection of white was seen on the skirts of the sky, near the horizon, then ice was sure to be encountered; notwithstanding which, that substance itself was not entirely white, but often tinged, especially near the surface of the sea, with a most beautiful sapphirine, or rather berylline blue, evidently reflected from the water. This blue color sometimes appeared twenty or thirty feet above the surface, and was probably produced by particles of sea-water which had been dashed against the mass in tempestuous weather, and had penetrated into its interstices. In the evening, the sun setting just behind one of these masses, tinged its edges with gold, and reflected on the entire mass a beautiful suffusion of purple. In the larger masses, were frequently observed shades or casts of

white, lying above each other in strata, sometimes of six inches, and at other times of a foot in hight. This appearance seemed to confirm the opinion entertained relative to the increase and accumulation of such huge masses of ice, by heavy falls of snow at different intervals; for snow being of various kinds, small-grained, large-grained, in light feathery locks, &c., the various degrees of its compactness may account for the different colors of the strata.

In his third attempt to proceed southward, in January, 1774, Capt. Cook was led, by the mildest sunshine which was, perhaps, ever experienced in the frigid zone, to entertain hopes of penetrating as far toward the south pole as other navigators have done toward the north pole; but on the twenty-sixth of that month, at four in the morning, his officers discovered a solid ice-field of immense extent before them, bearing from east to west. A bed of fragments floated around this field, which was raised several feet above the surface of the water. While in this situation, the southern part of the horizon was illuminated by the rays of light reflected from the ice, to a considerable hight. Ninety-seven ice-islands were distinctly seen within the field, besides those on the outside; many of them very large, and looking like a ridge of mountains, rising one above the other until they were lost in the clouds. The most elevated and most ragged of these ice-islands, were surmounted by peaks, and were from two to three hundred feet in hight, with perpendicular cliffs or sides astonishing to behold. The largest of them terminated in a peak not unlike the cupola of St. Paul's.

The outer, or northern edge of this immense field of ice, was composed of loose or broken ice, closely packed together, so that it was not possible to find any entrance. Such mountains of ice, Captain Cook was persuaded, were never seen in the Greenland seas, so that no comparison could be drawn; and it was the opinion of most of the persons on board, that this ice extended quite to the pole, from which they were then less than nineteen degrees; or, perhaps, that it was joined to some land to which it had been fixed from the earliest time. Our navigator was of opinion that it is to the south of this parallel that all the ice is formed which is found scattered up and down to the northward, and afterward broken off by gales of wind, or other causes, and brought forward by the currents which are always found to set in that direction in high latitudes. "Should there," he observes, "be land to the south behind this ice, it can afford no better retreat for birds, or any other animals, than the ice itself, with which it must be wholly covered. I, who was ambitious, not only to go further than any one had been before, but as far as it was possible for man to go, was not sorry at meeting with this interruption; as it in some measure relieved us, or at least shortened the dangers and hardships inseparable from the navigation of the southern polar regions."

The approximation of several fields of ice of different magnitudes, produces a very singular phenomenon. The smaller of these masses are forced out of the water, and thrown on the larger ones, until at length an aggregate is formed of a tremendous hight. These accumulated bodies of ice float in the sea like so many rugged mountains, and are continually increased in hight by the freezing of the spray of the sea, and the melting and then freezing of the snow which falls on them. While their growth is thus augmented, the smaller fields, of a less elevation, are the meadows of the seals, on which these animals at times frolic by hundreds.

The collision of great fields of ice, in high latitudes, is often attended by a noise, which, for a time, takes away the sense of hearing anything beside; and that of the smaller fields, with a grinding of unspeakable horror. The water which dashes against the mountainous ice, freezes into an infinite variety of forms, and presents to the admiring view of the voyager ideal towns, streets, churches, steeples, and almost every form which imagination can picture to itself.

After such notices of the ice-islands from the earlier voyagers, it may be interesting to know how they have appeared to later beholders; and this may be seen in the following account from the journal of a seaman who was in the well known "Arctic Expedition," in 1850-51. Under the date of the thirtieth of June, 1850, he writes: "Moored to an iceberg; weather calm; sky cloudless, and 'beautifully blue;' surrounded by a vast number of stupendous bergs, glittering and glistening beneath the refulgent rays of a midday sun. A great portion of the crew had gone on shore to gather the eggs of the wild sea-birds that frequent the lonely ice-bound precipices of Baffin's bay, while those on board had retired to rest, wearied with the harassing toils of the preceding day. To me, walking the deck and alone, all nature seemed hushed in universal repose. Whilst thus contemplating the stillness of the monotonous scene around me, I observed in the offing a large iceberg, completely perforated, exhibiting in the distance an arch, or tunnel, apparently so uniform in its conformation, that I was induced to call two of the seamen to look at it, at the same time telling them, that I had never read or heard of any of our arctic voyagers passing through one of these arches, so frequently seen through large bergs, and that there would be a novelty in doing so; and if they chose to accompany me, I would get permission to take the small boat, and endeavor to accomplish the unprecedented feat.

"They readily agreed, and away we went. On nearing the arch, and ascertaining that there was a sufficiency of water for the boat to pass through, we rowed slowly and silently under, when there burst upon our view one of the most magnificent specimens of

nature's handiwork ever exhibited to mortal eyes; the sublimity and grandeur of which no language can describe, no imagination conceive. Fancy an immense arch of eighty feet span, fifty feet high, and upward of one hundred feet in breadth, as correct in its conformation as if it had been constructed by the most scientific artist, formed of solid ice, of a beautiful emerald green, its whole expanse of surface smoother than the most polished alabaster, and you may form some slight conception of the architectural beauties of this icy temple, the wonderful workmanship of time and the elements. When we had got about half-way through the mighty structure, on looking upward, I observed that the berg was rent the whole breadth of the arch, and in a perpendicular direction to its summit, showing two vertical sections of irregular surfaces, 'darkly, deeply, beautifully blue,' here and there illuminated by an arctic sun, which darted its golden rays between, presenting to the eye a picture of ethereal grandeur, which no poet could describe, no painter portray. I was so enraptured with the sight, that for a moment I fancied the 'blue vault of heaven' had opened, and that I actually gazed upon the celestial splendor of a world beyond this. But, alas! in an instant the scene changed, and I awoke as it were from a delightful dream, to experience all the horrors of a terrible reality. I observed the fracture rapidly close, then again slowly open. This stupendous mass of ice, millions of tuns in weight, was afloat, consequently in motion, and apparently about to lose its equilibrium, capsize, or burst into fragments.

"Our position was truly awful. My feelings at the moment may be conceived, but can not be described. I looked downward and around me; the sight was equally appalling; the very sea seemed agitated. I at last shut my eyes from a scene so terrible, the men at the oars, as if by instinct, 'gave way,' and our little craft swiftly glided from beneath the gigantic mass. We then rowed round the berg, keeping at a respectful distance from it, in order to judge of its magnitude. I supposed it to be about a mile in circumference, and its highest pinnacle two hundred and fifty feet. Thus ended an excursion, the bare recollection of which, at this moment, awakens in me a shudder; nevertheless, I would not have lost the opportunity of witnessing a scene so awfully sublime, so tragically grand, for thousands of pounds, but I would not again run such a risk for a world. We passed through the berg about two P. M., and at ten o'clock the same night, it burst, agitating the sea for miles around. I may also observe, that the two men who were with me in the boat, did not observe that the berg was rent until I told them, after we were out of danger, we having agreed, previously to entering the arch, not to speak a word to each other, lest echo itself should disturb the fragile mass."

As further describing the appearances of icebergs, we give the following narrative by Mr. Abbott, who himself was a witness of the splendid scenery he so graphically describes. He says: "The trip of the Baltic, in March, 1854, is likely to be somewhat memorable. We left Sandy Hook, on Sunday morning, the fifth, and had a propitious and rapid run, until Friday the tenth, about three o'clock. When in latitude forty-six degrees and longitude forty-eight degrees, our attention was arrested by some small pieces of broken ice, floating in every direction around us. The weather was thick and hazy, so that we could nowhere see the horizon. In the course of an hour or two, the fog partly disappeared, and we found ourselves nearly half-surrounded by an immense field of drift-ice, and large numbers of icebergs, extending from north-east by south to south-west.

"Our speed was immediately slackened, and the course of the ship changed to the northward and westward. It soon appeared that we were completely hemmed in on every side, by immense fields of floating drift, sometimes in loose and broken masses, sometimes in a compact and immovable jam, and everywhere studded with vast and towering icebergs, of almost every conceivable form and size.

"The fog gradually lifted, now in one direction, and now in another, just sufficient to discover to us, that we were fairly surrounded, and that, to whatever point of the compass we could turn the eye or the ship, interminable masses of drift-ice, of uplift, and icebergs, seemed to cover the sea. So sudden and unexpected was this discovery, that it seemed more like fairy work than reality. Surprise and astonishment, at the novel and wonderful scene around us, seemed at first to make us all unconscious of our own critical situation. Separating from it the idea of danger, it would be difficult to imagine a scene combining and blending more of the elements of beauty, grandeur and sublimity. Far as the eye could reach, it was no longer sea and sky, but ice, ice, ice, floating like an archipelago of a thousand isles, great and small, of highland and lowland, mountain, peninsula, promontory, and Gibraltar rock.

"Running in countless directions through these masses, the ocean waves appeared in narrow but doubly dark currents, forming the most crooked and irregular passages, of rivulet and river, and endless indentations of inlet and bay. Through these labyrinthine passages, perpetually opening and closing by the action of winds and waves, our escape was to be made. Once, in attempting to force a passage through a long but narrow neck of broken blocks of ice, which had drifted across our way, the cutwater, bows and wheels of the ship, were pretty seriously battered.

"All night long the ship was kept running slowly, threading her way through these little passages of clear water, until four o'clock in the morning, when she was so pressed on every side, with sheets of ice, crowded and packed far above the surface of the water,

and urged on by the momentum of vast masses of iceberg, that prudence required to stop the engine and wait for daylight. The morning brought little cheering prospect. The man at mast-head reported no clear water, as far as the eye could reach, excepting in narrow and scarcely navigable patches and veins. The surface of the sea all around the horizon, seemed an almost unbroken plain of field and mountain ice. As early as light allowed, the ship was again under way for the largest space of clear water that could be seen, and continued all day long to retrace her path to the westward, veering her course, however, through every point of the compass, to find the intricate passages toward the open sea. The wind, fresh from the north-west, came with intense and piercing cold. The man at the mast-head could not stand its severity more than half an hour. The masts, shrouds and cordage of the ship, were completely incrusted, and altogether what with field-ice, drift, and icebergs, snow, rain and hail, gale and storm, these days in the ice will not soon be forgotten.

“The different aspects of these scenes by day and night furnished an incessant source of interest. The vast fields of drift, in their varied forms, by daylight and by moonlight, were picturesque and beautiful in the highest degree. They ranged in extent from a quarter of a mile, to perhaps ten miles square. In some cases, the entire field seemed to be composed of small broken fragments, floating in close proximity to each other, yet yielding readily to the play of the waves, rising and falling with the swell of the sea. The superincumbent weight upon the surface of the water, diminished the elevation of the waves, but the reflected light from its uneven silver surface, revealed far more distinctly and beautifully, the extent of motion and the action of the waves. The long swells of the sea stretched away in graceful curves for miles, resembling more than anything else I can suggest, some of the rolling prairies of the west, as they must appear in snow, with this difference, that the swells seemed ‘all alive,’ as if some mighty monsters of the deep were working their way beneath, perpetually shifting their position, and vainly endeavoring to lift the load that covers them, to find a breathing in the open air. In other instances, these vast fields, stretching as far as the eye could reach over half the visible horizon, were one compact and apparently motionless mass of solid ice, as fixed as a ‘rock-bound coast.’

“Another form of peculiar interest was that of a wide field, of many miles in extent, apparently formed by a long succession of ‘uplifts.’ The action of the waves had gradually forced large blocks of ice beneath one edge, and the long continuation of this process, had lifted as it would seem, almost the entire mass, many feet out of water. The outer edge of these uplifts presented an abrupt and perpendicular wall. In one case, at night, the captain estimated that he had sailed for ten miles, along such a wall, the hight of the wheel-house, about forty feet. A very beautiful effect was once produced by a small mass of this kind. It was several miles distant, and of very considerable length. As it rolled and pitched, one side, apparently fifteen or twenty feet high, dipped in the waves, and rising again, lifted an immense volume of water, which then ran off, in a beautiful and magnificent torrent, over the rising edge. I watched with my glass for an hour, the graceful evolutions of this interesting cataract, which is probably still performing, by its regular rise and fall, a very respectable, but intermittent Niagara, in the middle of the Atlantic, with all the regularity of a pendulum.

“The icebergs, themselves, which we saw, were very numerous, and of almost every conceivable form and size. During our passage through three hundred miles, the number we observed was variously estimated from five hundred to one thousand. I counted at one time thirty-six, and at another forty-five, all of notable magnitude. They sometimes were of most curious and fantastic shapes. Hill and mountain of every imaginable outline, castle and tower, turret, and out-jutting and overhanging crags, magnificent needle forms shooting to the sky, like the spire of Trinity, crouching lions, and polar bears, trees of ice, and natural bridges, in short, you can scarcely fancy anything odd, that snow and ice can be made to resemble, that had not its type around us.

“But, perhaps, the most wonderful of all, was the great ‘plunging iceberg.’ It was a round, oblong mass of ice, estimated by careful comparison with our wheel-house, to be fifty by seventy-five feet. A side view made it appear about as large as the front of a large, double, four story dwelling. But it was as true and perfect an oval, as the most exquisitely beautiful bald head you have ever seen. It looked exactly like the upper part of a head of some gigantic being. This, as it floated past us, gradually descended in the waves, until it sunk beneath the surface. It then rose with a most majestic movement, lifting the pure white crown, to the hight of fifty feet. It presented on the whole, one of the grandest sights I ever beheld. It continued thus sinking and rising till it was out of our sight. It seemed like a creature of life, paying its respects to our noble ship.”

ICEBERGS.

Analogous to the ice-fields described above, are those large bodies of ice, perhaps more properly named icebergs, which fill the valleys between the high mountains in northern latitudes. Among the most remarkable, are those of the east coast of Spitzbergen. They are seven in number, and lie at considerable distances from each other, extending through tracts unknown, in a region totally inaccessible in the internal parts. The most distant of them exhibits over the sea a front three hundred feet in hight, emulating the

color of the emerald; cataracts of melted snow fall down in various parts; and black, spiral mountains, streaked with white, bound the sides, rising crag above crag, as far as the eye can reach in the background. At times immense fragments break off, and precipitate themselves into the water with a most alarming dashing. A portion of this vivid green substance was seen by Lord Mulgrave, in the voyage above referred to, to fall into the sea; and, notwithstanding it grounded in twenty-four fathoms of water, it spired above the surface fifty feet. Similar icebergs are frequent in all the arctic regions; and to their fall is owing the solid mountainous ice which infests those seas.

The frost sports wonderfully with these icebergs, and gives them majestic, as well as other most singular forms. Masses have been seen to assume the shape of a Gothic church, with arches, windows and doors, and all the rich drapery of that style of architecture, composed of what the writer of an Arabian tale would scarcely have ventured to introduce among the marvelous suggestions of his fancy, _crystals of the richest sapphirine blue_. Tables with one or more feet; and often immense flat-roofed temples, like those of Luxor, on the bank of the Nile, supported by round transparent columns of cerulean hue, float by the astonished spectator. These icebergs are the creation of ages, and acquire annually additional hight by falls of snow and rain, which latter often freezes instantly, and more than repairs the loss occasioned by the influence of the sun's heat.

LUMINOUS POINTS IN THE SEA.

Among the phenomena which have long exercised the sagacity of philosophers, that of the luminous appearance of the surface of the sea, during the obscurity of the night, is highly curious. A variety of experiments were made by a French naturalist at Cayenne, at different seasons, to ascertain its true cause; and to him it appeared that these luminous points were produced by motion and friction alone, as he could not, with the help of the best glasses, perceive any insects floating in the water. But it would seem, from the experiments and observations of many learned men, that this phenomenon is produced by various causes, both jointly and separately. It has been proved by one set of experiments, that the putrefaction of animal substances produces light and scintillation in the sea. A little white fish placed in seawater rendered it luminous in the space of twenty-eight hours. On another hand, it is certain that there is in the sea a prodigious quantity of shining insects or animalcules, which contribute to this phenomenon. A French astronomer, M. Dangelet, who returned from Terra Australis in 1774, brought with him several kinds of worms which shine in water, when it is set in motion; and M. Rigaud affirms, that the luminous surface of the sea, from Brest to the Antilles, contains a great quantity of little, round, shining polypi, of about a quarter of a line in diameter. Other learned men, who acknowledge the existence of these luminous animals, can not, however, be persuaded to consider them as the cause of all that light and scintillation which appear on the surface of the ocean. They imagine that some substance of a phosphoric nature, arising from putrefaction, must be admitted as one of the causes of this phenomenon. By other naturalists it has been ascribed to the oily and greasy substances with which the sea is impregnated; in proof of which a kind of fish, resembling the tunny, is cited, as being provided with an oil which shines with considerable luster.

The Abbe Nollent was convinced, by a series of experiments, that this phenomenon is caused by small animals, either by their luminous aspect, or by some liquor or effluvium which they emit. He did not, however, exclude other causes; and among these, the spawn or fry of fishes is deserving of attention. M. Dangelet, in sailing into the bay of Antongil, in the island of Madagascar, observed a prodigious quantity of fry, which covered the surface of the sea for the extent of more than a mile, and which he at first, on account of its color, mistook for a bank of sand. This immense accumulation of spawn or fry exhaled a disagreeable odor; and it should be remarked that the sea had, for some days before, appeared with uncommon splendor. The same accurate observer, perceiving the sea remarkably luminous in the road of the cape of Good Hope, during a perfect calm, remarked that the oars of the canoes produced a whitish and pearly kind of luster: when he took in his hand the water, which contained phosphorus, he discerned in it, for some minutes, globules of light as large as the heads of pins. On pressing these globules, they appeared to his touch like a soft and thin pulp; and some days after the sea was covered with entire banks of small fishes, in innumerable multitudes.

From all these facts it may be deduced, that various causes contribute to the light and scintillation of the sea; and that the light which the Cayenne naturalist attributed to agitation and friction, differs from that which is extended far and near, seeming to cover the whole surface of the ocean, and producing a very beautiful and striking appearance, particularly in the torrid zone, and in the summer season.

TIDES AND CURRENTS.

Alternate tides in sacred order run.—BLACKMORE.

Among the most wonderful phenomena of nature may be reckoned the tides of the sea. They were but little understood by the ancients, although Pliny, Ptolemy and Macrobius, were of opinion that they were influenced by the sun and moon. The former expressly says, that the cause of the ebb and flow is in the sun, which attracts the waters of the ocean; and he adds, that the waters rise in proportion to the proximity of the moon to the earth.

The phenomena of the tides have been ascribed to the principle of innate gravitation; but Sir Richard Phillips, in his theory of the system of the universe, refers them to that general law of motion which he considers as the primary and proximate cause of all phenomena, operating, in a descending series, from the rotation of the sun round the fulcrum of the solar system, to the fall of an apple to the earth. This motion being transferred through all nature from its source, serves as the efficient cause of every species of vitality, of every organic arrangement, and of all those accidents of body heretofore ascribed to attraction.

The waters of the ocean are observed to flow and rise twice a day, in which motion, or flux, which in the same direction lasts nearly six hours, the sea gradually swells, and, entering the mouths of rivers, drives back the river-waters toward their head. After a continued flux of six hours, it seems to repose for a quarter of an hour, and then begins to ebb, or retire back, for six hours more; in which time, by the subsidence of the waters, the rivers resume their usual course. After a quarter of an hour, the sea again flows and rises as before.

According to the theory of Newton, these phenomena were supposed to be produced by an imaginary power called attraction. The moon was supposed to attract the waters by the influence of an occult power inherent in all matter; just as the earth was supposed to attract the moon, the moon the earth, and the planets one another. Others, again, ridicule this idea, as unsustained and visionary, giving in their turn some theory that has no better argument to sustain it. And it is probable the time is yet future when we shall have any theory that will fully account for all the phenomena of the tides. On account of the shallowness of some seas, and the narrowness of the straits in others, there arises a great diversity in the phenomena, only to be accounted for by an exact knowledge of the place. For instance, in the English channel and the German ocean, the tide is found to flow strongest in those places that are narrowest, the same quantity of water being, in this case, driven through a smaller passage. It is often seen, therefore, rushing through a strait with great force, and considerably raised, by its rapidity, above that part of the ocean through which it runs.

The shallowness and narrowness of many parts of the sea, give rise also to a peculiarity in the tides of some parts of the world: for in many places, in the British seas in particular, the greatest swell of the tide is not while the moon is in its meridian hight, and directly over the place, but some time after it has declined thence. The sea, in this case, being obstructed, pursues the moon with what dispatch it can, but does not arrive with all its waters, until after the moon has ceased to operate. Lastly, from this shallowness of the sea, and from its being obstructed by shoals and straits, it happens that the Mediterranean, the Baltic and the Black sea, have not any sensible tides, to raise or depress them in a considerable degree.

Among the phenomena of the tides, one of the most singular is the bore, peculiar to several rivers: it is ascribed to the waters, which were before expansive, being suddenly pent up, and confined within a narrow space. This bore or impetuous rush of waters, accompanies the first flowing of the tide in the Ferret, in Somersetshire, and in the Seine, in France. It is also one of the peculiarities of the Severn, the most rapid river in England.

One of the greatest known tides is that of the Bristol channel, which sometimes flows upward of forty feet. At the mouth of the river Indus, the water rises thirty feet. The tides also are remarkably high on the coasts of Malay, in the straits of Sunda, in the Red sea, at the mouth of the river St. Lawrence, along the coasts of China and Japan, at Panama, and in the gulf of Bengal. The most remarkable tides, however, are those at Batsha, in the kingdom of Tonquin, in twenty degrees, fifty minutes, north latitude. In that port, the sea ebbs and flows once only in twenty-four hours, while in all other places there are two tides within that space. What is still more extraordinary, twice in each month, when the moon is near the equinoctial, there is not any tide, the water being for some time quite stagnant. These, with other anomalies of the tides there, Sir Isaac Newton, with peculiar sagacity, ascertained to arise from the concurrence of two tides, one from the South sea, and the other from the Indian ocean. Of each of these two tides there come successively two every day; two at one time greater, and two at another which are less. The time between the arrival of the two greater was considered by him as high tide; that between the two less, as ebb. In short, with these simple facts in his possession, that great mathematician solved every appearance, and so established his theory as to silence every opposer.

Besides the common and periodical tides, a variety of local currents are met with in different seas, on different parts of the ocean, and for the greater part at an inconsiderable distance from land. They have been usually ascribed to particular winds; but their

origin is not easy to trace, as they have been occasionally found beneath the surface of the water, running in a contrary direction to the stratum above, and can not, therefore, have been owing to winds or monsoons. These particular currents have been ascribed to the immense masses of polar ice, which produce a greater degree of cold in the under than in the upper stratum of waters; and it has been suspected that there is an under-current of cold water flowing perpetually from the poles toward the equator, even where the water above flows toward the poles. The great disparity of temperature which is frequently found in deep and superficial soundings of the same space of water, is thus accounted for.

The most extraordinary current of this kind, is that of the gulf of Florida, usually called the Gulf stream, which sets along the coast of North America to the northward and eastward, and flows with an uninterrupted rapidity. It is ascribed to the trade-winds, which, blowing from the eastern quarter into the great Mexican gulf, cause there an accumulation above the common level of the sea. The water, therefore, constantly runs out by the channel where it finds least resistance, that is, through the gulf of Florida, with such force as to continue a distinct stream to a very great distance. A proof of its having thus originated is, that the water in the Gulf stream has been found to have retained a great portion of the heat it had acquired in the torrid zone.

A very singular upper current often prevails to the westward of Scilly, and is highly dangerous to ships which approach the British channel. Currents of this description are, however more frequently met with about the straits of Gibraltar, and near the West India islands, the coasts of which are so subject to counter-tides, or extraordinary currents, that it is often dangerous for boats to land. They proceed to the westward, along the coasts of Yucatan and Mexico, and running round into the gulf, return into the great ocean by the straits of Bahama, along the coasts of Florida, in order to pursue, in the north, the course ordained them by the great Author of nature. In this course the waters run with an extraordinary rapidity, passing on, however, by a motion so even and imperceptible, that their speed is not realized by the spectator. But against the shores and coasts of the various islands in their way, their progress becomes very manifest, and even dangerous, interrupting the navigation, and rendering it hardly possible to stem them in their course.

In addition to these regular currents, there are others, called counter-tides, which are observable on the sea-coasts and shores. In places where these flow, the sea rolls and dashes in an extraordinary manner, becoming furious without any apparent cause, and without being moved by any wind. The waves rise and open very high, breaking on the shore with such violence, that it is impossible for vessels to land. These counter-tides have been, by some, ascribed to the pressure of the heavy black wind-clouds which are occasionally seen to hang over an island, or over the sea where they occur, though it is far more probable that in every case they are caused by under-currents and hidden shoals, by which the ordinary currents are checked and broken so as to cause the effects described.

Somewhat similar to these, at least in its hidden cause, is the celebrated Maelstrom on the coast of Norway, a view of which is given in the cut. This is caused by the tides, in their violent passage between the Loffoden islands; and its terrors, though at all times great, are sometimes greatly increased by the winds. The roar of the sea, when the Maelstrom is in full action, is said to be terrific. It is stated that not only ships, but even whales, have been sucked into this vortex, and killed by being dashed against the hidden rocks. The following description, though imaginary, gives a correct idea of the destruction of a ship in this whirlpool.

[Illustration: THE MAELSTROM.]

“The breeze, which had been long flagging, now lulled into a calm, and soon a low continual hum, like that of an army of bees, which seemed to rise out of the stilled ocean, became audible to every ear. Not a word was spoken; every one held his breath whilst he listened with an intensity of eagerness that betokened the awe that was fast filling the heart. ‘It is the Moskoestrom!’ cried the boatswain. ‘The Moskoestrom!’ echoed the crew. ‘Away, men!’ shouted the mate; ‘down to the hold, bring up the spare sails, clear the deck, set up a spar for a mast; away, away!’

“The din of preparation drowned the stern hum of the distant whirlpool: there was, however, an anxious pause when the new sail was set into the air; and experienced sailors suffered themselves to be cheated with the hope that there was still breeze enough to make the good ship answer her helm. But, alas! the heavy canvas refused to expand its folds, and not a breath of wind ruffled the dull surface of the sullen waters. They had not another hope; the sailors looked on one another with blank dismay, and now they heard, with awful distinctness, the roar of the terrible Maelstrom, and the frowning rocks of Loffoden were but too plainly visible on the right. It became evident to all, that the ship, borne along by the tide, was fast drawing near the dreadful whirlpool. The vessel continued slowly to approach, and the certainty of unavoidable death became every moment more overpowering and intense. At first the sailors stood together in a group, gazing gloomily upon one another; but as the roar of the whirlpool became louder and

louder, and the conviction of inevitable destruction became stronger, they all dispersed to various parts of the ship. * * *

“It was a beautiful day; the sun shone forth without a cloud to dim his luster, the waves sparkled beneath his influence, and the white plumage of a thousand busy sea-birds became more dazzling with his rays. The isle of Moskoe was close at hand, and looked cheerful and inviting, but the ship was not to approach nearer to its shores; the stream which bore her along never suffered any vessel to pause in its career. And now there arose at some distance ahead of the vessel, a horrible and dismal bellowing. It was the voice of the leviathan in his agony; and when those on deck who had still ears for exterior sounds looked forward to ascertain its cause, they beheld a huge black monster upon the surface of the sea, struggling against the irresistible stream, and with his immense tail lashing the waters into foam, as he vainly strove to escape from destruction. They beheld him borne away by the might of his furious enemy; and they heard his last roar above the noise of the whirlpool, as he was sucked down into the never satisfied abyss, and disappeared from their eyes to be torn to atoms; for such is the fate of everything that seeks the depths of the Maelstrom.

“The ship glides along faster and faster; she begins to toss and roll uneasily in the angry rapids that boil around her; her race is nearly run. Terrible! terrible moment! The ship hurries on to her doom with mad impetuosity. She is in the rapids! she hurries along swift as a flash of fire. She is in the whirl of water! round, round, round she goes; her inmates catch hold of her bulwarks and of each other, to steady themselves. And now her bow sprit is under the waves, and a wild shriek of despair rises into the sky! The whirlpool, with greedy jaws, has sucked her under.”

The water of the whirlpool is said to be two hundred and fifty feet deep, and at ebb its noise is as loud as a cataract. In 1645, it was so violently agitated by a storm, that in Moskoe the houses were so shaken as to cause the stones to fall to the ground. Fragments of vessels wrecked in the Maelstrom are frequently seen on the coast, brought up by the return of the tide, their edges mashed and jagged as with a saw, which would induce the belief that the bottom is composed of sharp rocks.

Similar in its cause to the Maelstrom, though on a much inferior scale, is the current, or whirlpool, called _Hurlgate_ or _Hellgate_, between the East river and Long Island sound, near New York. In the narrow channel here, the tide flows backward and forward with great force; and there being large, irregular rocks in this channel, the water is thrown into the most violent agitation. In passing through the place, it is easy to see the waves seeming to boil as if in a pot. This place is dangerous to vessels, and many have been wrecked here; though the navigation is now so well understood, that fewer accidents happen than formerly. The steamboats generally pass in safety, but still the superb Oregon got upon the rocks here, within a few years, and came near being lost.

Between Sicily and the main land are the straits of Messina, where the current is rapid. Ancient mariners deemed this a terrible place; one side they called Scylla, and the other Charybdis. The poets depicted the sailor in this rapid, as beset by horrors; for if he escaped Scylla on one side, Charybdis was ready to dash him in pieces on the other. This idea has come down to our day, and has even passed into a proverb.

CATARACTS AND CASCADES

It has often been remarked that no one is insensible to the beauty of flowing water. When it glides quietly on in a stream, its character is that of gentleness, and it suggests only the ideas of calm and tranquil beauty. But when it expands to a greater width, and its floods are poured forth in an impetuous tide, then it assumes the aspect of grandeur, and wakens in the beholder the emotions of sublimity.

The beauty of running water has, indeed, long been celebrated, and the river has often suggested an image illustrative of human life. Even Pliny, who wrote some two thousand years ago, likens a river to the progress of man. “Its beginnings,” he says, “are insignificant, and its infancy is frivolous; it plays among the flowers of a meadow, it waters a garden, or turns a mill. Gathering strength in its growth, it becomes wild and impetuous. Impatient of the restraint it meets with in the hollows of the mountains, it is restless and fretful, quick in its turnings, and unsteady in its course. Now it is a roaring cataract, tearing up and overturning whatever opposes its progress, and it shoots headlong down a rock; then it becomes a gloomy, sullen pool, buried in the bottom of

a glen. Recovering breath by repose, it again dashes along, till, tired of uproar and mischief, it quits all that it has swept along, and leaves the opening of the valley strewed with the rejected waste. Now, quitting its retirement, it comes abroad into the world, journeying with more prudence and discretion through cultivated fields, yielding to circumstances, and winding round what would trouble it to overwhelm or remove. It passes through the populous cities, and all the busy haunts of man, tenders its services on every side, and becomes the support and ornament of the country. Increased by numerous alliances, and advanced in its course, it becomes grave and stately in its motions, loves peace and quiet, and in majestic silence rolls on its mighty waters, till it is laid to rest in the vast abyss."

FALLS OF NIAGARA.

Cataracts or falls are formed by the descent of rivers over rocks, from a higher to a lower level. That of Niagara, is situated on the river Niagara, between Canada and the United States, which takes its rise in the eastern extremity of Lake Erie, and, after flowing for thirty-five miles, empties itself into Lake Ontario. Its breadth is nine hundred feet, and its depth very considerable; but its current is so exceedingly strong and irregular, and its channel so frequently interspersed with rocks, that it is navigable for small boats only. Proceeding lower, the stream widens, and the rocks gradually recede from the view, and the current though strong, is smooth and regular. At Fort Chippewa, however, situated one league above the cataracts, the scene is again changed, and the river so agitated, that a boat would be inevitably dashed in pieces, were it permitted to pass Fort Niagara, situated on its bank. So impetuously do the waves break among the rocks, that the mere sight of them, from the adjacent shore, is sufficient to strike terror in the spectator. As it approaches the falls, the stream rushes along, with redoubled fury, until it reaches the edge of the stupendous precipice, when it tumbles suddenly to the bottom, without meeting with any obstruction in its descent. Precisely at this place, the river strikes off to the right, and the line of cataracts winds obliquely across, instead of extending, in the shortest direction, from the one bank to the other. It ought to be observed, that the water does not precipitate itself down the vast abyss in one entire sheet, but, being separated by islands, forms three distinct, collateral falls.

One of these is called the great or Horseshoe fall, from the similarity of its form to that of a horseshoe. It is situated on the north-west extremity of the river, and is most deserving of the attention of the spectator, as probably seven-eighths of the water passes over it, and as its grandeur is evidently superior to that of the adjacent cataracts, although its hight may be somewhat less. As the extent of this fall can be ascertained by the eye only, it is impossible precisely to describe its limits; but its circumference is generally computed at eighteen hundred feet, somewhat more than one-third of a mile. Beyond the intervening island, the width of which may be equal to one thousand and fifty feet, is the second fall, about fifteen feet wide; and at the distance of ninety feet, occupied by the second island, is the third fall, the dimensions of which may be reckoned equal to those of the large island; so that the entire extent of the precipice, including the intermediate islands, is four thousand and five feet; a computation which certainly does not exceed the truth. The quantity of water precipitated from the falls is prodigious, and it has been estimated, amounts to _six hundred and seventy thousand, two hundred and fifty tuns per minute_.

From the eminence entitled the Table rock, the spectator has a fine prospect of the terrific rapids above the falls, and of the surrounding shores, embellished with lofty woods. He there sees to advantage the adjacent Horseshoe fall, and the dread abyss, into which he may look perpendicularly from the edge of the rock, if his courage be equal to his curiosity. The immensity of the various objects which here present themselves to the view, infallibly overwhelms a stranger with astonishment, and several minutes must elapse before he can possibly collect himself sufficiently to form any just conception of the awful and magnificent scene before him, which requires that all its component parts should be separately examined, and which affords so truly surprising an exhibition, that persons who have resided in its vicinity for several years, and who have been constantly habituated to its sublimity, ingenuously acknowledge, _at their last visit_, that they were never able before to discover its peculiar grandeur.

From a cliff nearly opposite to one extremity of the third fall, the falls are seen in a very interesting point of view: the scenery there, it is true, is less magnificent, but is infinitely more beautiful than from any other station. For several miles beneath the precipice the river is bounded, on either side, by steep and lofty cliffs, composed of earth and rocks, which in most parts are perpendicular. The descent to the bottom of the falls was formerly accomplished by two ladders, formed of long pine trees, with notches on their sides, on which the traveler rested his feet, and passed down amidst a variety of huge misshapen rocks and pendant trees, seeming to threaten him with instantaneous destruction. The breadth of the river in this part is about two furlongs; and toward the right, on the opposite side, the third fall appears in a very advantageous point of view. About one-half of the Horse-shoe fall is concealed by the projecting cliff, but its partial prospect is extremely fine. The bottom of the former of these falls is skirted with a beautiful white foam, which ascends from the rock in thick volumes, but does not rise into the air like a cloud of smoke, as is the case with that of the

latter fall, although its spray is so considerable, as to descend like a shower of rain, near the second ladder, on the opposite side of the river. On its brink, and along the strand, to the great fall, are to be constantly seen shattered trees and bodies of animals, which have been carried away by the extreme violence of the current.

The color of the water of the cataracts, as it descends perpendicularly on the rocks, is occasionally a dark green, and sometimes a foaming, brilliant white, displaying a thousand elegant variations, according to the state of the atmosphere, the hight of the sun, or the force of the wind. A portion of the spray, resulting from the falls, frequently towers above the hight, and literally mingles with the clouds: while the remainder, broken in its descent by fragments of rocks, is in continual agitation. The noise, irregularity, and rapid descent of the stream, continue about eight miles further; and the river is not sufficiently calm to admit of navigation, till it reaches Queenstown, on the west side of the river, and nine miles from the falls.

A late tourist has given us a more recent and fresh view of this wonderful cataract, which will aid us more fully to understand its various aspects as taken from different points of observation. “From the bank just below the ‘Clifton House,’ he says, “is perhaps the finest panoramic view of the falls. The general outline bears a resemblance to the shape of a human ear; the great Horseshoe fall [which is represented on the right hand of the cut below] constituting the upper lobe, while Goat island and the American fall [as seen on the left] represent the remaining portion. The river, whose general course has been east and west, makes a sharp turn to the right just at the point where the fall now is. Its breadth is here contracted from three-fourths of a mile to less than one-fourth. The Horseshoe fall only occupies the head of the chasm, while the American cataract falls over its side; so that this fall and a part of the Horseshoe lie directly parallel with the Canada shore, and its whole extent can be taken in at a single glance. It is this oneness of aspect which renders the prospect from this side so much the more impressive for a first view of Niagara. It gives a strong, sharp outline which may afterward be filled up at leisure.

[Illustration: NIAGARA FALLS.]

“The most complete view of the Horseshoe fall is that from the bottom of the cliff, at a point near the ferry landing. If, however, the water is unusually high, the quiet pool which is ordinarily seen in the foreground, becomes a fierce and angry rush of waters, foaming above and around the jagged rocks. If the water is very low, the bed of this pool is entirely dry. Last year [1852] there were but few days when the whole spot was not overflowed. The current nearest the Canada shore runs up-stream, as though seeking an outlet in the direction from which it came. The middle distance is marked by a line of white foam, beyond which the current runs downstream. The center of the Horse-shoe fall is directly in front, defined on the right by the verge of Table Rock, and on the left by the upper extremity of Goat island. Just below the tower which seems to rise from the midst of the waters on the American side, an immense mass of rock is dimly visible, which became detached from the precipice in February, 1852.

“A very charming glimpse of that portion of the fall directly in front of the tower, may be caught through a clump of trees which stand a little above the ferry landing. The limitation of view hightens the effect, when contrasted with the unlimited prospect of the fall presented from almost every other point on the Canada side.

“It is no very difficult task for a stout pedestrian to make his way along under the edge of the precipice from the ferry up to the foot of the fall. The path winds among huge fragments of rock which have tumbled from above, and is slippery with the falling spray. You stop to rest upon a huge rock, where a couple of rough-coated men are fishing. They tell you that it is named ‘Bass rock,’ and you recognize the propriety of the appellation, as you observe the finny spoil that has repaid their labor. The water rushes foaming and eddying around the fragments of rock, sometimes rising in great swells to the spot on which you stand. Fragments of timber, their ends rounded and worn like pebbles on a wave-beaten shore, are scattered around: some groaning and tossing in the water, others stranded high and dry upon the rocks, where they have been flung by some swell higher than usual. You are so near the foot of the fall that the descending sheet of water occupies the entire field of vision: the immense rock which interposes between Bass rock and the descending water has as yet received no distinctive name.

“The path now begins to ascend the sloping bank, winding around huge bowlders, and among gay shrubs which the perpetual spray nourishes in luxuriant greenness, wherever there is a resting-place for a patch of soil. At last you reach the dilapidated staircase which descends the perpendicular face of the cliff, and clambering around its base upon a rotten and slimy plank, you find yourself below the overhanging mass of Table Rock. You are close at the edge of the falling water, which descends in a mass apparently as solid as though carved from marble. You now begin to comprehend the hight of the fall. It makes you dizzy to look up to the upper edge of the rushing column. You stand just midway between the top and the bottom. Above you hangs the imminent mass of Table Rock; below, far down by the wet and jagged rocks, is the seething whirlpool, where the water writhes and eddies as

though frenzied with its fearful leap. Round and round it goes in solemn gyrations, bearing with it whatever floating object may have been plunged into its vortex.

“A year ago this very month of August, a young woman walked in the cool gray morning down to the brink of the cliff and flung herself into the whirlpool below. So resolute was the leap, that she shot clear of the jagged rocks at the base, and plunged sheer into the water beyond. When the visitors came sauntering down to the fall, her body was seen whirling round and round in the mad eddies, now submerged for an instant, and then leaping up, as though imploring aid. A day or two afterward, I was one of a group to whom a rough-looking man was describing the scene. He told how he and two others had descended amid the blinding spray close to the foot of the fall. A rope was then fastened to his body, which was held fast from above by the others, while he groped his misty way down to the very edge of the waters, where he waited till they whirled the corpse close inshore. He then darted a spear with a spring-barb into the body, but the force of the current tore out the hold, and it drifted away. Again it came within reach, and again the hold of the spear was too weak to overcome the force of the current. A third time the body approached, and the spear was darted. This time it caught among the strong muscles of the thigh, and held, so that the body was drawn to shore. The narrator was a rough man, roughly clad, and told his story roughly; but there was in his voice a low thrill of horror as he told how he was obliged to cut the spear-head out of the flesh with his knife, before the weapon could be extracted: ‘It was too bad,’ said he; ‘but it couldn’t be helped.’ And it was with unconscious pathos that he told how they stripped off their own rough garments, and tenderly covered the poor maimed and mutilated body before they bore it up the bank. It was a commentary, wrought out into practice, upon Hood’s immortal ‘Bridge of Sighs.’

“With the exception of the fall itself, the Canada side presents little of interest. The brink of the gorge is bare and naked, the trees which once clothed it having been cut away. The regular drive seems to be up to the Burning Spring, and thence back by way of Drummondville and Lundy’s Lane. At the Burning Spring you register your name, pay your fee, and are introduced into a small apartment, in the floor of which is a spring in constant ebullition from the escape of an inflammable gas. The flaxen-pated children of the show-woman place a receiver over the spring, and set fire to the gas, as it comes out of the jet; they then remove the receiver, and light the gas as it rises to the surface of the water; and that is all. You take your departure, looking vastly edified; while the driver thrusts his tongue into his cheek, as though he were mentally quoting a certain proverb touching ‘a fool and his money.’

[Illustration: Niagara Falls on the American side]

“In the early morning you commit yourself to the little boat in which you are to be ferried over to the American shore. Your half-felt misgivings are dissipated as you see the dexterous manner with which the brawny boatman handles his oars, and takes advantage of the ‘up-eddy’ and ‘down-eddy;’ and in a few minutes you are landed close at the foot of the American fall. Half-way up the ferry-stairs is an opening which gives access to a path along the foot of the perpendicular precipice to the verge of the falling water. From this point in the early morning, may be gained one of the most picturesque views of Niagara. Your position gives a fine view of the fall on the American side, as seen in the cut; the hight of which forms a standard by which you measure that of the Horseshoe fall, which stretches away in the distant perspective. Completing the ascent of the ferry-stairway, you reach Prospect point, at its head, from whence the same general view is gained, from a more elevated point. It is hard to say whether the view from above or below is the finer. The latter brings more into notice the hight of the falling column of water, thus gaining an additional element of grandeur, while the latter embraces a view of the wooded islands above the fall, adding greatly to the picturesque effect. The precise point from which the artist has taken this sketch is not now attainable. It was a projecting shelf of rock, a few feet below the precipice, which has been cut away to make room for the terribly unpicturesque, but most convenient stairway.

“This was apparently the point from which honest Father Hennepin, who has left us the earliest written account of Niagara, gazed upon that ‘prodigious Cadence of Waters, which falls down after a surprising and astonishing Manner, insomuch that the Universe can not afford its parallel.’ ‘The Waters,’ goes on the quaint narrative, ‘which fall from this horrible Precipice, do foam and boyle after the most hideous Manner imaginable, making an outrageous Noise more terrible than that of Thunder.’ The good Jesuit would seem to have been deeply moved by this ‘dismal Roaring;’ for in the curious picture which he gives of the falls, he represents the spectators holding their hands to their ears to shut out the din; and he hints that the Indians were forced to abandon the neighborhood of the falls, lest they should become deafened by the uproar. But the good father must have heard the ‘horrid Noise of the Falls,’ as he elsewhere calls it, with the imagination rather than with the ear. You hardly notice it as you loiter along the brink, except when some sudden atmospheric change varies its deep and solemn monotone. The sound is like the continuous and pervading murmur of the wind through a forest of somber pines. You are not forced to raise your voice in conversing with a friend by whose side you loiter along the brink of the fall, toward the bridge which gives you access to the wooded islands that beckon you on.

“Nothing can exceed the picturesque beauty of the small wooded islands which stud the rapids upon the American side. Two of rare beauty, known as Ship and Brig islands, stem the current a little above the bridge which connects Goat island with the shore. It needs but little effort of the imagination to fancy them vessels under full press of sail, endeavoring to sheer out of the current that hurries them inevitably down. The former of these islands is accessible by a bridge which connects it with Bath island, and is one of the loveliest spots imaginable. The old cedars, whose gnarled and contorted trunks overhang the waters, dipping their branches into the current, seem to cling with desperate clutch to the rocks, as though fearful of losing their hold and being swept away.

“From the bridge leading to Goat island, the rapids present that same appearance of plunging from the sky which renders their view from the Canadian shore so impressive. Goat island—so let it still be called, in spite of the foppery which has lately attempted to change its name to Iris island—presents an aspect almost as wild as it did before it had been rendered accessible to human foot. Were it not for the path which girdles its entire circumference, and the rustic seats disposed here and there, one might fancy that he was the first who had ever sauntered through its grand and stately woods. The beauty and variety of the trees on this island are wonderful. There is the maple, greeting the early spring sunshine with its fire-tipped buds; spreading out in summer its broad dome of dark green leaves in masses so thick, that beneath them you have no fear of the passing shower; and in autumn wearing its gorgeous crimson robe like an oriental monarch. The beech shows its dappled trunk and bright green foliage at every point, giving perpetual life and vivacity to the scene. The silvery trunks of the white birch gleam among the underwood. An occasional aspen, with its ever-quivering leaves, which almost shed a sense of breezy coolness in the stillest, sultriest day, contrasts finely with the dark evergreens by which it is relieved. Almost all of our northern fauna have their representatives here. Even upon the little Ship island, which can be crossed in any direction in a dozen strides, and which appears to a hasty view but a mass of twisted and gnarled cedars, there are at least seven distinct species of trees. Those trees, however, which immediately overhang the falls, have an aspect peculiar to themselves. They are bent, broken, twisted and contorted, in every direction. They seem to be starting back in horror from the abyss before them, and to wind their long finger-like roots around the rocks, in order to maintain their hold.

“One of these, an aged birch, growing upon the ridge known as the ‘Hog’s Back,’ affords a resting-place from which to gain one of the finest views of the American falls. Right in front is the small central fall, and the footbridge which leads to Luna island, with its trees dwarfed and stunted by the weight of frozen spray which loads them in the winter. Beyond is the serrated line of the American fall; while the distance is filled up with the receding lines of the banks of the river below.

“A few paces—past groups of blithe tourists, past companies of somber Indian girls in blue blankets and high-crowned hats, with their gay wares spread out at their feet—brings you to the Biddle staircase, down which you wind to the foot of the precipice. The path to the left leads along the foot of the overhanging cliff, up to the verge of the Horseshoe fall, only a portion of whose circumference is visible from any point on the American shore. You are here close upon the fragments of rock that fell from just in front of the tower, in February, 1852, the latest of those changes which are slowly and almost imperceptibly altering the form and position of the falls. This fall of rock was seen by an artist who has given us a faithful picture of its effects. He was just recovering from an illness, and while sitting in his room at the Clifton House, on the opposite Canadian shore, he was startled by a crash, almost like that of an earthquake. Tottering to the window, he beheld the immense curtain of rock in front of the tower precipitated from its ancient hold, and lying in huge masses upon the ice below; while a few streams of water trickled down the brown cliff, where but a moment before nothing had been seen but a surface of dazzling ice. The water at this extremity of the fall descends in light feathery forms, contrasting finely with the solid masses in which it seems to plunge down the center of the sweeping curve. The tower is perched upon the very brink of the precipice, so close that the next fall of rock must carry it along with it. The path to the right from the foot of the staircase, leads to the entrance to the Cave of the Winds, which lies behind the central fall. It is hard to imagine how this cavern missed being called the ‘Cave of Æolus,’ by those classicists who have exhausted ancient mythology for appellations for our American scenery. But it has escaped this infliction; and the ‘Cave of the Winds,’ it is, and will be. From the little house close by the entrance, where the requisite changes of dress are made, you look down into an abyss of cold gray mist, driven ever and anon like showers of hail into your face, as you grope your way down the rocky slope. Haste not, pause not. Here is the platform, half-seen, half-felt amid the blinding spray. Shade of Father Hennepin, this is truly a ‘dismal roaring’ of wind and water. We are across, and stand secure on the smooth, shaly bottom of the cave. Look up: what a magnificent arch is formed by the solid rock on the one side, and the descending mass of water on the other. Which is the solider and firmer you hardly know. Yet look again—for it is sunset—and see what we shall see nowhere else on earth, three rainbows one within another; not half-formed and incomplete, as is the scheme of our daily life, but filling up the complete circle, perfect and absolute.

“Upon an isolated rock at the very brink of the cataract stands a round tower. It is approached by a long, narrow bridge, resting now upon ledges of solid rock, and now upon loose bowlders. From the balcony upon its summit, you can lean far over the edge of the

precipice, and there catch the freshness of the cloud of spray that rises evermore from the unseen foot of the great fall. Or you can climb down the low rock upon which the tower stands, and gather shells and pebbles from within arm's length of the verge of the descent, so gentle, to all appearance, is the current. But be not over-bold. These waters, apparently so gentle, sweep down with a force beyond your power to stem. Not many months ago, a man fell from the bridge into their smooth flow, and was in the twinkling of an eye swept to the brink of the descent. Here he lodged against one of those rocks that lie apparently tottering upon the brow, looking over the fearful descent, with as little power to retrace his course, as he would have had to reascend the perpendicular fall. A rope was floated down to him, which he had just strength to fasten around his body, and he was drawn up from his perilous position.

"It is usual to speak of the Horseshoe fall as Canadian; and our rather slow neighbors across the river have been wont to plume themselves upon the possession of the more magnificent part of Niagara; while Young America has been heard to mutter between his teeth something about 'annexation,' on the ground that the lesser nation has no fair claim to the possession of the major part of the crowning wonder of the continent. But the portion of Niagara belonging to Canada is hardly worth contending for. The boundary line between the two countries is the deepest water, which runs far over toward the Canadian shore. The line passes through the lonely little isle in the center of the river, which has never been trodden by human foot. Right through the very center of the Horseshoe fall, where the water is greenest, cutting the thickest pillar of spray, through the inmost convolution of the whirlpool, through the calmest part of the quiet reach of water above the suspension bridge, through the maddest work of the rapids below, goes the boundary line, leaving to Canada nothing of Niagara except Table Rock, which yearly threatens to fall, and the half of the great fall: while to America it gives, together with full one-half of the Horseshoe fall, the varying beauties of the lesser cataracts, and the whole wealth of the lovely islands which gem the rapids.

"The general form of the falls is slowly changing from age to age. When Father Hennepin saw them, a century and three-quarters ago, they presented little of that curved and indented outline which now forms their most striking peculiarity. The fall on the western side extended in nearly a straight line from the head of Goat island to Table Rock, which terminated in a bluff that turned a portion of the water from its direct course, forming another cataract which fell to the east. A century later, this projecting rock had disappeared, but the spot which it had occupied was distinctly traceable. From the character of the strata through which the water has slowly worn its way back from the shores of Lake Ontario, we learn what must have been the appearances of the fall at any period of its history. Thus it can never have overcome the descent of three hundred and fifty feet at Lewiston at a single leap, but must have formed at least three cataracts separated by intervening rapids. When the falls occupied the position of the whirlpool, three miles below their present site, the descent was evidently greater than at any period before or since. But there never can have been a period when their beauty equaled that which they present at the present age. The immense breadth of the sheet of falling water, its graceful sweep of curves, and the picturesque islands that stud the brink, belong solely to our present Niagara. The falls recede at present, we are told, at the rate of something less than a foot in a year. Geology is able to predict that when a recession of a mile has taken place, some five or six thousand years hence, the hight of the fall will be reduced by a score of feet. Another five thousand years will subtract two score more of feet. Ten thousand years more, when the fall shall have worn its way four miles further back, all that constitutes Niagara will have disappeared, and the whole descent will be accomplished by a series of rapids like those near the whirlpool.

"It is strange how little of direct human interest is connected with Niagara. One would have supposed that it would have been a sacred spot with the Indians; but, with the exception of a few graves on the upper extremity of Goat island, no special memorial of the aborigines exists here. The falls have been known to the white race for too short a time to gather around them legendary associations. One or two points are associated with the memory of a young Englishman who, something like a score of years ago, set up as the 'Hermit of the Falls.' A picturesque little break in the rapids between Goat island and one of the rocky islets known as the Three Sisters, has been named from him the 'Hermit's cascade.' It is a lovely spot, by the side of which one may lie under the overarching trees, and while away the noontide hour, lulled into dreamy slumber by the deep voice of the cataract. This hermit seems hardly worthy of being made the hero of the falls. Little is told of him except that he was fond of music and of pacing by night along the margin of the river; that he was alike indisposed for human society and for clean linen. It is said, indeed, that he was accustomed to record his musings in Latin, but as no fragments of these were discovered after his death, we may set the story down as apocryphal. A deeper tragic interest is attached to a tale, now some three years old, which will be told you as you stand by the margin of the lesser fall. A party of visitors stood here, in gay discourse. Among them were a young man and his affianced bride, and with them a laughing child. The young man, catching up the child, said sportively to her, 'Now I shall throw you over;' when she, gliding from his hold in affright, half real and half feigned, slipped, and falling, plunged headlong into the stream; he sprang after, but the current was stronger than his strength, and swept them both down the smooth slope, and over the fall. Their

bodies, mangled and bruised, were recovered from the rocks below.

“The pedestrian can hardly find a pleasanter summer day’s ramble, than that along the river to Lewiston, descending on the American side, and returning by the opposite bank. For a mile below the falls, where the channel is narrowest, the current is so smooth, that one might fancy he was gazing down into some quiet tarn embosomed in the mountains, were it not that you catch the white margin of the lower rapids just where the suspension bridge stretches its slender line from the summits of the opposing cliffs.”

This bridge, a view of which is given in the cut below, is about two and a half miles below the falls, and spans the river near the head of the rapids, above the whirlpool. From pier to pier it is eight hundred feet long, and in breadth eight feet. It is suspended on eight wire cables, four on each side, which pass over towers fifty-four feet high, built of heavy timber. The present structure is only the scaffolding for constructing a larger bridge, intended for the passage of railroad cars. The towers for the large bridge will be of solid masonry, each eighty feet high. Each of the cables is eleven hundred feet long, and composed of seventy-two strong, No. 10 iron wires, closely wrapped round with small wire three times boiled in linseed oil, which anneals it, and prevents injury from rust or exposure to the weather. The cables, after passing over the piers on the banks, are fast anchored in solid masonry fifty feet back of them. The _suspenders_, which form the sides, are composed of eight wires each, and are four and a half feet apart. The bridge itself is two hundred feet above the water, and is a wonder alike of enterprise and art.

[Illustration: Suspension Bridge over Niagara River]

Our tourist proceeds as follows. “In the quiet reach of the water below this bridge, plies the little steamer, the Maid of the Mist. After passing the ugly, bustling little village growing up around the American extremity of the bridge, a path leads through quiet fields and woods along the very verge of the precipice. Here and there some tree growing upon the brink forms a safe balustrade over which you lean, and look down upon the green water dashing furiously through its confined channel far below.

“The whirlpool, three miles below the falls, is an adjunct worthy of Niagara. The stream makes a sharp bend just where the channel is narrowest and the descent of the rapids the steepest. At the angle the current has scooped out an immense basin, around whose whole circumference the water circles before it can find an outlet. All floating bodies that pass down the river are drawn into the whirlpool, where they are borne round and round for days, and weeks sometimes, it is said, before they make their escape. A practicable path winds down the bank to the water’s edge. The character of the banks gradually changes as we descend toward the outlet of the river. The hard limestone overlying the softer rock, and forming the perpendicular portion of the cliff, becomes thinner; the sloping talus at the foot grows higher, and the rocks are clothed with a luxurious forest growth. A half mile below the whirlpool is a deep cleft in the precipitous bank, which is connected with a wild Indian legend ascribing terrible convulsions of nature, and even the approach of the fatal white men, to an unauthorized violation of the privacy of a great demon who once abode here. This was the scene of a terrible tragedy in the old French wars. A convoy of British soldiers fell into an ambush of Indians at this point, and were all, with the exception of two, slain outright or driven over the edge of the chasm. The little rivulet which flows over the brink, ran red with the blood of the slaughtered, and thus gained the name, which it still bears, of the Bloody Run.

“Close by the Devil’s Hole, the railroad now in course of construction from Lewiston to the falls, gains the level of the top of the bank. From this point downward, it is excavated in the face of the cliff, forming a steep grade to its bottom. An almost continuous line of shanties, occupied by the laborers engaged in the excavation, extends along the very verge of the precipice. It was curious, as I passed along in the early April days, to see children whom we should scarcely trust out of the nurse’s arms, sprawling upon the very verge of the cliff. The laborers are apparently all Irish, and it is noteworthy to see how much more intelligent is the aspect of the younger than of the older children. I thought I could distinguish by their mere physical appearance, those who were born under the freer and happier auspices which surround them here. At the foot of the cliff the suspension bridge stretches like a slender thread across the stream, its supporting towers resting on a ledge above the level of the roadway. No line of guards watches the quiet frontiers of two great nations. The sole police is a small boy at the gate, and the only passport demanded is a shilling for toll. You climb the smooth slope to the summit, where the shattered monument to the noble Brock is the only memorial of the day when the thrice-won victory was at last wrenched from the hands of the Americans. A flock of sheep are cropping the tender herbage; a couple of lambs have found a shady resting-place in the crumbling archway of the monument. To the right the white village of Lewiston presents an aspect of bustling activity; while to the left, on the opposite Canadian shore, Queenstown rests gray and somber. At your feet, just below the dilapidated memorial of war, the bridge, symbol of union, binds the two shores: may it never be a pathway for the march of hostile armies!

“There are two or three things in the way of excursion which must sooner or later be performed. Some bright afternoon, when the west is all aglow, as you sit upon Table Rock, watching the clouds of spray momently torn from the face of the descending column, the guide with the hollow voice, whose mission is to conduct visitors behind the great sheet, presents himself. You commit yourself to his guidance, and donning the suit of yellow oil-skin, follow him down the spiral staircase, along the base of the precipice up to the verge of the cataract. You shudder, and hesitate to enter the blinding spray along that winding path, which seems in the dimness like a slender line drawn upon the face of the rock. The guide whispers a word of encouragement, deftly insinuating how boldly ‘the lady’ trod its slippery length. You take courage and advance. You can scarcely breathe, much less see; but you feel that the torrent is plunging from the immeasurable hight above into the unfathomable depth below. Somehow, how you hardly know, you have passed through the thick curtain of blinding spray, and are peering eagerly into the gray depth beyond. You are on Termination rock, and further than this mortal foot may never penetrate within the vail. Whichever way you turn, it is all cold gray mist, shrouding the overhanging rock and the overarching water above, and the profound depths below; all mist, cold gray mist above, below, around, except when you turn your eyes back along the path by which you entered, where you behold a strip of golden sky between the grim rock and the edge of the descending flood. Drenched and dripping, spent and exhausted, as a shipwrecked sailor flung by the surf upon some inhospitable shore, you follow your guide back along the misty path, and emerge gladly enough into the clear outer air, into the free sunshine, and beneath the bright sky. As you doff the heavy oil-skin integuments, a printed paper is put into your hand, certifying that you ‘have been under the great sheet of water, the distance of two hundred and forty feet from the commencement of the falls to the termination of Table Rock,’ verified by the signature of the proprietor of ‘Table Rock House.’ Your guide looks on you complacently, as though he would assure you that the great end of life was now attained, and you might take up your ‘=Nunc dimittis=.’

“Or you take your place upon the deck of the Maid of the Mist, hard by the suspension bridge, and are steamed up to the foot of the cataract. The little steamer answers but poorly to her romantic name. She swings wearily from her moorings, and goes panting and tugging up the current. Yet she manages to hold her course, unless the wind blows too strong down-stream, and slowly wins her way close up to the huge rocks on which the waters of the American fall are broken and shattered into the thickest of spray. In that spray a sharp and angry gust of wind tears a sudden rent, and through it you catch a glimpse of the green crest of the Horseshoe fall, sinking grandly into the ocean of vapor below. Or better still, if in some calm moonlight night, you glide, with the boatman, along the foot of the American fall, keeping just outside of the dark line of shadow, you will find there is nothing on earth so weird and ghost-like as the spectacle before you. The column of spray rises from the blackness below, like the specter of some gigantic tree, and spreads solemnly up into the clear air above.

“The mere summer tourist, however, sees but half the glory of Niagara. In the winter the great rocks at the foot of the fall are piled up with an accumulation of frozen spray to the depth of half a hundred feet. By creeping cautiously up the slippery ascent, you may stand face to face with the cataract, half-way up its giddy hight. Every shrub on its margin is loaded with glittering ice. The thick-branched evergreens are bowed beneath its weight, and bend to the ground like enormous plumes. The face of the cold gray rock is cased in the frozen element, and ribbed with pillars and pilasters which flash back the reflection of all the gems in the rays of the sun; and when in a clear, unclouded day, that sun shines down in its splendor, the scene is one of matchless magnificence and glory.”

Thus we have attempted a full description of Niagara; and yet words seem but feeble to set forth the magnificence and grandeur of the scene as it rises to the view of the actual beholder. There, in its vast volume and resistless power, it ever flows on with ceaseless, patient, unwearied tide. At midnight and noonday, through summer and winter, and seed-time and harvest, it is still the same. The drought of summer does not sensibly diminish, or the freshets of spring augment its mighty current. The scorching sun does not dry it up, and the chains of winter do not bind it. Emblem of God and of eternity, it rolls on, speaking in calm sublimity of Him who made it. Nor is sublimity the only characteristic of this greatest of waterfalls. There are traits of beauty, which seem even to highten the effect of its grandeur. The rainbow, ever playing in sunshine over its awful front, and seeming indifferent to the boiling whirlpool beneath; the tide of many-colored gems, into which the spray often seems converted, as it plunges over the rocks; the heaps of foam, white as wool, dancing on the billows that rush away from the foot of the fall; and more than all, an aspect of tranquillity and of repose, which settles upon the whole scene, when viewed at a little distance, are all incidents which blend in the majestic picture imprinted on the memory by this stupendous yet lovely work of nature’s God.

The falls of Niagara have been the frequent theme of poetry, but the following lines by Brainard are deemed the finest that have been produced upon the subject.

“The thoughts are strange that crowd into my brain, While I look upward to thee. It would seem As if God poured thee from his ‘hollow hand,’ And hung his bow upon thine awful front; And spoke in that loud voice, which seemed to him Who dwelt in Patmos for his Saviour’s sake, ‘The sound of many waters;’ and had bade Thy flood to chronicle the ages back, And notch His centuries in the eternal rocks!

“Deep calleth unto deep, and what are we, That hear the question of that voice sublime? Oh! what are all the notes that ever rung From war’s vain trumpet, by thy thundering side! Yea, what is all the riot man can make In his short life, to thine unceasing roar! And yet, bold babbler, what art thou to Him, Who drown’d a world, and heaped the waters far Above its loftiest mountains?—a light wave, That breaks and whispers of its Maker’s might!”

FALLS OF THE MONTMORENCI.

The Montmorenci empties itself at the distance of about eight miles northeast of Quebec, into the great river St. Lawrence, to the coast of which it gradually descends from the elevated mountain on which it has its source. At a station called La Motte, situated on the northern extremity of a sloping ground, its waters diffuse themselves into shallow currents, interrupted by rocks which break them into foam, and accompanied by murmuring sounds which enliven the solitude and solemn stillness prevailing throughout the surrounding forests and desolate hills. Further down, its channel is bounded by precipitous rocks, its breadth becoming extremely contracted, and the rapidity of its current proportionably augmented. At a place called “the natural steps,” there are several beautiful cascades of ten or twelve feet. These steps, which are extremely regular, have been gradually formed by the accession of waters the river receives in its progress, at the breaking up of winter, by the melting of the snows. From the middle of April to the end of May, its waters roll with increasing hight and rapidity. Being powerfully impelled in their course, they insinuate themselves between the strata of the horizontal rock, vast fragments of which are detached by the rushing violence of the sweeping torrent.

[Illustration: FALLS OF MONTMORENCI.]

On the eastern side, the bank, which is almost perpendicular, and fifty feet high, is surmounted by lofty trees. The south-west bank rises beyond the steps, and terminates in a precipice. On the opposite side, the bank is regular, and of a singular shape, resembling the ruin of an elevated wall. The trees by which the banks are inclosed, united with the effect produced by the foaming currents, and the scattered masses of stone, form a scene wild and picturesque. The stream now taking a southern direction, is augmented in its velocity, and forms a grand cascade interrupted by huge rocks. A quarter of a mile further down a similar effect is produced. After exhibiting an agreeable variety through its course, the river is precipitated, in an almost perpendicular direction, over a rock two hundred and fifty feet in hight. A view of this latter cascade is given in the cut. Wherever it touches the rock, it falls in white clouds of rolling foam; and, beneath, where it is propelled with uninterrupted gravitation, it forms numerous flakes, like wool or cotton, which are gradually protracted in the descent, until they are received into the boiling profound abyss beneath.

The effect from the summit of the cliff is awfully grand, and truly sublime. The prodigious depth of the descent of the waters of this surprising fall; the brightness and volubility of their course; the swiftness of their movement through the air; and the loud and hollow noise emitted from the basin, swelling with incessant agitation from the weight of the dashing waters, forcibly combine to attract the attention, and to impress the mind of the spectator with sentiments of grandeur and elevation. The clouds of rising vapor, which assume the prismatic colors, contribute to enliven the scene. They fly off from the fall in the form of a revolving sphere, emitting with velocity pointed flakes of spray, which spread in receding, until they are interrupted by the neighboring banks, or dissolved in the atmosphere.

The breadth of the fall is one hundred feet; and the basin, which is bounded by steep cliffs, forms an angle of forty-five degrees. When viewed from the beach, the cataract is seen, with resplendent beauty, to flow down the gloomy precipice, the summit of which is crowded with woods. The diffusion of the stream, to the breadth of fifteen hundred feet, and the various small cascades produced by the inequalities of its rocky bed, on its way to the river St. Lawrence, display a very singular and pleasing combination.

THE TUCCOA FALL.

This fall, in Franklin county, Georgia, is as yet scarcely known to the best informed of our geographers, and is notwithstanding one of the most beautiful that can be conceived. It is much higher than the great fall of Niagara; and the water is charmingly propelled over a perpendicular rock. When the stream is full, it passes down the steep in one expansive sheet, magnificent to behold.

FALLS OF THE MISSOURI.

The most prominent features of this great river, which is fed by so many streams, having their sources in a great variety of soils and climates, are its wonderful falls, rapids and cascades, the following connected view of which is abstracted from the very accurate draught and survey made by Captain Clarke.

This river is nine hundred feet wide at the point where it receives the waters of Medicine river, which is four hundred and one feet in width. The united current continues five thousand, four hundred and twelve feet, somewhat more than a mile, to a small rapid on the north side, from which it gradually widens to four thousand, two hundred feet, and at the distance of nine thousand and forty-two feet, (nearly a mile and three-fourths,) reaches the head of the rapids, narrowing as it approaches them. Here the hills on the north, which had withdrawn from the bank, closely border the river, which, for the space of a mile, makes its way over the rocks with a descent of thirty feet: in this course the current is contracted to sixteen hundred and forty feet, and, after throwing itself over a small pitch of five feet, forms a beautiful cascade of twenty-six feet, five inches; this does not, however, fall quite perpendicularly, being stopped by a part of the rock, which projects at about one-third of the distance. After descending this fall, and passing the Cotton-wood island, on which the eagle has fixed its nest, the river goes on for eight thousand, seven hundred and seventy-eight feet, (more than a mile and a half,) over rapids and little falls, the estimated descent of which is thirteen feet six inches, till it is joined by a large fountain boiling up underneath the rocks near the edge of the river, and falling into it with a cascade of eight feet. It is of the most perfect clearness, and rather of a bluish cast; and even after falling into the Missouri it preserves its color for half a mile. From this fountain the river descends with increased rapidity for the distance of thirty-five hundred and thirty-one feet, during which the estimated descent is five feet: from this, for a distance of twenty-two hundred and twenty-seven feet, the river descends fourteen feet seven inches, including a perpendicular fall of six feet seven inches. The river has now become pressed into a space of fourteen hundred and nineteen feet, and here forms a grand cataract, by falling over a plain rock, the whole distance across the river, to the depth of forty-seven feet, eight inches: after recovering itself, the Missouri then proceeds with an estimated descent of three feet, till at the distance of sixteen hundred and eighty-three feet it again is precipitated down the crooked falls, nineteen feet perpendicularly; below this at the mouth of a deep ravine, is a fall of five feet, after which, for the distance of sixteen thousand and five feet, (upward of three miles,) the descent is much more gradual, not being more than ten feet, and then succeeds a handsome level plain for the space of twenty-nine hundred and thirty-seven feet, (more than half a mile,) with a computed descent of three feet, making a bend toward the north. Thence it descends, during seventy-nine hundred and twenty feet, about eighteen feet and a half, when it makes a perpendicular fall of two feet, which is fourteen hundred and eighty-five feet beyond the great cataract, in approaching which it descends thirteen feet, within a distance of about six hundred feet, and gathering strength from its confined channel, which is only eight hundred and forty feet wide, rushes over the fall to the depth of eighty-seven feet and three-quarters of an inch. After raging among the rocks, and losing itself in foam, it is compressed immediately into a bed of two hundred and seventy-nine feet in width; it continues for fifty-six hundred and ten feet to the entrance of a run or deep ravine, where there is a fall of three feet, which, joined to the decline of the river during that course, makes the descent six feet. As it goes on, the descent within the next thirty-nine hundred and sixty feet is only four feet; from this, passing a run or deep ravine, the descent for sixteen hundred feet is thirteen feet: within thirty-nine hundred and sixty feet, is a second descent of eighteen feet; thence twenty-six hundred and forty feet further, is a descent of six feet; after which, to the mouth of Portage creek, a distance of forty-six hundred and twenty feet, the descent is ten feet. From this survey and estimate it results that the river experiences a descent of three hundred and fifty-two feet in the course of fifteen or sixteen miles, from the commencement of the rapids, to the mouth of Portage creek, exclusive of almost impassable rapids which extend for a mile below its entrance.

CATSKILL FALLS.

The Catskill, or Kauterskill falls, represented in the cut below, are in the south-west part of the town of Catskill, about fourteen miles from the village, and two miles west from Pine Orchard, a celebrated summer resort on the brow of the Catskill mountain. Two ponds, uniting their outlets, pour the stream thus formed, by falls and rapids in a deep ravine, to the plain below. The first fall is a hundred and eighty feet perpendicular; and the second, which is within a short distance, about eighty feet. Behind the first fall is an immense natural amphitheater, into which the visitor can go, and look through the water as it falls from above. The view from the ‘Mountain house,’ near by, is extensive and varied. The landscape, in a clear atmosphere, is visible for sixty miles.

[Illustration]

TRENTON FALLS.

Among the most beautiful and romantic cascades of the United States, may justly be reckoned Trenton falls, situated about eighteen miles north-east of Utica, in the state of New York, on West Canada creek. Here, within a course of two miles, there are

six falls, with an aggregate descent of three hundred and twelve feet. The scenery is the most wild and picturesque imaginable; the stream flowing through a narrow ravine, between perpendicular walls of limestone, which in some places are one hundred and fifty feet high. The pathway of the spectator is mostly along the very margin of the chasm which forms the channel of the rushing waters, on a ledge, or shelf, so narrow and perilous, that the head often is giddy from the sight; and sometimes it is difficult to sustain one's self. These cascades are more remarkable for the wildness and variety of scenery, than for the volume of water they present. The hight of the principal fall is estimated at one hundred feet.

WATERFALL OF SOUTH AFRICA.

The great chain of mountains which runs from north to south through the colony of the Cape of Good Hope, divides into two branches, one of which stretches south-east, and the other due south. At the extremity of the latter branch is "the waterfall mountain," in one of the clefts of which a large stream of water falls from the high rock above, and presents, in the winter season, when swollen by the rains, a glorious spectacle. To view this fall to advantage, the traveler has to climb to a considerable hight over the steep and broken rocks which form one side of the mountain, and, on reaching the top, sees it on the other side. Its hight is estimated at between eighty and ninety feet, and its breadth at between thirty and forty. Adequate terms can not be found to describe the sublimity of this scene, after abundant rains, when it is in its full beauty. In the vale beneath, the water is collected in a vast and deep basin, excavated in the stone; and by the side of the stream is a grotto, which runs within the rock to the depth of between thirty and forty feet. The arched entrance to this grotto is close to the falling water, when the stream is full. The rocks about it are thickly grown over with shrubs, which are then sprinkled by the spray. The European travelers who proceed from Cape Town to the interior of South Africa, seldom fail to make a pilgrimage to this enchanting spot.

CATARACTS OF THE NILE.

This celebrated river, through its long and fertile range of about two thousand British miles, in winding through abrupt and precipitous countries, exhibits very considerable cataracts, ten or twelve of which, having a descent of more than twenty feet, occur, before it reaches the level of Egypt. The one which, by way of eminence, is called the cataract of the Nile, was visited by Mr. Bruce, from whose relation the following particulars are extracted.

At the distance of half a mile beneath the cataract, the river is confined between two rocks, over which a strong bridge of a single arch has been thrown, and runs into a deep trough, with great roaring, and an impetuous velocity. On ascending, the cataract presents itself amid groves of beautiful trees, and exhibits a most magnificent and stupendous sight, such as, Mr. Bruce observes, ages, added to the greatest length of human life, could not efface or eradicate from his memory. It struck him with a kind of stupor, and total oblivion of where he was, as well as of every sublunary concern. At the time of his visit, the river had been considerably increased by rains, and fell in one sheet of water, above half an English mile in breadth, and to the depth of at least forty feet, with a force and noise which were truly terrific, and which, for a time, stunned him, and made him giddy. A thick fume, or haze, covered the fall in every part, and hung over the course of the stream both above and below, marking its track, although the waters were not seen. The river, although much swollen, preserved its natural clearness, and fell, partly into a deep pool, or basin, in the solid rock, and partly in twenty different eddies to the very foot of the precipice. In falling, a portion of the stream appeared to run back with great fury on the rock, as well as forward in the line of its course, raising waves, or violent ebullitions, which chafed against each other.

CATARACT OF THE MENDER.

The cataract which constitutes the source of this river, the Scamander of the ancients, is thus beautifully described by Doctor Clarke. "Our ascent, as we drew near to the source of the river, became steep and rocky. Lofty summits towered above us, in the greatest style of alpine grandeur; the torrent, in its rugged bed below, all the while foaming on our left. Presently we entered one of the sublimest natural amphitheaters the eye ever beheld; and here the guides desired us to alight. The noise of waters silenced every other sound. Huge craggy rocks rose perpendicularly, to an immense hight; whose sides and fissures, to the very clouds, concealing their tops, were covered with pines. These grew in every possible direction, among a variety of evergreen shrubs; and enormous plane-trees waved their vast branches above the torrent. As we approached its deep gulf, we beheld several cascades, all of foam, pouring impetuously from chasms in the naked face of a perpendicular rock. It is said the same magnificent cataract continues all seasons of the year, wholly unaffected by the casualties of rain or melting snow. Having reached the chasms whence the torrent issues, we found, in their front, a beautiful natural basin, six or eight feet in depth, serving as a reservoir for the water during the first moments of its emission. It was so clear that the minutest object might be discerned at the bottom. The copious

overflowing of this reservoir causes the appearance, to a spectator below, of different cascades, falling to the depth of about forty feet, but there is only one source. Behind are the chasms whence the water issues. We entered one of these, and passed into a cavern. Here the water appeared, rushing with great force, beneath the rock, toward the basin on the outside. The whole of the rock about the source was covered with moss; close to the basin grew hazel and plane trees; above were oaks and pines; and all beyond a naked and fearful precipice."

The bold and precipitous country of the Alps offers a variety of waterfalls and perpendicular torrents which are well deserving of notice; more particularly those in the vicinity of Mount Rosa, a part of the northern boundary of Piedmont. The river Oreo, fed by numerous streams from Mount St. Gothard, Mount Cenis, and several branches of the Apennines, forms, at Cerosoli, a vertical cascade, estimated at four hundred fathoms, or twenty-four hundred feet; while the torrent Evanson, descending from another part of Mount Rosa, exhibits a fall of more than two hundred fathoms, rolling down pebbles of quartz, veined with the gold which is occasionally traced in the mountains of Challand. The Cascata del Marmore, or Marble Cascade, so denominated from the mountain down which the Velcino falls being almost wholly of marble, lies about three miles from Terni. In proceeding toward it, the traveler is struck with terror on viewing the precipices, which are of a romantic hight; but is sufficiently rewarded, when, on reaching the summit of the mountain, he regards the stupendous cataract, formed by the river as it rushes from the mountain. Having reached the declivity of its channel, the waters descend with a rapid course for a short space, and then fall from a perpendicular hight of three hundred feet, breaking against lateral rocks, which cause vapors to ascend much higher than the summit of the cataract, by which the neighboring valley receives a perpetual fall of rain. After this descent, the waters rush into the cavities of the rocks, and then bursting through several openings, at length reach the bed of the river.

The grand cascade of the Anio, near Tivola, flows down the edge of a steep rock; and at its foot, the water, in a succession of ages, has hollowed grottos of various shapes and sizes, in a manner so beautifully picturesque, as to baffle all description. Of these, the grotto of Neptune is the most celebrated. Near to it are three smaller cascades, which rush murmuring through the ruins of the villa Mecænas, down the woody steep which forms the opposite bank of the river, and present the painter with one of the most picturesque views imaginable, the foreground varying beautifully at every step he takes.

In Savoy, the Arve flows many miles between high, craggy and inaccessible rocks, which appear to have been purposely cleft to give its waters a free passage. The surprising echoes and continual sounds occasioned by its streams, the trampling of the horses and mules, the hallooing of passengers, &c., are, in these places, reverberated three, four, and even in some parts six or seven times, with a noise so deep and wild, as to strike with terror the traveler who is unaccustomed to them; and the firing of a gun or pistol, is there more terrible than the loudest claps of thunder. A steep precipice, with monstrous impending rocks, which seem ready to fall, joined to the roaring of the river, add largely to the general sublimity. The cataracts of this river are more or less loud and terrible, in proportion as the waters are more or less swollen by the melting snows, with which the tops of the mountains are covered. One in particular, called the Nun of Arpena, falls from a prodigiously high rock with great noise and violence: its descent is said to exceed eleven hundred feet.

In Dalmatia, the river Cettina forms a magnificent cascade, called by the inhabitants Velica Gubavisa, to distinguish it from a less fall a little below. The waters precipitate themselves from a hight of above one hundred and fifty feet, forming a deep majestic sound, which is caused by the echo resounding between the steep and naked marble banks. Many broken fragments of rocks, which impede the course of the river after its fall, break the waves, and render them still more lofty and sonorous. By the violence of the repercussion, their froth flies off in small white particles, and is raised in successive clouds, which are scattered, by the agitation of the air, over the valley. When these clouds ascend directly upward, the inhabitants expect the noxious south-east wind called the sirocco.

The fall of the Staub-Bach, in the valley of Lauterbrannen, is estimated at nine hundred feet of perpendicular hight; and about a league from Schaffhausen, at the village of Lauffen, in Switzerland, is a tremendous cataract of the Rhine, where that river precipitates itself from a rock said to be seventy feet in hight, and not less than four hundred and fifty feet broad.

In Sweden, near Gottenburgh, the river Gotha rushes down from a prodigiously high precipice into a deep pit, with a dreadful noise, and with such amazing force, that the trees designed for the masts of ships, which are floated down the river, are usually turned upside down in their fall, and shattered in pieces. They frequently sink so far under water, as to disappear for a quarter of an hour, half an hour, and sometimes for three-quarters of an hour. The pit into which the torrent precipitates them, is of a depth not to be ascertained, having been sounded with a line of several hundred fathoms, without the bottom being found.

In addition to the other North American cataracts already described, may be noticed the Passaic falls, formed by the river Passaic, which discharges itself into the sea at the northern extremity of the state of New Jersey. About twenty miles from the mouth of this river, where it has a breadth of about a hundred and twenty feet, and runs with a very swift current, it reaches a deep chasm, or cleft, which crosses its channel, and falls about seventy feet perpendicularly in an entire sheet. One end of the cleft is closed up, and the water rushes out of the other with incredible rapidity, in an acute angle to its former direction, and is received into a large basin. It thence takes a winding course through the rocks, and spreads again into a very considerable channel. The cleft is from four to twelve feet in breadth, and is supposed to have been produced by an earthquake. The falls of St. Anthony, on the river Mississippi, descend from a perpendicular hight of thirty feet, and are nearly eight hundred feet in width, while the shore on each side is a level flat, without any intervening rock or precipice.

In England, among the cataracts which merit a brief mention, may be cited the one in Devonshire, near the spot where the Tamer receives the small river Lid. The water there falls above a hundred feet: it proceeds from a mill at some distance, and after a course on a descent of nearly one hundred feet from the level of the mill, reaches the brink of the precipice, whence it falls in a most beautiful and picturesque manner, and, striking on a part of the cliff, rushes from it in a wider cataract to the bottom; where falling again with great violence, it makes a deep and foaming basin in the ground. This fine sheet of water causes the surrounding air at the bottom to be so impregnated with aqueous particles, that those who approach it find themselves in a mist. In Cumberland there are several cataracts; but these are exceeded in beauty by a remarkable fall of the Tees, on the western side of the county of Durham, over which is a bridge suspended by chains, seldom passed unless by the adventurous miners. Asgarth force, in Yorkshire, is likewise a very interesting fall.

In Scotland, the fall of Eyers, near Loch Ness, is a vast cataract, in a darksome glen of a stupendous depth. The water rushes beneath, through a narrow gap between two rocks, and thence precipitating itself more than forty feet lower into the bottom of the chasm, the foam, like a great cloud of smoke, rises and fills the air. The sides of this glen are stupendous precipices, blended with trees overhanging the water, through which, after a short space, the waters discharge themselves into the lake. About half a mile to the south of this fall, is another which passes through a narrow chasm, whose sides it has undermined for a considerable distance. Over the gap is a true alpine bridge, formed of the trunks of trees covered with sods, from the middle of which is an awful view of the water roaring beneath. In Perthshire, the river Keith presents a very considerable cataract, the noise produced by which is so violent as to stun those who approach it. The western coast of Ross-shire is, however, peculiarly distinguished by these natural wonders, among which may be cited the grand cataract of the river Kirkag, and the cascade of Glamma, which latter being situated amid the constant obscurity of woody hills, is truly sublime.

In Ireland, the noble river Shannon has a prodigious cataract, which, at about fifty miles from its mouth, prevents it from being longer navigable for vessels of a large burden.

SPRINGS AND WELLS.

ST. WINIFRED'S WELL.

Holywell, in Flintshire, is famous for St. Winifred's well, one of the finest springs in the world. On account of the sanctity in which it was holden, it gave name to the town. This well pours out, each minute, _twenty-one tuns of water_, which, running to the middle of the town, down the side of a hill, is made use of by every house as it passes, after which it turns several mills, and is employed in various manufactures, which greatly increase the population of the place and its neighborhood. Over the spring, where a handsome bath has been erected, is a neat chapel, supported by pillars, and on the windows are painted the chief events of St. Winifred's (or, as it was anciently written, Wenefrede's) life. About the well grows moss, which the ignorant and superstitious devotees most stupidly imagine to be St. Winifred's hair. This saint is reported to have been a virgin martyr, who lived in the seventh century, and, as the legend says, was ravished and beheaded in this place by a pagan tyrant; the spring having miraculously risen from her blood. Hence this bath was much frequented by popish pilgrims, out of devotion, as well as by those who came to bathe in it for medicinal purposes. Mr. Pennant says, "The custom of visiting this well in pilgrimage, and offering up devotions there, is not yet entirely laid aside: in the summer a few are to be seen in the water, in deep devotion, up to their chins for hours, sending up their prayers, or performing a number of evolutions round the polygonal well."

It might have been supposed that the present enlightened age would have been secure against a repetition of impostures of this kind; but Doctor Milner, a Catholic bishop, of Wolverhampton, took much pains to persuade the world that an ignorant proselyte, of the name of Winefrid White, was there cured of various chronic diseases, so late as the year 1804, by a miracle. Sir Richard

Phillips, having, in the Monthly Magazine, referred this pretended miracle to the known effect of strong faith on ignorant minds, in any proposed means of cure, was attacked by the Catholic clergy for his incredulity; but in number three hundred and two, of the Monthly Magazine, he replies in the following words.

“We have no doubt whatever that Winefrid White was cured by her journey to Holywell, and by bathing in the wonderful natural spring at that place; but we are not credulous enough to believe that her cure was effected by any antagonist properties of the water to the cause of her disease; nor impious enough so to sport with eternal omnipotence, as to assert that a capricious suspension of the laws of nature took place for this purpose. On the contrary, we believe that the poor woman was cured by causes well known to every medical practitioner, and proved in hundreds of recorded instances; that is to say, by her faith in the means proposed for her cure, wrought to the highest pitch by her religion, and by the assurances of those to whom she was accustomed to defer. We think, nevertheless, that the publication of this ‘case of Winefrid White,’ savors strongly of religious empiricism, and is exactly analogous to the ‘cases of cure’ which we every day see advertised in all the newspapers. We refrain from treating the subject theologically, yet it appears to us that Matthew xxiv. 24, proves that ‘signs and wonders’ are not only no evidence of divine interposition, but may be used even by ‘false prophets, so as to deceive the very elect.’ The continuance of miraculous powers will be found, we suspect, to depend on other circumstances than the date of the year. They disappear wherever the printing-press begins to be freely used, and, by its agency, fixes all the circumstances that attend them; and they still continue to flourish wherever the history of the circumstances depends for any period on traditional evidence. Miracles are, therefore, performed in abundance, even in our days, among the negroes, the Hottentots, the Caffres, the Tartars, the South Sea islanders, and the Indians of the two Americas. The last we believe on record are to be found in the Hon. M. Elphinstone’s published embassy to Cabul in 1808: he states that the sick were carried after him many days’ journey; and, at page twenty-eight, he says: ‘Some thought we could raise the dead; and there was a story current, that we had made and animated a wooden ram at Mooltaun; that we had sold him as a ram; and that it was not till the purchaser began to eat him, that the material of which he was made was discovered.’ We forbear to press the subject further.”

WIGAN WELL.

About a mile from Wigan, in Lancashire, is a spring, the water of which burns like oil. On applying a lighted candle to the surface, a large flame is suddenly produced, and burns vigorously. A dishful of water having been taken up at the part whence the flame issues, and a lighted candle held to it, the flame goes out; notwithstanding which the water in this part boils and rises up like water in a pot on the fire, but does not feel warm on introducing the hand. What is still more extraordinary, on making a dam, and preventing the flowing of fresh water to the ignited part, that which was already there having been drained away, a burning candle being applied to the surface of the dry earth at the same point where the water before burned, the fumes take fire, and burn with a resplendent light, the cone of the flame ascending a foot and a half from the surface of the earth. It is not discolored, like that of sulphureous bodies, neither has it any manifest smell, nor do the fumes, in their ascent, betray any sensible heat. The latter unquestionably consist of inflammable air, or hydrogen gas; and it ought to be observed that the whole of the country about Wigan, for the compass of several miles, is underlaid with coal. This phenomenon may therefore be referred to the same cause which occasioned the dreadful explosion of Felling colliery; but in the present case, this destructive gas, instead of being pent up in the bowels of the earth, accompanies the water in its passage to the surface.

DROPPING WELL AT KNARESBOROUGH.

This dropping well, or petrifying spring, rises at the foot of a limestone rock, at an inconsiderable distance from the bank of the river Nidd. The spring, after running about sixty feet, divides, and spreads itself over the top of the rock, whence it trickles very fast, from thirty or forty places, into a channel hollowed for the purpose, as seen in the cut, each drop producing a musical kind of tinkling, probably owing to the concavity of the rock, which, bending in a circular projection from the bottom to the top, occasions its brow to overhang about fifteen feet. This rock, which is about thirty feet in hight, forty-eight in length, and from thirty to fifty in breadth, started, in the year 1704, from the common bank, and left a chasm, from five to nine feet wide, over which the water passes by an aqueduct formed for the purpose. It is clothed with evergreen and other shrubs, which add greatly to the beauty of this very interesting scene.

[Illustration: DROPPING WELL AT KNARESBOROUGH.]

The water is said to abound with fine particles of a nitrous earth, which it deposits, but when in a languid motion only, and leaves its incrustations on the leaves, moss, &c., which it meets with, in trickling thus slowly through the cavities of the rock. This spring is

estimated to send forth twenty gallons of water in a minute. Here are to be seen pieces of moss, bird's nests with their eggs, and a variety of other objects, some of them very curious which have been incrusted or petrified by the water.

BROSELEY SPRING.

This celebrated boiling spring, or well, at Broseley, in Shropshire, was discovered in the month of June, 1711. It was first announced by a terrible noise in the night, there having been a remarkable thunder-storm. Several persons who resided in the vicinity having been awakened in their beds by this loud and rumbling noise, arose, and proceeding to a bog under a small hill, about two hundred yards from the river Severn, perceived a surprising commotion and shaking of the earth, and a little boiling up of water through the grass. They took a spade, and digging up a portion of the earth, the water immediately flew up to a great hight, and was set on fire by a candle which was presented to it. To prevent the spring from being destroyed, an iron cistern has been placed over it, provided with a cover, and a hole in the center, through which the water may be viewed. If a lighted candle, or any burning substance, be presented to this aperture, the water instantly takes fire, and burns like spirit of wine, continuing to do so as long as the air is kept from it; but on removing the cover of the cistern, it quickly goes out. The apparent boiling and ascent of the water of this spring, are still more obviously the result of hydrogen gas, or inflammable air, than in the preceding instance of Wigan well.

HOT SPRINGS OF ST. MICHAEL.

In the eastern part of this island, (one of the Azores,) is a round, deep valley surrounded by high mountains, in which are many hot springs; but the most remarkable is that called the Caldeira, situated in the eastern part of the valley on a small eminence by the side of a river, on which is a basin about thirty feet in diameter, where the water continually boils with prodigious fury. A few yards distant from it, is a cavern in the side of a bank, in which the water boils in a dreadful manner, throwing out a thick, muddy, unctuous water, several yards from its mouth, with a hideous noise. In the middle of the river are several places where the water boils with so intense a heat, that a person can not dip his finger into it without being scalded. On its banks are several apertures, out of which the steam rises to a considerable hight, and is so hot that it can not be approached by the hand. In other parts, the spectator would be led to suppose that the bellows of a hundred forges were blowing in concert; while sulphureous streams issue out in a thousand places. The bushes even, near these spots, are covered with pure brimstone, condensed from the steam which issues from the ground. In the small caverns whence the steam issues, many of the inhabitants prepare their food.

HOT SPRINGS OF THE TROAD.

The Troad, a country of Phrygia, in Asia Minor, of which Troy was the capital, abounds with hot springs; the most interesting one of which is thus described by Doctor Clarke. It is situated near a place called Bonarbashy, signifying literally "the head of the springs," and gushes perpendicularly out of the earth, rising from the bottom of a marble and granite reservoir, and throwing up as much water as the famous fountain of Holywell, in Wales. Its surface seems vehemently boiling; and, during cold weather, the condensed vapor above it causes the appearance of a cloud of smoke over the well. While the mercury stood at forty-six degrees in the open air, it rose, when the thermometer was plunged in the water, to sixty-two degrees. Notwithstanding the warmth of this spring, fishes were seen sporting in the reservoir. In every part of the district through which the Mender flows, from Ida to the Hellespont, are many of these springs, of different degrees of temperature.

The Geysers have already been described, in treating of Mount Hecla, and its surprising volcano. In following up the details of the phenomena of this nature given above, by a brief notice of other bubbling, tepid and boiling springs, it may not be improper to premise that heat, water and vapors of various kinds, exist in prodigious quantities beneath the surface of the earth; and frequently, as has been seen in the phenomena of volcanoes and earthquakes, burst forth from enormous openings, with tremendous destruction. It often happens, however, that the openings are small and porous, and that the vapors ascending through them, are simply combined with water. Hence that almost infinite variety in the characters of these springs, fountains and lakes, the waters of which are combined with extraneous substances. In some cases the clastic gases, or vapors, ascend from specific levity alone, and are destitute of all taste and odor; insomuch that springs are found which bubble without boiling, or betraying heat or any other foreign quality. In other cases they are strongly impregnated with heat; and are then either tepid or boiling, according to the proportion of extricated caloric they contain. Occasionally, whether hot or cold, they are blended with metallic, sulphureous, saline, and other substances, and hence assume the name of mineral waters; while, if the substance thus dissolved be combustible, as naphtha, bitumen, or turpentine, the fountain will often inflame and burn on the application of a lighted torch.

The water of the noted boiling spring at Peroul, near Montpelier, is observed to heave and boil up very furiously in small bubbles, which manifestly proceed from a vapor breaking out of the earth, and rushing through the water, so as to throw it up with noise, and in many bubbles; for on digging in the vicinity of the ditch where the spring lies, and pouring fresh water on the dry spot newly dug, the same boiling is immediately observed. A similar bubbling of the water is likewise found near Peroul, on the seashore. In several dry places near the spring, are small ventiducts, passages or clefts, whence steam issues; and at the mouths of these passages, small light bodies, such as feathers, pieces of straw, leaves, &c., being placed, are soon blown away. This vapor, on the application of a lighted candle or torch, does not flame or take fire, as is the case with that of the boiling spring at Wigan; so that there are two different sorts of steam, to occasion these boilings, at the same time that neither of the fountains is medicinal, or even warm.

Other boiling waters, of a very different temperature, possess, like those of the hot springs of St. Michael, a sufficient degree of heat to boil eggs, and to serve for other culinary purposes. Among these may be instanced those of the Solfatara, near Naples; those on the summit of Mount Zebio, in the Modenese territory; and those which constitute the source of the imperial bath at Aix la Chapelle. In Japan, a hot spring is said to burst forth which constantly maintains the boiling-point, and the water of which retains its heat much longer than common water. It does not flow regularly, but during an interval of two hours each day; and the force and violence of the vapors are then so great, that large stones are ejected, and raised to the hight of ten or twelve feet, with a noise like that of the explosion of a piece of artillery.

From the phenomena which have been adduced, it appears that the exhalations constantly escaping from the vast subterraneous magazines in which they are prepared, vary greatly in their qualities and effects. Some are cold and dry, resembling air or wind, as those near Peroul, and in the cavities of mountains, especially those of Æolus and other hills of Italy, as well as in particular mines. Others are inflammable, and of a bituminous nature, though not positively warm, as those of Wigan well. Others are very hot, sulphureous and saline, more especially those of the natural stoves, sweating-vaults, grottos, baths and volcanoes near Naples, Baiæ, Cuma and Pozzuoli, as also in some of the subterraneous works at Rome. And others, again, are of an arsenical, or other noxious quality, as those of the Grotta del Cane. Now, these various streams meeting with, and running through water, must occasion in it a great variety of phenomena and effects.

It is observed by Doctor Thomson, in his history of the Royal Society, that the hot spring at Bath, has continued at a temperature higher than that of the air for a period of not less than two thousand years, although it is so far distant from any volcano, that, without a very violent and improbable extension of the agency of volcanic fires, it can not be ascribed to them. There are various decompositions of mineral bodies, which generate considerable heat; or, to speak more properly, water is itself the decomposed substance generating heat by its decomposition. The evolution of azotic gas is a proof that the heat of the Bath waters is owing to a particular decomposition which takes place within the bowels of the earth. The greatest heat of these waters is one hundred and sixteen degrees of Fahrenheit's scale; but that of the mineral waters of Carlsbad, in Bohemia, ascends to one hundred and sixty-five degrees.

There are several curious springs which are worthy of notice in this connection, though somewhat varying from the class thus far mentioned. One of these was recently discovered in California, about fifty miles east of San Felipe, in San Diego county. It was discovered by a party engaged in surveying the public lands, and consists of a collection of fountains or springs of soda water, situated in a sandy plain or depression of the surface of the desert. The spring is in a mound of symmetrical shape, tapering like a sugar-loaf, in the center of the top of which is a hole, apparently unfathomable, containing the carbonated beverage fresh from some natural laboratory below. Some of these mounds are six feet high, and clothed with a green and luxuriant coat of grass, while others are shaped like an inverted bowl, and fringed by a growth of cane. The water is described as having the same sparkling and effervescing quality as that ordinarily sold by apothecaries, and was drunk with avidity by both the men and animals belonging to the party discovering it. When impregnated with acid of any kind, it produced instant effervescence, and in that form was peculiarly refreshing as a drink.

Another singular spring has also been discovered on the way from the Great Salt lake, to Los Angelos, through the Cajon pass. The traveler who gives the account of it says: "We had crossed the great desert without any accident, and then camped on a stream of deliciously cool water, about twelve to eighteen inches wide, which distributes itself about half a mile lower down in a meadow covered with luxuriant grasses. This camp-ground is called by the Spaniards, 'Las Vegas.' Once more we had plenty of grass for our fatigued animals, and we determined to rest here for the day. During our journey we passed a number of deserted wagons, chairs, &c. An ox-train from Little Salt lake had preceded about ten days; and it was not difficult to follow their trail, for in the space of one hour I counted the putrid carcasses of nineteen oxen and horses. What a lesson to those who venture on such a journey unadvisedly and unprepared! The strong north wind which blew all day, raised a cloud of dust which almost blinded me,

although I had goggles and a green vail to protect my eyes; however, the delightful and refreshing water of this oasis soon purified me; and I felt, having crossed the desert, breakfasted and bathed, much more comfortable, both mentally and physically. The acacia was the only tree on this stream. Having remained at this camp all one day, the next morning we were on the road to Cottonwood springs, some twenty miles distant, where we would find water and grass, and then commence a journey over another desert of fifty-five miles. We followed up this little stream for about three miles, when the road turned a little to the right; but I was anxious to see the head of the stream, for, from the appearance of the surrounding country, I judged it to be very near. Several gentlemen and myself continued up the stream, and after a ride of half a mile, we came to a large spring, thirty-five feet wide and forty long, surrounded by acacias in full bloom. We approached through an opening, and found it to contain the clearest and most delicious water I ever tasted; the bottom appeared to be not more than two feet from the surface, and to consist of white sand. One of the party prepared himself for a bath, and soon his body divided the crystal waters. While I was considering whether I should go in, I heard him calling to me that it was impossible to sink, the water was so buoyant. I hardly believed it, and, to be able to speak certainly, I also undressed and jumped in. What was my delight and astonishment to find that all my efforts to sink were futile. I raised my body out of the water, and suddenly lowered myself, but I bounded upward as if I had struck a springing-board; I walked about the water up to my armpits, just the same as if I had been walking on dry land. The water instead of being about two feet deep, was over fifteen, the length of the longest tent-pole we had along. It is impossible for a man to sink over his head in it; the sand on the banks is very fine and white; the temperature is seventy-eight degrees of Fahrenheit. I can form no idea as to the cause of this singular phenomenon. Great Salt lake also possesses this quality, but this water is perfectly sweet. In the absence of any other name I have called it Buoyant spring. I have never heard of it as possessing this quality, and should like some of the savants to explain the cause of buoyancy. We lingered in the spring for fifteen minutes, when we dressed and resumed our ride, highly delighted and gratified by our exploration. I made drawings of this spot and surrounding mountains."

Still another singular spring, also in California, was discovered by a Mr. Dabney, when boring for water in San Jose. The auger penetrated through a stiff bed of clay fifty-eight feet thick, when a stream of water was struck which forced itself up the aperture with unprecedented power, and in a volume greater, it is believed, than all the other artesian streams in the neighborhood combined. From this well alone flowed a sufficiency of water to turn a mill. It boiled up with great force, and ran off in a stream four feet wide and six inches deep. At the mouth the current washed out a hole of several feet wide and very deep. Serious apprehensions were entertained, when the stream first burst forth, that it would be impossible to control it. The water was cold and delightful, and it was estimated that the spring would be sufficient to supply the whole city plentifully.

Reciprocating fountains, or springs, may be cited among the most curious phenomena of nature. An irregularity of flow is not uncommon in boiling springs; but there are other springs which evince a periodical influx and reflux, almost as regular as the tides of the ocean. These changes, it will be seen, frequently occur several times in a day, or even in an hour. They are ascribed to various causes, either subterraneous or superficial; but in general, springs and lakes of this description, have been ascertained to communicate with others beneath, through pores or apertures of various diameters, which serve equally to carry off the waters, and to supply them afresh. In such cases the flux and reflux of the upper head of water, must necessarily depend on the state of that beneath; and the causes which alternately augment and diminish the latter, must produce a similar effect on the former.

Paderborn spring, in Westphalia, disappears twice in twenty-four hours, returning constantly, after a lapse of six hours, with a great noise, and so forcibly as to drive three mills at a short distance from its source. The inhabitants call it the _bolderborn_, that is, the boisterous spring. Lay-well spring, near Torbay, is about six feet in length, five in breadth, and nearly six inches deep. The flux and reflux, which are very visible, are performed in about two minutes; when the spring remains at its lowest ebb for the space of about three minutes. In this way it ebbs and flows twenty times within the hour. As soon as the water begins to rise, many bubbles ascend from the bottom; but on its falling, the bubbling instantly ceases. Giggleswick spring, in the West Riding of Yorkshire, lies at the foot of a hill of limestone, named Giggleswick Scar. Its reciprocations are irregular, both with respect to duration and magnitude, the interval of time between any two succeeding flows being sometimes greater, and at other times less, insomuch that a just standard of comparison can not be formed. The rise of the water, in the stone trough or cistern which receives it, during the time of the well's flowing, is equally uncertain, varying from one inch to nine or ten inches, in the course of a few reciprocations. This spring, like the preceding one, discharges bubbles of air at the time of its flowing. Near the lake of Bourget, in Savoy, is a reciprocating spring which rises and falls with a great noise, but not at stated and regular times. After Easter, its ebbings and flowings are frequently perceived six times in an hour; but in dry seasons not more than once or twice. It issues from a rock, and is called =La Fontaine de Merville=, the marvelous fountain.

BITUMINOUS AND OTHER LAKES.

PITCH LAKE OF TRINIDAD.

Near Point la Braye, (Tar point,) the name assigned to it on account of its characteristic feature, in the island of Trinidad, is a lake which at the first view appears to be an expanse of still water, but which, on a nearer approach, is found to be an extensive plain of mineral pitch, with frequent crevices and chasms filled with water. On its being visited in the autumnal season, the singularity of the scene was so great, that it required some time for the spectators to recover themselves from their surprise, so as to examine it minutely. The surface of the lake was of an ash color, and not polished or smooth, so as to be slippery, but of such a consistence as to bear any weight. It was not adhesive, although it received in part the impression of the foot, and could be trodden without any tremulous motion, several head of cattle browsing on it in perfect security. In the summer season, however, the surface is much more yielding, and in a state approaching to fluidity, as is evidenced by pieces of wood and other substances, thrown upon it, having been found enveloped in it. Even large branches of trees, which were a foot above the level, had, in some way, become enveloped in the bituminous matter. The interstices, or chasms, are very numerous, ramifying and joining in every direction; and being filled with water in the wet season, present the only obstacle to walking over the surface. These cavities are in general deep in proportion to their width, and many of them unfathomable: the water they contain is uncontaminated by the pitch, and is the abode of a variety of fishes. The arrangement of the chasms is very singular, the sides invariably shelving from the surface, so as nearly to meet at the bottom, and then bulging out toward each other with a considerable degree of convexity. Several of them have been known to close up entirely, without leaving any mark or seam.

The pitch lake of Trinidad contains many islets covered with grass and shrubs, which are the haunts of birds of the most exquisite plumage. Its precise extent can not, any more than its depth, be readily ascertained, the line between it and the neighboring soil not being well defined; but its main body may be estimated at three miles in circumference. It is bounded on the north and west sides by the sea, on the south by a rocky eminence, and on the east by the usual argillaceous soil of the country.

MUD LAKE OF JAVA.

The following details relative to the volcanic springs of boiling mud in Java are extracted from the Penang Gazette.

Having received an account of a wonderful phenomenon in the plains of Grobogna, a party set off, from Solo, in September, 1814, to examine it. On approaching the place, they saw what at first appeared like the surf breaking over the rocks, with a heavy spray falling to the leeward. Alighting, they went to the “Bluddugs,” as the Javanese call them, which they found to be an elevated plain of mud, about two miles in circumference, in the center of which immense bodies of soft mud were thrown up to the hight of ten or fifteen feet, in the form of large bubbles, which bursting, emitted great volumes of dense white smoke. The largest bubbles, of which there were two, rose and burst some seven or eight times a minute, throwing up from one to three tuns of mud, the smell of the smoke from which was very offensive, like the washings of a gun-barrel. It was both difficult and dangerous to go near the large bubbles, as the surface, except where it had been hardened by the sun, was all a quagmire. They went, however, close to a small bubble, (the plain was full of them, of all sizes,) and observed it for some time. It appeared to heave and swell, and when the air within had raised it to some hight, it burst, and the mud fell down in concentric circles, and then remained quiet till again it was raised, again to burst; which was at intervals of from one to two minutes. The water drained from the mud was collected by the Javanese, and being exposed to the sun deposited crystals of salt.

Next morning the party rode to a place in the forest, to view a salt lake, a mud hillock, and various boiling pools. The lake was about half a mile in circumference, of dirty-looking water, boiling up all over in gurgling eddies; the water being cold, bitter and salt, with an offensive smell. The mud hillock, which was near, was about fifteen feet high, in the form of a cone, with a base of eighty, and a top of eight feet diameter. The top was open, and the interior, which was full of boiling and heaving mud, was found to be eleven fathoms deep. Every rise of the mud was attended by a rumbling noise from within; and the mud was more liquid than at the bluddugs, and unattended by smoke. Near the foot of this hillock was a small pool of water, like that of the lake, boiling violently; and some two hundred yards distant, two larger pools or springs of the same general description, the smell of which was very offensive, and the boiling of which could be heard at quite a distance, resembling the noise of a small waterfall. The water both of the bluddugs and of the lake, is used medicinally by the Javanese, and also, as stated above, for the making of salt, which is gathered in considerable quantities, and the government income from which adds not a little to the public revenues. The general cause of the phenomena here witnessed, is supposed, beyond all question, to be volcanic; the salt water being thrown up by this agency in a heated state, and thus mingling with the soil to produce the boiling and heaving mud above described.

SALT LAKE OF UTAH.

Before leaving the subject of lakes, springs, &c., we must not omit to mention the Great Salt lake of Utah territory, which has been gazed upon with interest by many an emigrant, passing with his family, as represented in the following cut, to his far western home. This lake lies in a region abounding with scenery of unrivaled magnificence and beauty. “Descend from the mountains,” says a late writer, “where you have the scenery and climate of Switzerland, to seek the sky of your choice among the many climates of Italy, and you may find, welling out of the same hills, the freezing springs of Mexico, and the hot springs of Iceland, both together coursing their way to the great salt sea in the plain below. The pages of Malte Brun provide me with a less truthful parallel to it, than those which describe the happy valley of Rasselas, or the continent of Balnibarbi. In the midst of this interesting region, the most remarkable object is the Great Salt lake: which, in the saltness of its waters, in the circumstance of its having no outlet, and being fed from another and smaller lake of fresh water, (with which it is connected by a stream which has appropriately been called the Jordan,) and in the rugged character of some portions of the surrounding region, bears a remarkable resemblance to the Dead sea of Palestine. Instead, however, of lying one thousand feet below, it is more than four thousand feet above the level of the sea; and its waters, being an almost pure solution of common salt, are free from the pungent and nauseous taste which characterizes those of the Dead sea. This lake is about seventy miles long, and thirty miles wide, and is so intensely salt that no living thing can exist in it; and by evaporation in hot weather, it leaves on its shores a thick incrustation of salt.

[Illustration: THE EMIGRANT FAMILY.]

Some twenty-five miles south of this, and connected with it by the river Jordan, as mentioned above, is Utah lake, a body of fresh water, some thirty-five miles in length, which abounds with trout and other fish. And some seven hundred feet higher still, is Pyramid lake, on the slope of the Sierra Nevada mountains, so named from a singular pyramidal mount rising from its transparent waters to the hight of some six hundred feet; and walled in by almost perpendicular precipices, in some places three thousand feet high. Some distance from here, too, are the _boiling springs_, described by Fremont, the largest basin of which is several hundred feet in circumference, and has a circular space at one end some fifteen feet in diameter, entirely occupied with the boiling water. A pole sixteen feet in length, was entirely submerged on thrusting it down near the center; and the temperature of the water near the edge was two hundred and six degrees. In this vicinity also, are appearances similar to the _mirages_ of the great deserts of the old world. In traveling over the salt deserts of the Fremont basin, his party saw themselves reflected in the air, probably, as Fremont himself suggests, from the saline particles floating in the atmosphere, and in some way affecting its refracting power. The entire region, is one of great wildness and grandeur.

ATMOSPHERICAL PHENOMENA.

METEORS.

From look to look, contagious through the crowd The panic runs, and into wond’rous shapes The appearance throws: armies in meet array, Thronged with aerial spears and steeds of fire; Till the long lines of full-extended war In bleeding fight commixt, the sanguine flood Rolls a broad slaughter o’er the plains of heaven. As thus they scan the visionary scene, On all sides swells the superstitious din. Incontinent; and busy frenzy talks Of blood and battle; cities overturned, And late at night in swallowing earthquake sunk, Or hideous wrapt in fierce ascending flame; Of sallow famine, inundation, storm; Of pestilence, and every great distress; Empires subversed, when ruling fate has struck The unalterable hour: even nature’s self Is deemed to totter on the brink of time. Not so the man of philosophic eye, And aspect sage; the waving brightness he Curious surveys, inquisitive to know The causes, and materials, yet unfixed, Of this appearance beautiful and new.—THOMSON.

The nature of those splendid phenomena of the heavens which are embraced under the general term meteors, can not be so well elucidated as by an extract from the travels of Messrs. Humboldt and Bonpland to the equinoctial regions of the new continent. The sublime wonders described by the former of these travelers were witnessed by them at Cumana, a city of Venezuela, in South America.

“The night of the eleventh of November, 1779, was cool and extremely beautiful. Toward the morning, from half after two, the most extraordinary luminous meteors were seen toward the east. M. Bonpland, who had risen to enjoy the freshness of the air in the gallery, perceived them first. Thousands of bolides (fire-balls) and falling stars, succeeded each other during four hours. Their direction was very regular, from north to south. They filled a space in the sky extending from the true east thirty degrees toward the north and south. In an amplitude of sixty degrees the meteors were seen to rise above the horizon at east-north-east, and at east to describe arcs more or less extended, falling toward the south, after having followed the direction of the meridian. Some of them attained a hight of forty degrees; and all exceeded twenty-five or thirty degrees. There was very little wind in the low regions of the atmosphere, and this blew from the east. No trace of clouds was to be seen. M. Bonpland relates, that from the beginning of the phenomenon, there was not a space in the firmament equal in extent to three diameters of the moon which was not filled at every instant with bolides and falling stars. The first were fewer in number, but as they were seen of different sizes, it was impossible to fix the limit between these two classes of phenomena. All these meteors left luminous traces from five to ten degrees in length, as often happens in the equinoctial regions. The phosphorescence of these traces, or luminous bands, lasted seven or eight seconds. Many of the falling stars had a very distinct nucleus, as large as the disk of Jupiter, from which darted sparks of vivid light. The bolides seemed to burst as by explosion; but the largest, those from one degree to one degree and fifteen minutes in diameter, disappeared without scintillation, leaving behind them phosphorescent bands (_trabes_) exceeding in breadth fifteen or twenty minutes, or sixtieth parts of a degree. The light of these meteors was white, and not reddish, which must be attributed, no doubt, to the absence of vapors, and the extreme transparency of the air. For the same reason, under the tropics, the stars of the first magnitude have, at their rising, a light evidently whiter than in Europe.

“Almost all the inhabitants of Cumana were witnesses of this phenomenon, and did not behold these bolides with indifference; the oldest among them remembered, that the great earthquakes of 1766 were preceded by similar phenomena. The fishermen in the suburbs asserted, that the fire-work had begun at one o’clock; and that, as they returned from fishing in the gulf, they had already perceived very small falling stars toward the east. They affirmed at the same time, that igneous meteors were extremely rare on those coasts after two in the morning.

“The phenomenon ceased by degrees after four o’clock, and the bolides and falling stars became less frequent; but we still distinguished some toward the north-east, by their whitish light, and the rapidity of their movement, a quarter of an hour after sunrise. This circumstance will appear less extraordinary, when I state that in full daylight, in 1788, the interior of the houses in the town of Popayan was highly illumined by an aerolite of immense magnitude. It passed over the town when the sun was shining clearly, about one o’clock. M. Bonpland and myself, during our second residence at Cumana, after having observed on the twenty-sixth of September, 1800, the immersion of the first satellite of Jupiter, succeeded in seeing the planet distinctly with the naked eye, eighteen minutes after the disk of the sun had appeared in the horizon. There was a very slight vapor in the east, but Jupiter appeared on an azure sky. These facts prove the extreme purity and transparency of the atmosphere under the torrid zone. The _mass_ of diffused light is so much less, as the vapors are more perfectly dissolved. The same cause that weakens the diffusion of the solar light, diminishes the extinction of that which emanates either from a bolis, Jupiter, or the moon, seen on the second day after her conjunction.

“The researches of M. Chladni having singularly fixed the attention of the scientific world upon the bolides and falling stars, at my departure from Europe, we did not neglect during the course of our journey from Caraccas to the Rio Negro, to inquire everywhere, whether the meteors of the twelfth of November had been perceived. In the savage country, where the greater number of the inhabitants sleep out in the air, so extraordinary a phenomenon could not fail to be remarked, except when concealed by clouds from the eye of observation. The Capuchin missionary at San Fernando de Apura, a village situated amid the savannas of the province of Varinas, and the Franciscan monks stationed near the cataracts of the Orinoco, and at Maroa, on the banks of the Rio Negro, had seen numberless falling stars and bolides illumine the vault of heaven. Maroa is south-west of Cumana, and one hundred and seventy-four leagues’ distance. All these observers compared the phenomenon to a beautiful fire-work, which had lasted from three till six in the morning. Some of the monks had marked the day upon their ritual; others had noted it by the nearest festivals of the church. Unfortunately, none of them could recollect the direction of the meteors, or their apparent hight. From the position of the mountains and thick forest which surround the missions of the cataracts and the little village of Maroa, I presume that the bolides were still visible at twenty degrees above the horizon. On my arrival at the southern extremity of Spanish Guiana, at the little fort of San Carlos, I found a party of Portuguese, who had gone up the Rio Negro from the mission of St. Joseph of the Maravitains, and who assured me, that in that part of Brazil, the phenomenon had been perceived, at least as far as San Gabriel das Cachoeiras, consequently as far as the equator itself.

“I was powerfully struck at the immense hight which these bolides must have attained, to have been visible at the same time at Cumana, and on the frontiers of Brazil, in a line of two hundred and thirty leagues in length. But what was my astonishment, when at my return to Europe, I learned that the same phenomenon had been perceived, on an extent of the globe of sixty-four degrees of latitude, and ninety-one degrees of longitude; at the equator, in South America, at Labrador, and in Germany! I found accidentally, during my passage from Philadelphia to Bordeaux, in the memoirs of the Pennsylvanian society, the corresponding observations of Mr. Ellicott (latitude thirty degrees, forty-two minutes;) and, upon my return from Naples to Berlin, I read the account of the Moravian missionaries among the Esquimaux, in the library of Göttingen. Several philosophers had already discussed at this period the coincidence of the observation in the north with those at Cumana, which M. Bonpland and I had published in 1800.

“The following is a succinct enumeration of facts. First, the fiery meteors were seen in the east, and the east-north-east, to forty degrees of elevation, from two to six hours at Cumana, (latitude ten degrees, twenty-seven minutes, fifty-two seconds, longitude sixty-six degrees, thirty minutes;) at Porto Cabello, (latitude ten degrees, six minutes, fifty-two seconds, longitude sixty-seven degrees, five minutes;) and on the frontiers of Brazil, near the equator, in the longitude of seventy degrees west of the meridian of Paris. Secondly, in French Guiana, (latitude four degrees, fifty-six minutes, longitude fifty-four degrees, thirty-five minutes,) the northern part of the sky was seen all on fire. Innumerable falling stars traversed the heavens during an hour and a half, and diffused so vivid a light, that those meteors might be compared to the blazing sheaves shot out from fire-works. Thirdly, Mr. Ellicott, an astronomer in the United States, having terminated his trigonometric operations for the rectification of the limits on the Ohio, being, on the twelfth of November, in the gulf of Florida, in the latitude of twenty-five degrees, and longitude eighty-one degrees, fifty minutes, saw, in all parts of the sky, ‘as many meteors as stars, moving in all directions: some appeared to fall perpendicularly; and it was expected every minute that they would drop into the vessel.’ The same phenomenon was perceived upon the American continent as far as the latitude of thirty degrees, forty-two minutes. Fourthly, in Labrador, at Nain (latitude fifty-six degrees, fifty-five minutes) and Hoffenthal (latitude fifty-eight degrees, four minutes,) and in Greenland, at Lichtenau (latitude sixty-one degrees, five minutes) and New Herrnhutt, (latitude sixty-four degrees, fourteen minutes, longitude fifty-two degrees, twenty minutes,) the Esquimaux were frightened at the enormous quantity of bolides which fell during twilight toward all points of the firmament, some of them being a foot broad. Fifthly, in Germany, M. Zeissing, vicar of Itterstadt, near Weimar, (latitude fifty degrees, fifty-nine minutes, longitude nine degrees, one minute east,) perceived, on the twelfth of November, between the hours of six and seven in the morning, when it was half after two at Cumana, some falling stars, which shed a very white light. Soon after, toward the south and south-west, luminous rays appeared from four to six feet long: they were reddish, and resembled the luminous track of a sky-rocket. During the morning twilight, between the hours of seven and eight, the south-west part of the sky was seen, from time to time, strongly illuminated by white lightning, which ran in serpentine lines along the horizon. At night the cold increased, and the barometer rose.

“The distance from Weimar to the Rio Negro, is eighteen hundred sea leagues; and from Rio Negro to Herrnhutt, in Greenland, thirteen hundred leagues. Admitting that the same fiery meteors were seen at points so distant from each other, we must also admit, that their hight was at least four hundred and eleven leagues. Near Weimar, the appearance like sky-rockets was seen in the south and south-east; at Cumana, in the east and in the east-north-east. We may therefore conclude, that numberless aerolites must have fallen into the sea, between Africa and South America, to the west of the Cape Verde islands. But, since the direction of the bolides was not the same at Labrador and at Cumana, why were they not perceived in the latter place toward the north, as at Cayenne? I am inclined to think, that the Chayma Indians of Cumana did not see the same bolides as the Portuguese in Brazil, and the missionaries in Labrador; but, at the same time, it can not be doubted, and this fact appears to me very remarkable, that in the new world, between the meridians of forty-six degrees and eighty-two degrees, between the equator and sixty-four degrees north, at the same hour, an immense number of bolides and falling stars were perceived; and that those meteors had everywhere the same brilliancy, throughout a space of nine hundred and twenty-one thousand square leagues.

“The scientific men who have lately made such laborious researches on falling stars and their parallaxes, consider them as meteors belonging to the furthest limits of our atmosphere, between the region of the =aurora borealis= and that of the lightest clouds. Some have been seen, which had not more than fourteen thousand toises, or about five leagues of elevation. The highest do not appear to exceed thirty leagues. They are often more than a hundred feet in diameter; and their swiftness is such, that they dart, in a few seconds, over a space of two leagues. Some of these have been measured, the direction of which was almost perpendicularly upward, or forming an angle of fifty degrees with the vertical line. This extremely remarkable circumstance has led to the conclusion, that falling stars are aerolites, which, after having hovered about a long time in space, take fire on entering accidentally into our atmosphere, and fall toward the earth.

“Whatever may be the origin of these luminous meteors, it is difficult to conceive any instantaneous inflammation taking place in a region where there is less air than in the vacuum of our air-pumps; and where (twenty-five thousand toises high) the mercury in the barometer would not rise to twelve-thousandths of a line. We have ascertained the uniform mixture of atmospheric air to three-thousandths nearly, only to an elevation of three thousand toises: consequently, not beyond the last stratum of fleecy clouds. It might be admitted, that, in the first revolutions of the globe, gaseous substances which yet remain unknown to us, may have risen toward that region, through which the falling stars pass: but accurate experiments, made upon mixtures of gases which have not the same specific gravity, prove that we can not admit a superior stratum of the atmosphere entirely different from the inferior strata. Gaseous substances mix and penetrate each other with the least motion; and a uniformity of their mixture would have taken place in the lapse of ages, unless we suppose in them the effects of a repulsive action unexampled in those substances which we can subject to our observations. Further, if we admit the existence of a particular aerial fluid in the inaccessible region of luminous meteors, falling stars, bolides, and the =aurora borealis=, how can we conceive why the whole stratum of those fluids does not at once take fire, but that the gaseous emanations, like the clouds, occupy only limited spaces? How can we suppose an electrical explosion without some vapors collected together, capable of containing unequal charges of electricity, in air, the mean temperature of which is, perhaps, twenty-five degrees below the freezing-point of the centigrade thermometer, and the rarefaction of which is so considerable, that the compression of the electrical shock could scarcely disengage any heat? These difficulties would in great part, be removed, if the direction of the motion of falling stars allowed us to consider them as bodies with a solid nucleus, as cosmic phenomena (belonging to space beyond the limits of our atmosphere) and not as telluric phenomena (belonging to our planet only.)

“Supposing that the meteors of Cumana were only at the usual hight at which falling stars in general move, the same meteors were seen above the horizon in places more than three hundred and ten leagues distant from each other. Now, what an extraordinary disposition to incandescence must have reigned on the twelfth of November, in the higher regions of the atmosphere, to have furnished, during four hours, myriads of bolides and falling stars, visible at the equator, in Greenland, and in Germany.

“Mr. Benzenberg judiciously observes, that the same cause, which renders the phenomenon more frequent, has also an influence on the largeness of the meteors, and the intensity of their light. In Europe, the nights when there are the greatest number of falling stars, are those in which very bright ones are mixed with very small ones. The periodicalness of the phenomenon augments the interest which it excites. There are months, in which M. Brandes has reckoned in our temperate zone, only sixty or eighty falling stars in one night; and in other months their number has risen to two thousand. Whenever one is observed, which has the diameter of Sirius or of Jupiter, we are sure of seeing so brilliant a meteor succeeded by a great number of smaller meteors. If the falling stars be very frequent during one night, it is very probable that this frequency will continue during several weeks. It would seem that, in the higher regions of the atmosphere, near that extreme limit where the centrifugal force is balanced by gravity, there exists, at regular periods, a particular disposition for the production of bolides, falling stars, and the =aurora borealis=. Does the periodicalness of this great phenomenon depend upon the state of the atmosphere? or upon something which the atmosphere receives from without, while the earth advances in the ecliptic? Of all this we are still as ignorant as men were in the days of Anaxagoras.

“With respect to the falling stars themselves, it appears to me, from my own experience, that they are more frequent in the equinoctial regions than in the temperate zone; more frequent over the continents, and near certain coasts, than in the middle of the ocean. Do the radiation of the surface of the globe, and the electrical charge of the lower regions of the atmosphere, which varies according to the nature of the soil, and the positions of the continents and seas, exert their influence as far as those hights, where eternal winter reigns? The total absence even of the smallest clouds, at certain seasons, or above some barren plains destitute of vegetation, seems to prove, that this influence can be felt at least as far as five or six thousand toises high. A phenomenon analogous to that of the twelfth of November, was observed thirty years before, on the table-land of the Andes, in a country studded with volcanoes. At the city of Quito, there was seen, in one part of the sky, above the volcano of Gayambo, so great a number of falling stars, that the mountain was thought to be in flames. This singular sight lasted more than an hour. The people assembled in the plain of Exico, where a magnificent view presents itself of the highest summit of the Cordilleras. A procession was already on the point of setting out from the convent of St. Francis, when it was perceived that the blaze of the horizon was caused by fiery meteors, which ran along the skies in all directions, at the altitude of twelve or thirteen degrees.”

The bolides, or fire-balls, and falling stars, so striking an example of which is given above, are of all sizes, from a small shooting-star of the fifth magnitude, to a cone or cylinder of two or three miles in diameter. They differ in consistency as much as in dimensions, and in color as much as in either. Occasionally, they are a subtile, luminous and pellucid vapor; and sometimes a

compact ball, or globe, as though the materials of which they are formed, were more condensed and concentrated. Not unfrequently they have been found to consist of both, and consequently to assume a comet-like appearance, with a nucleus or compact substance in the center, or toward the center, and a long, thin, pellucid or luminous main, or tail, sweeping on each side. They are sometimes of a pale white light; at others, of a deep igneous crimson; and, occasionally iridescent and vibratory. The rarer meteors appear frequently to vanish on a sudden, as though abruptly dissolved or extinguished in the atmospheric medium, their flight being accompanied by a hissing sound, and their disappearance by an explosion. The most compact of them, or the nuclei of those which are rarer, have often descended to the surface of the earth, and with a force sufficient to bury them many feet under the soil; generally exhibiting marks of imperfect fusion and considerable heat. The substance is, in these cases, for the greater part metallic; but the ore of which they consist is not anywhere to be found, in the same constituent proportions, in the bowels of the earth. Under this form the projected masses are denominated aerolites, or meteoric stones.

It may not be uninteresting to preface a succinct account of the most surprising of these meteors, by a notice of the hypotheses which have been imagined concerning them; however justly the learned Humboldt may have concluded, in the words of the extracts given above, that we are still “as ignorant on this subject as men were in the days of Anaxagoras.” Sir J. Pringle contended, with other philo

Chapter II. Curative Value of X-Rays—X-Rays Cure Whooping Cough—X-Rays for Malaria 18

Chapter III. Martyrs to Radiology 32

Chapter IV. Discovery and Nature of X-Rays 43

Chapter V. Ultra-Violet Light in Health and Disease—Sunlight and Infantile Paralysis 48

INTRODUCTION

Highly important as are the phenomena of Radioactivity from the physical, chemical, medical, and philosophic points of view, they are hardly comparable in their relations to the affairs of our everyday life to the Roentgen or X-rays, and to the invisible violet or ultra-violet rays. The X-rays are utilized today in hundreds of practical ways, and are vastly important also in surgery, medicine, dentistry, and in biological investigations. It is perhaps not too much to say that the discovery of the so-called X-rays should be numbered among the two or three most important revelations of modern science. This will be clearly demonstrated in the course of the chapters to follow.

X-RAY, VIOLET RAY AND OTHER RAYS

CHAPTER I

EVERYDAY USES OF X-RAYS

To enumerate and describe all the practical uses of X-rays, apart from medicine and scientific research in general, would require a good many more pages than can be devoted to the subject here. To take a few cases at random, without describing the instruments and methods employed: radiography reveals flaws in the structure of iron and steel building and bridge materials, and in the cylinders of airplane engines, and so avoids accidents. In England a gasoline or petrol tank was shown to have rivet heads

on the outside and none on the inside.

Serious defects in the steel axles of railway and automobile “under carriages” have been discovered by radiography. In one case, at least, the axles had been drilled in the wrong position and the holes had been simply filled with metal and covered over. An entire lot was rejected in consequence and probably serious accidents were forestalled.

“Cracks in castings, bad welds and weak places which do not show on the surface of metal are perfectly clear to the searching rays. How much would you give to _know_ that that welded part in your automobile is really solid and perfect, that it contains no flaw to break down some day when you are twenty miles from a machine shop? A well-known mechanical engineer said recently that in ten years a metallurgical X-ray machine will be as vital a part of the equipment in an automobile repair shop, a foundry, or machine shop as it is now in a dentist’s office.”

We are assured by _The Iron Trade_ (73:26) that “the practice of analyzing metals by means of X-rays is only in its infancy. There is every reason to believe that soon great advances will be made in determining the crystallization and therefore the properties of metals. Students of metallurgy are well aware that the properties of metals and other bodies depend on the nature of their crystallization. The microscope has rendered valuable service largely because it enables the form and arrangement of the crystalline grains to be studied. The X-ray carries the same form of inquiry into a region 10,000 times more minute, thereby furnishing new evidence as to crystalline structures, so that it is now possible to see the atoms and the molecules, and the way they form crystals. Every crystal has its characteristic X-ray spectrum and can be identified thereby even when the individual crystals are beyond the resolving power of the microscope and the substance is in danger of being called amorphous. If a specimen contains a mixture of crystalline substances, the spectrum shows the combined effect of all the substances, and provided each individual spectrum is known, the specimen can be analyzed.”

The X-rays are also used to determine the quality of the fabric in automobile tires, and even to detect irregularities in the centers of golf balls, and to reveal why some of them fly straighter and farther than others.

“The professional detective, too,” says Mr. Wilfred S. Ogden (_Popular Science Monthly_, August, 1923), “will find X-rays useful in his business. Consider the detection of infernal machines, for example. Two or three X-ray plates will tell an investigator just what is in a suspicious-looking box. If it is a bomb the X-ray will show him how to get it apart and render it harmless. Immediate detection of false bottoms in trunks is child’s play with the X-ray. When the government provided its customs inspectors with X-ray machines the gems which smugglers try to hide in the linings of clothes or in hollow-handled hairbrushes might as well be worn openly.

“The X-rays give us one of the easiest ways to detect the alteration of checks and other documents. It is seldom that such an alteration is made with exactly the same ink used on the original. Inks even of the same color, differ in the way they affect the rays. In most cases all that is necessary to detect an alteration is to place the suspected document for a moment under the X-rays and make a photograph of it. The new ink used in the alteration will stand out clearly as different from the old.

“The industrial detective will find X-rays just as useful. The adulteration of foods by sawdust, sand or clay; the adding of too much filler to paper; the presence of grit in lubricating oil, all will be revealed.

“Another use of the rays comes home to every cook and housewife. X-rays constitute the only sure way to tell good eggs from bad. Pass each egg in turn through the X-rays and let its shadow fall on a chemical screen. You will see exactly what is inside each egg. The ones containing hopeful chicks may be rejected.”

One of the most remarkable economic or biological uses of the X-ray so far developed is the study of silk-worms and their diseases. The Silk Association of America has established a laboratory—Department of Sericulture—in the Canton Christian College, presided over by a staff of Chinese and foreign entomologists. Here the silk-worm is X-rayed by powerful microscopes, and all his disorders diagnosed and corrected, says Mr. Philip A. Yountz (_Scientific American_, September, 1925).

“Numerous autopsies on deceased members of the silk-worm tribe revealed that from 50 to 100 percent of the worms raised in South China were infected with diseases that made the infant mortality rate excessively high and destroyed the value of the silk from those hardy enough to survive. The elimination of these diseases would enable South China to produce four or five times as much silk.”

In Great Britain, X-rays are used in the analysis of coal, the method being an adaptation of the X-ray stereoscope.

In Berlin, S. Nalken, a noted criminologist, has devised an important improvement in finger-print identification. X-ray pictures are obtained of the finger, with the muscles and bones. This is done without the use of any chemicals that could obstruct the delicate furrows of the finger lines. Moreover, the finger bone is shaped so characteristically as to aid identification. Whenever a certain likeness of finger-lines is discovered, the bones are examined to see if further research is necessary.

Picture fakers have been dethroned by application of the X-ray to paintings. Recently painted “old masters” are now easily detected. Modern artists use white-lead, which is more opaque than the “priming” or “sizing” used by the older artists; and the X-ray device “made in Germany” in 1914 by Dr. Faber, and further developed by the French expert, Dr. André Chéron, at once distinguishes the old from the new. One picture by Van Ostade, of men drinking at a table, proved to be a fraud when submitted to the X-ray; it had been painted over a study of dead birds. Another, called “The Royal Child,” a supposed 16th century work, now in the Louvre, was proved to have been painted during the 19th century over a picture of very much earlier date.

During a popular lecture on the X-ray in London, before the Royal Institution, the distinguished physicist, Prof. G. W. C. Kaye, showed a number of radiograph slides, among which were two pictures by Dutch painters, one representing the Madonna and the other the Crucifixion. In the former, the Madonna appeared to be looking at something which was non-existent in the canvas, and a radiograph proved the missing object was a child which some former owner of the picture had painted out. In the second picture, a woman in the attitude of prayer was found to have been painted over what was in the original the figure of a man in monk’s garb.

The first X-ray pictures ever taken of a mummy were completed by scientists at the American Museum of Natural History, New York City. The pictures showing the skeleton in detail are expected to be a great aid in studying the development of bone formations in the evolution of man. This first subject of the scientists’ X-ray was a South American Indian mummy. Fake mummies, like false gems, are instantly detected by X-ray methods.

One of the methods used for detecting the theft of diamonds at the mines is to examine the workmen with X-rays. Of course, a fluoroscope is used to make the X-ray image visible, and this is the type used in any regular X-ray work.

The X-rays are now being used in shoe-stores—“foot-o-scope” instruments—to enable shoe salesmen to see the bones of a customer’s foot and thus make correct fittings of shoes.

A few years ago there arrived from Germany a new kind of mechanical doll. “A secret mechanism inside enabled it to walk, sit down or stand up, and to do other unusual things. The importer in possession of the sample doll would not allow it to be opened. But one of the competitors borrowed the doll. He had promised not to open it. But he made some X-ray photographs of it. Now he is manufacturing these dolls himself.”

During the World War every effort was made to introduce contraband materials into Germany and if it had not been for the all-seeing eye of the Roentgen ray, it would have been impossible to prevent materials of the utmost importance to the enemy from reaching him by way of neutral countries. Efforts were made repeatedly to smuggle rubber and copper by burying them in bales or bundles of other materials. It would have been impossible to have made a minute investigation of every bale that was shipped, but by means of X-rays it was possible to see through these bundles and packages and locate any substances that were more or less opaque to the rays.

The X-ray has been found useful for examining timber up to 18 inches thick for internal knots, resin pockets, cracks and other defects.

“When submarines were active and the supply of the best kinds of wood was uncertain, it was necessary to make some of the wooden parts out of small pieces of ordinary wood fitted and glued together. The way these pieces were joined and fastened was extremely important. A bit of weak glue inside some little strut might mean a disastrous collapse in the air. But real inspection seemed impossible, for the places where important faults might exist were hidden from view. Finally scientists solved the problem by building an X-ray apparatus with which they could look into the inside of each built-up airplane part and tell whether it held some little imperfection which might prove dangerous.

“This ‘internal inspection’ of wooden articles by X-ray has been applied, since the war, to many other articles. Hidden joints inside high-class furniture and cabinet work, invisible knots and flaws inside the wood itself, can be determined easily by X-ray examination.” (W. S. Ogden).

The Scientific American (September, 1924) published an abstract of a paper read before the _Deutschen Bunsen-Gesellschaft_, in which Dr. D. Coster showed that “the relations between the X-ray spectra of the different elements are so simple that, in some respects, they are more useful for purposes of chemical analysis than ordinary luminous spectra. An important advantage is the fact that the X-ray spectrum of an element is quite independent of the nature of the compound containing it. It is easy to detect the presence in a mixture of which not more than one milligram is available. Certain precautions are necessary in examining the X-ray spectra; although the number of lines for each element is comparatively limited, recent observations have shown the existence of a number of weaker lines; in addition to this, with the high voltages now generally used, not only the spectrum of the first order, but also those of higher orders appear. Slight impurities in the material of the anticathode, and in the subject under examination, also give their lines, so that there are often various possibilities to be considered before a given line can be explained. Not only the wave length, but also the typical appearance of the suspected lines must be considered, as well as their relative intensity. By measuring photometrically the intensity of the spectral lines it is possible, in some cases, to obtain a quantitative estimate of the amount of an element present in a mixture.”

Another method of rapid analysis of material in the laboratory by the use of X-rays in a much shorter time than that required by the older chemical methods is that devised by Professor Urbain, of the Minero-Chemical Laboratory at the Sorbonne, with the assistance of Eugene Delaunay. Mr. Delaunay, who did the actual work of testing the new X-ray method, says there is no risk of error.

By employment of X-rays the scientist is now able to ascertain the arrangement of the atoms and molecules within the crystal “network” (structure—or “space lattice” of the crystal).[1] The results are obtained from the study of the reflection and refraction of the rays by the crystals, or, more precisely, the successive rows of molecules in the crystal. These act toward the extremely short X-rays in the same way as a grating spectroscope does to ordinary light-rays.

Man’s ability to lengthen the ultra-violet end of the spectrum is limited by his capacity to provide a diffraction grating, or a mineral prism, which can split up light-waves of increasingly greater frequency (or shortness). The width of a grating space (a fine line on speculum metal, which acts as a minute mirror) must be comparable to the wave length of the light. Previous to the discoveries of Prof. Max von Laue in Munich (now in Zurich), and Prof. William Henry Bragg, of the University of London, no grating or other material was known whose spaces were as small as the wave length of X-rays. Laue conceived the brilliant idea that the regular arrangement of the atoms in a crystal might serve the purpose. They did. Bragg, and later his son, Prof. W. L. Bragg, of the University of Manchester, followed up the work of Laue with results of immeasurable value to science.

A very important relation between the atomic number of an element and its X-ray spectrum was discovered by the brilliant young English physicist, H. G. T. Moseley (1888-1915), in his 26th year, a year before his death by a Turkish bullet at the Dardanelles. While analyzing the characteristic X-rays which are given off when any kind of substance is bombarded with cathode rays, Moseley found that the atoms of all the different substances emit radiations or groups of radiations which are extraordinarily similar, but which differ in their wave lengths as we proceed from substance to substance; the frequencies (wave lengths) change by definite steps as one progresses from elements of lower to elements of higher atomic weights. Through Moseley’s epoch-making discovery we now know that each of the 92 elements, from hydrogen to uranium, is built up by successive additions of one positive charge (proton) and one negative electron, and that the atomic numbers—from 1 to 92—correspond to the number of protons and electrons in each successively heavier (and more complex) atom.

FOOTNOTES:

[1] This phase of our subject can only be alluded to in this little book. For an authoritative yet easily understood exposition of the subject, see Bragg, W. H. and W. L., “X-Rays and Crystal Structure”; also Kaye, G. W. C., “X-Rays”; and, for more advanced reading, deBroglie, Maurice, “X-Rays”.

CHAPTER II

CURATIVE VALUE OF X-RAYS

In my Little Blue Book on Radium (No. 1000), it is shown that the “emanation” and the “gamma rays” of radioactive substances are being used to great advantage in our hospitals, but that certain dangers to the patient’s normal cells attended employment of these radiations.

It is gratifying to note that successful X-ray treatments are now being given in cases of cancer, rays being produced—under high-tension currents—that are almost identical with the gamma rays of radium.

Moreover, the X-rays have a double value in medicine. In the first place, they are used as an aid to diagnosis, forming those branches of radiotherapy known as radioscopy and radiography. Then they are also used to great advantage in the alleviation or cure of certain maladies. By means of radioscopic or radiographic examination it may be found that there is a tumor in the chest, and as a result of that diagnosis it may be decided to institute treatment (radiotherapy) by means of X-rays or radium rays or the two combined.

The method of employing extremely penetrating X-rays—under high voltage and amperage—seems to have been first used in Germany, during the World War, but was soon developed to a high degree of efficiency in France, England, and the United States, especially by Dr. William Duane, professor of biophysics at Harvard.

As early as 1919, Professor Dessauer, in Germany, produced the penetrating X-rays by means of a high-tension current ranging from 170,000 to 240,000 volts. It was later found, that rays at 200,000 volts became homogeneous, so that a further increase was considered as of no therapeutic value.

In March, 1923, Dr. I. Seth Hirsch, head of the X-ray department of the Bellevue Hospital in New York, gave a drastic treatment—for cancer—of four periods of 16 hours each with the X-rays at 250,000 volts, apparently with satisfactory results. The patient suffered no pain or inconvenience during the treatment with the exception of occasional nausea. A year later an experiment was made in a Philadelphia laboratory where an X-ray treatment of 300,000 volts was used. It seems that alleviation rather than cure has been the result of nearly all cases where cancer had been well advanced.

Other important improvements, meanwhile, were being introduced by the German specialists, during the World War and later, among which was the just mentioned method of giving large tissue-destroying doses, requiring from ten to 15 hours; to this was added careful filtration of the rays, and the invention of the _ionto_—a quantimeter for exact measurements. A number of malignant diseases is reported to have yielded to this new system of massive doses under higher voltage. But Professor Duane has stated that neither X-rays nor the gamma rays of radium should be considered as a permanent cure for cancer.

Until recently the tubes in which X-rays are produced have always been made of glass. The latest discovery is a tube made of fused silica, or vitreosil. Vitreosil permits the passage of the short rays, will stand a much higher temperature than glass, and is much stronger. This means more continuous service from X-rays.

According to Dr. Francis C. Wood, director of the Crocker Institute of Cancer Research of Columbia University, a marked advance in the treatment of cancer has been made possible by a new type of X-ray tube, the invention of Dr. C. T. Ulrey, of the Westinghouse Company. The new tube has a higher emissive power—in other words, it is as if the candle-power of an ordinary lamp were increased six-fold. It is besides designed for use with higher voltages than have previously been practical in Roentgenology. The result is to reduce the necessary exposure from two or three hours per patient to 20 minutes, and to increase the life of the tubes. Incidentally, the new tube gives a greater proportion of the type of rays that cure certain forms of cancer, and less of the sort that attack healthy tissue.

A revolutionary discovery by Dr. Jacques Forestier, of Aix-les-Bains, France, for which a gold medal was awarded him in 1925 by the French Academy, has made possible a method of exact diagnosis by X-rays heretofore deemed by many workers impossible of attainment.

As is well known, it is not difficult to make an X-ray picture of the bones of the body. They are so much denser than the soft parts of the body that, even with the ordinary photographic plate, it has been possible to photograph them fairly well. By pumping the stomach full of gas or air—which are highly transparent to the X-rays—and then applying the X-ray, it has sometimes been possible to locate the beginnings of cancer of the stomach, and the place of malignant growth.

Another method in common use is to give the patient about a pint of some substance opaque to X-rays, such as bismuth carbonate, thus making it possible to record the passage of the mixture, the outline of the stomach and the intestines thus being made visible. In this way ulcers of the stomach have been frequently located.

Bismuth and similar substances could not be injected into the brain or spinal cord, on account of their poisonous effect on the highly sensitive cells of these regions. Now, thanks to the method discovered by Dr. Forestier, the cavities of the brain and spine can be

safely explored, as well as the network of bronchial tubes in the lung—the so-called “bronchial tree.”

In an interview with Mr. David Dietz, Dr. Forestier said (in part):

“I make use of a French oil called lipiodol. It is a chemical compound composed of poppyseed oil and iodine. The chemical previously had been used as a treatment for certain diseases, such as goiter. But no one had ever thought of using it in X-ray work.

“I noticed that where patients had been treated with lipiodol opaque spots appeared when X-ray pictures were made of the treated parts. It occurred to me, therefore, that lipiodol could be used as a means of making photographs.

“Accordingly, in company with Dr. Sicard of Paris, I began to experiment. We worked with animals until we were convinced of the correctness of our method. When we were sure that it was safe we tried it on human beings. I have used it in more than 5,000 cases in Europe without having a single adverse result.

“The lipiodol is injected into the brain cavity or the canal of the spinal cord or the bronchial tubes and then a regular X-ray photograph is made. The oil renders the injected part opaque to X-rays and they show up as sharp black images in the photographs.

“The method is of particular value when a patient is suffering from paralysis which has been caused by a pressure of a tumor or growth somewhere along the spinal cord. In this case a drop of the oil is injected into the spinal canal at the base of the brain. In a healthy patient it would immediately travel to the base of the spine. But in the paralyzed patient it only travels as far as the point of compression. The X-ray picture therefore reveals the drop of oil as a black spot. The surgeon then knows the exact spot at which to operate in order to find the growth causing the pressure, which in turn results in paralysis.

“In diagnosing the lungs with the use of lipiodol the injection in the bronchial tree enables the X-ray worker to tell at once whether the patient is suffering from diseases of the bronchial tubes themselves, or from diseases of the lung tissue, such as tuberculosis.”

It is gratifying to be able to relate that along with the improvements already described, progress has also been made in the preparation of photographic plates required by the radiographer. Until recently no photographic plate had been made which fully met the requirements of X-ray work, and there was little contrast in X-ray photographs. They were all much too sensitive to the longer (visible) wave lengths, and produced blurring effects.

Early in 1921 an excellent photographic plate, 25 times more rapid than anything previously known, was invented by Dr. Leonard A. Levey, a prominent member of the Roentgen Society. It makes an X-ray photograph of the vital organs of the living body whose movements have hitherto blurred the images on the ordinary photographic plate. Distinct pictures of the heart, lungs and stomach can now be made. Dr. Levey has made snapshot photographs of the heart, lungs and kidneys. All were taken in a flash with the X-rays on the new plate.

Dr. H. Becher has called the attention of Americans to the achievement of Dr. Schleussner, an eminent German authority in photochemical matters, who has succeeded, after years of investigation, in sensitizing photographic plates for X-ray use by an addition of certain organic salts which are absorbed by the grains of silver bromide on the photographic plate. The plate thus formed is very responsive to the soft rays of an X-ray tube. The soft rays are relatively longer than the hard Roentgen rays. One could compare the soft rays to blue-violet light, if their effects on this new photographic plate are used for the comparison. Photographs taken with such plates give very contrasting effects.

On the “Neo-Roentgen plate” the effect of the yellow light was almost nil. For this reason, developing the plate is considerably facilitated, as the plate can be exposed to yellow light and the attendant, who need not be a skilled operator, can examine the plate in a rather brilliant light without necessarily guessing at possible results. The examination of the plate under a ruby light is, therefore, completely done away with. It follows that if the new X-ray plate should come into general use, much clearer X-ray photographs would be possible; the time of exposure could be decreased; an unskilled operator could develop the plate in a room flooded with yellow light. Such improved plates are now being extensively used.

While not attempting to enumerate all the special affections to which X-ray therapy is now being successfully applied, a few uses may be mentioned.

X-RAYS CURE WHOOPING COUGH

In a preliminary report published in the _Medical and Surgical Journal_ (Boston), Dr. Henry I. Bowditch and Dr. Ralph D. Leonard express the belief that a valuable cure for whooping cough has been found in X-ray treatment of this disease, which has stubbornly resisted most, if not all, of the other remedies applied.

Definite improvement was noted in most of 26 cases of active pertussis (whooping cough) treated with the X-ray, the subjects of which ranged in age from three months to 40 years, with disease stages from one to ten weeks. The physicians added that they could not give any rational explanation of the action through which the X-ray appeared to produce beneficial results. The report said:

“Each patient received three or four applications of the X-ray at intervals of two or three days.”

Many of these cases have not been observed sufficiently long to determine the final result. Nevertheless, “it is evident to us that there resulted a definite improvement in these patients which cannot be explained by mere accident.... It does not seem likely that [the beneficial result] is due to any direct bactericidal property of the X-ray.

“We feel warranted in classifying a small percentage of these 26 cases under the heading of “prompt cures.” By this we mean that after two or three applications of X-rays, covering a period of six days, the spasms and whoops entirely disappeared and the patients were clinically well, except for, possibly, a very slight cough.

“The bulk of the cases, however, we have classified as relieved. This group consists of perhaps 70 percent of the total. By relieved we mean that there has been a gradual diminution in the number of spasms.

“There is a small percentage of cases, perhaps 10 to 15 percent, which apparently were not relieved. In this group are included one moribund case and one rather difficult feeding case.

“While our evidence so far is not sufficient to warrant any definite conclusions, we have the feeling that the X-ray at the present time may be of more value in the treatment of pertussis than any other form of treatment, including serum.”

X-RAYS FOR MALARIA

An Italian physician, Dr. Antonio Pais, of Venice, has since 1916 been successfully treating malaria by means of X-rays. This treatment is, however, not employed as a substitute for quinine, but merely to reinforce its action. The X-rays are directed toward the region of the spleen, and the effect is to reduce its enlargement. At the same time the composition of the blood is modified. The success obtained by Dr. Pais has, according to the _Bibliothèque Universelle et Révue Suisse_ (Lausanne), been so great that the Italian Government decided to introduce his method of treatment into the military hospitals.

Since the war the treatment has been studied by Prof. B. Grassi, who made a report, at an Italian scientific meeting, in which he declared the action of X-rays upon chronic malaria to be “truly marvelous.” The _Bibliothèque Universelle_ says, regarding earlier treatments:

“The attempt was made by them to destroy the parasite contained in the spleen. But it is now known that the X-rays employed for therapeutic action have no effect upon micro-organisms, although they may be injurious to the elements of the blood. In the method devised by Dr. Pais, the X-rays are employed to stimulate the functioning of the spleen, of the marrow, and of the lymphatic elements by means of slight but prolonged excitation; they are employed in infinitesimal doses—homeopathically, so to speak. Thus the result is absolutely different as well as the method.”

Dr. James B. Murphy demonstrated that accompanying cancer grafts on immune animals there occurs a general increase in the circulating lymphocytes and hyperplasia of the lymphoid tissue. When the lymphoid tissue of immune animals was destroyed, the immunibility was annulled. Two methods of increasing the lymphocytes have been found, namely, diffuse small doses of X-rays, and dry heat. Mice with lymphocytosis induced by these agents show Increased resistance to replants of their own tumors. The results afford ground for hope of human application. (Reported in _Scientific American Monthly_, January, 1920, page 96.)

It has been found that actively growing tissue, whether normal or pathological, is the most susceptible to X-rays, and it is comparatively easy to sterilize a number of species of animals without otherwise injuring them. (Prof. James W. Mayor, _Science_, September 23, 1921.) C. R. Bardeen found that X-rays prevent worms from regenerating lost parts. Observations of the effect of exposure to X-rays on the fertility of animals were described in a paper by Prof. L. H. Snyder of the North Carolina College of Agriculture. Exposure of male rats to X-rays, he said, had rendered them sterile at the end of two months, the animals regaining

fertility when no longer subjected to the rays.

If not handled with due caution and skill, X-rays may do more harm than good, provoking malignant growths as well as retarding their development. As early as 1911, Otto Heese published a record of 54 cases of cancer caused by means of improper handling of these powerful rays.

In the early days of X-ray therapy the nature and effects of these radiations were wholly unknown. Operators did not hesitate to test and adjust their tubes by throwing the shadow of their hands on the flouroscope. X-rays do not make objects visible to the human eye, and to see the effects of them it is necessary to interpose a special screen between the eyes and object through which the X-rays are to penetrate. The cardboard screen is coated with a fluorescent substance, such as barium-platinum-cyanide, or calcium tungstate. This screen is best placed in one end of a black wooden or pasteboard box, against the other end of which the eyes are placed when in use.

This screen under the influence of X-rays becomes luminous and enables one to see shadows or silhouettes of objects of denser material interposed between the eyes and the X-ray tube, when the tube is in operation.

CHAPTER III

MARTYRS TO RADIOLOGY

It was not until several years after the discovery of X-rays by Roentgen, in December, 1895—after operators had been severely burned in laboratories and hospitals all over the world, and surgeons and physicians began to compare notes, that the pathological effects of X-rays were discovered and understood.

Says John Macy (in his memorial volume on Walter James Dodd, heroic victim of 50 separate operations due to X-ray burn):

“It is easy now to understand what was happening to Dodd and his contemporaries. In a modern X-ray machine the strength of the current, the quality of the spark, all the conditions, are determined by metrical instruments. In the early days the operator tested his tube and adjusted it by throwing the shadow of his hand on the fluoroscope; by the look of the shadow he judged how the machine was behaving. First he used the left hand until that became too sore, then the right. And until devices were found to focus and confine the rays, the face of the operator was exposed, and sometimes the neck and chest were burned. A limited exposure to the X-ray is as harmless as a walk in the sunlight. It is the repeated, continuous bombardment of the ray that is calamitous. Dodd and the other pioneers lived in the X-ray.”

John L. Bauer was the first victim of the X-ray, in 1906. He was followed in 1914 by Henry Green, who, although he knew he was doomed, and in spite of the fact that he had become almost helpless physically because so much flesh had been cut away in amputating cancerous growths, persisted in his work to the end.

Major Eugene Wilson Caldwell of the Medical Reserve Corps of the United States Army, the inventor of the Caldwell liquid interrupter and other devices for therapeutic use, lost his life in 1918. Dr. Charles Infroit of the Salpetrière Hospital, Paris, died on November 29, 1920. One of Dr. Infroit’s hands became infected in 1898 as a result of his continuous use of the X-ray, and an operation was performed. After that he had 24 other operations, 22 of them performed in the last ten years of his life, the last on August 1, 1920, when his right arm and left wrist were amputated.

Dr. Charles Vaillant, whose heroic services to humanity have made necessary 13 amputations until now he is armless, on February 19, 1923, received from United States Ambassador Herrick the Carnegie plaque, while the cravat of the Paris Gold Medal of the French Legion of Honor was conferred upon the martyr. Physicians say further amputations are inevitable, and that these will result in Vaillant’s death.

In 1921, the eminent English radiologists, Dr. Cecil Lyster and Dr. Ironside Bruce, and Dr. Adolphe Leroy of the St. Antonie Hospital in Paris, died martyrs to their noble profession. “All of these men went knowingly to death. Perhaps they did not take their sacrifices in the spirit of the saint, possessed by a vision of suffering humanity. Theirs may have been the ardor of the scientist, the endurance of a worker who hears the challenge of nature’s silence and goes to battle. But in themselves they express the powerful urge of a spirit that longs to see, to feel, to know, and to possess all the mysteries of the universe. It is the same spirit that makes men rebel and agonize for a better order of humanity. These men seem better than the world that produces them. But each of them, when he dies, may pull the rest of humanity a little closer to his level.”

Dr. Frederick Henry Baetjer of Johns Hopkins Hospital has only two of his ten fingers left. He lost the other eight as the result of burns received in X-ray experimentation.

Dr. Francis Carter Wood, X-Ray and radium expert of the Crocker Special Fund Cancer Laboratory of New York, calls particular attention to the fact that “the deaths which are occurring now are the results of repeated exposures ten or more years ago, when no one knew what the effect of the rays might be. The burns suffered then were the result of continuous exposure without protection against the rays. One exposure, or a moderate number of them, would do no harm; but before the present perfection of the apparatus it was necessary to adjust the focus for each picture, and the operator would do this by looking at his bare hands through the fluoroscope. This resulted in chronic burns, and the burned flesh formed a fertile soil for cancer. Lead one-quarter of an inch thick will stop both radium and X-rays.”

In Dr. Wood’s opinion, workers in X-rays today “need not suffer any ill effects except through their own carelessness.”

A discovery which promises to put an end to the dangers to life and limb risked by those who engage in working with X-rays was communicated to the Academy of Sciences of Paris as early as May, 1920. It is the result of experiments by Dr. Pesch of the Faculty of Montpelier, who himself is one of the sufferers from X-rays, and who has long been seeking the means of protecting his young confrères.

He found that deep red rays are antagonistic to the ultra-violet rays which produce irritation and burning of the skin, and certain oxidations. Thus, by the simultaneous application of both rays he secures immunity for X-ray workers. He has already proved that erythema can be prevented by the application of red rays. Daniel Berthelot, who announced the discovery to the Academy, recalled that as long ago as 1872 the antagonism of extreme rays of the spectrum had been foreseen by Becquerel in his study of phosphorescence.

Dr. Pesch employs a filter composed of a plastic material that allows only the red and yellow rays to pass. It is claimed that by means of this filter not only are the X-rays made harmless, but its employment effects a cure for radio-dermatitis, the affection which has maimed or killed so many of the early workers in X-ray therapy.

According to Dr. G. Contremoulins, Chief of the principal laboratory of the Paris hospitals, whose researches and experiments were begun in February, 1896, the usual methods of protection even today are not always adequate. Says he (in _La Démocratie Nouvelle_, Paris, April, 1921):

“Young radiologists, especially those born of the war, take no heed of the experience acquired by their elders, being quite convinced that the glasses, gloves and aprons containing lead offer a perfect protection—they even imagine that strictly speaking they might get along without them.

“Like a child which hides behind a wooden door to shield itself from the bullets of a machine gun, our young radiologists believe they are safe when they have donned their gloves and examine their patients behind a sheet of lead glass. But, unfortunately, these enable them only to avoid those superficial skin affections caused by the most absorbable rays of the spectrum.

“But they receive, alas, those other radiations which are more penetrating, and these slowly produce lesions of all the ductless glands in the body, whose internal secretions we now know to be of such vital importance in the bodily economy.”

The modern employment of 200,000 volts under three milliamperes gives rise to the need of great caution in the use of X-rays. Even the health of persons in adjoining rooms or buildings, Dr. Contremoulins believes may be imperiled. In the _Popular Science Monthly_ for October, 1921, this veteran radiologist makes some startling revelations. To quote a few passages:

“In April, 1896, five months after the discovery of X-rays—or Roentgen rays, as they are also named in honor of their discoverer—a pose of eight hours was required for a correct radiograph of a profile head, the tube being placed ten inches from the sensitive plate.

“In April, 1921, a similar image was obtained in four hours at a distance of 90 yards from the apparatus. This means that the radiation with modern apparatus is more than 20,000 times stronger than was possible in 1896.

“With the very weak radiation that I have used for my experiments, corresponding to the ordinary radiographic and radioscopic work, it has been easy for me to obtain images of metallic objects and human bones placed on a sensitive plate 15 feet from the radiating source, although the rays pass directly through a slab of marble an inch thick, a sheet of lead one-tenth of an inch thick,

and a flooring eight inches deep, built of oak boards and rough plaster.

“Fifty feet from this same source I have been able in four hours to fog a photographic plate placed behind a wall of brick and stone 20 inches thick. Also in the same time I have obtained a correct radiograph of a skull and a crab, 262 feet from the X-ray machine. All these experiments were made with a 17-centimeter spark and two milliamperes of current.

“If photographic plates are so readily affected by these rays, we must admit that animal cells also are affected to an appreciable degree. The X-rays that are being used to cure a patient may at the same time inflict radio-dermatitis on other persons exposed to their influence in adjoining rooms or buildings. Nothing will suffice for safety but to cover the walls and floors of X-ray rooms with sheets of lead from a quarter to half an inch thick, according to the power of the source and its distance from the lining....

“Biologic reactions from X-rays take two forms. The first is a skin lesion known as radio-dermatitis, caused by the skin’s absorbing a large quantity of radiations. The second results from the improvements in X-ray tubes and the use of filters absorbing the radiations of long wave length, currently named ‘soft radiation.’ This reaction takes place deep beneath the skin upon the active cells that are the most vulnerable. It is principally the internal secretion glands that are affected. Among those who continually receive even weak doses, a gradual lessening of vitality takes place, leading slowly to a physiological impoverishment that inevitably carries them off sooner or later.”

Dr. Contremoulins was able to escape serious injury up to the outbreak of the World War, but is now a victim of his services to wounded soldiers. As a result of his efforts—and due also, partly, to suits brought against a Paris physician by neighbors who alleged that their health had been impaired, resulting (perhaps) in two cases of cancer—a thorough-going investigation was undertaken by the French Ministry of Hygiene.

Dr. Declere of the Academy of Medicine presided over a committee which included Mme. Curie, M. Becquerel, a radiologist; Dr. Vaillant and a number of specialists. A leading member of the Academy said he did not believe that X-rays menaced persons who did not come into direct contact with them.

“I intend to study the question by three methods,” he said. “First, we shall make a purely physical examination, studying the action of the rays and in what measure they exert themselves at certain distances. Second, we shall experiment with the living tissues of rabbits, trying various distances several hours a day and noting the effect on the red and white corpuscles and glands of the animals. Then, since it is impossible to make such experiments on human bodies, we shall collect data based on 25 years’ experience with X-rays to see whether physicians in close contact have been burned.”

While X-ray treatment cannot be said to _cure_ a deep-seated cancer, it is undoubtedly being given with highly beneficial results in many cases, alleviating much suffering and retarding the growth of malignant tissues.

As is well known, tuberculosis can advance to a dangerous stage before it exhibits physical symptoms recognizable by physicians. The X-ray not only brings to light incipient consumption, but reveals the exact place and extent of the lesion. Any abnormalities of the alimentary tract, also, may readily be brought to view, as well as certain effects produced on certain arteries, due to arterio-sclerosis or to angina pectoris (a very painful form of heart disease).

It has been well said that “the list of diseases, the presence and extent of which are betrayed or confirmed by the X-ray, would fill pages and would include most of the enemies to human health. Among them may be mentioned many forms of tuberculosis, occult abscesses whose ramifying consequences physicians were once unable to refer to their source, tumors, cancers, kidney stones, gastric ulcers, diseases of the heart.”

The martyrdom of radiologists has not been in vain.

In cases of emergency, X-ray diagnosis may now be given patients in their own homes. A surgical X-ray outfit that can be carried in an ambulance and taken to the bedside of a patient too ill for removal to a hospital passed a successful trial in England, thus adapting an emergency war-time arrangement to civilian use. A generator in the ambulance operates the tube, which has a special mounting that enables it to be placed over the patient’s bed, and adjusted for height and position by hand-wheels. The control apparatus is mounted on a separate stand, and connected with the ambulance outside by a cable wound on a reel. Provision is made for developing the exposed plates at once, so that a diagnosis can be made in a few minutes.

CHAPTER IV

DISCOVERY AND NATURE OF X-RAYS

In March, 1923, there passed from this world one of the most beautiful exemplars of the true scientific spirit that earth has ever seen—Dr. William Conrad Roentgen, F.R.S., Professor of Experimental Physics in the University of Munich, the discoverer of X- or Roentgen Rays.

Born at Lennep, on March 27, 1845, Professor Roentgen filled a number of important posts before his death in 1923, in which year he was awarded the Nobel Prize in Physics—an award which brought with it a gift of $40,000. Although suffering from the poverty which resulted in Germany as an aftermath of the World War, Professor Roentgen refused to utilize the Nobel Prize award for his own personal uses. He gave the entire sum to a research society to enable other students to carry on their investigations.

While occupying the chair of Professor of Physics and Director of the Physical Institute at Würzburg, Dr. Roentgen made the discovery—in 1895—for which his name is chiefly known—though his researches led to important advances in several other departments of physics.

While experimenting with a highly exhausted vacuum tube on the conductivity of electricity through gases, Dr. Roentgen noticed that a paper screen covered with potassium platinocyanide—a phosphorescent substance—which chanced to be lying nearby, became fluorescent under action of some radiation emitted from the tube, which at the time was enclosed in a box of black cardboard. Professor Roentgen then found, by experiment, that this heretofore unknown radiation had the power to pass through various substances which are impenetrable to ordinary light-rays. He found that if a thick piece of metal—a coin, for example,—were placed between the tube and a plate covered with the phosphorescent substances, a sharp shadow was cast upon the plate. On the other hand, thin plates of aluminum and pieces of wood cast only partial shadows.

Thus was it demonstrated that the rays which produced the phosphorescence on the glass of the vacuum tube could penetrate bodies quite opaque to ordinary light-rays. Like ordinary light, these rays affected a photographic plate; but owing to their peculiar behavior in regard to reflection and refraction, Roentgen was led to put forward the hypothesis that the rays were due to longitudinal, rather than to transverse waves in the “ether.” They will ionize gases, but they cannot be reflected, polarized or deflected by a magnetic or electric field, as are ordinary light-rays. (It has been shown that the _scattered_ secondary rays show polarization.)

Being in doubt as to the real nature of these penetrating rays, Roentgen called them “X-rays.”

In 1896 Professor Roentgen was the recipient of the Rumford Medal of the Royal Society. This honor was shared by his compatriot Philipp Lenard. Lenard was the discoverer of the rays emanating from the outer surface of a plate composed of (any) material permeable by cathode rays. By impinging on solids, the cathode rays (negative electrons) generate X-rays. “Lenard rays,” which are similar in all their known properties to cathode rays projected from the cathode of a vacuum tube, do not emanate from the cathode. (Unlike the X-rays, cathode rays may be deflected from their natural course along “straight lines” by the application of a magnetic or electric field.) Professor Lenard, as also Hertz, discoverer of the now well-known “wireless waves,” had already demonstrated that a portion of the cathode rays could pass through a thin film of a metal such as aluminum.

When Roentgen rays (X-rays) are allowed to fall upon any substance, the matter emits cathodic (or secondary Roentgen) rays. “The characteristic secondary radiation may be compared with the phosphorescence produced by ultra-violet light, and the cathodic secondary rays with the photoelectric effect” (Sir J. J. Thomson).[2]

The penetrating power (“hardness”) of these rays appears to be determined solely by the nature of the elements in the emitting substance. The velocity of the cathodic (or secondary Roentgen) rays seems to be quite independent of the matter exposed to the primary rays, but increases as the hardness (penetrating power) of the primary Roentgen rays increases.

The _character_ of the emitted rays, in brief, appears to be quite unaffected by the chemical or physical condition of the element. Red-hot iron, for example, exhibits the same characteristic Roentgen radiation as iron at room temperature. But the _penetrating power_ (hardness) of this characteristic (emitting) radiation increases gradually and continuously with increasing atomic weight of the emitting elements. The complete independence of the penetrating power of the characteristic Roentgen radiation from external surroundings indicates strongly that it is closely connected with the nature of the nuclei (“cores”) of the atoms giving rise to it.

FOOTNOTES:

[2] When ultra-violet light is allowed to fall upon a metal it causes the metal to emit electrons and thus to acquire a positive charge, the velocity of the emitted electrons being exactly proportional to the frequency of the incident light. Or when light of X-ray type falls upon the surface of almost any substance, it takes hold of an electron in the atoms of that surface and hurls it out into space with a speed exactly proportional to the wave length of the light. This phenomenon is known as the photoelectric effect.

CHAPTER V

ULTRA-VIOLET LIGHT IN HEALTH AND DISEASE

That both the compound rays of ordinary sunlight and ultra-violet rays ("artificial sunlight") are highly effective in the treatment of a number of complaints is now well known. They are both in general use for the external treatment of rickets, tuberculosis, and a number of other diseases. Light-rays are also applied to hasten the healing of wounds.

The use of the sun as a healing agent seems first to have been developed in a scientific way by Dr. Neils R. Finsen, a young Danish physician who was later awarded the Nobel Prize in Medicine. His original researches were undertaken toward the end of the 19th century. Then Dr. Rollier opened the first sunlight clinic in 1903, and in 1910 established his school at Leysin, in the Alps. Dr. Rollier is now treating about 1,000 patients, mostly afflicted with various forms of tuberculosis of the bone. The sun cure is also used to some extent for pulmonary tuberculosis, and with considerable success. (See my _Man's Debt to the Sun_, Little Blue Book No. 808, Chapter IV.)

According to Dr. Rollier, exposure of the diseased to the sun's rays is efficacious in the treatment of anemia, malnutrition, bone and gland infections and various types of tuberculosis, and is a body builder for convalescents. On the outskirts of San Rafael, California, is a novel sun sanitarium, Helios Sanitarium, modeled after the Alpine sanitaria of Dr. Rollier.

Two investigators have recently studied the comparative germ-destroying power of the blood in healthy and ill persons, before and after exposure to sunlight. It was found that the germ-killing power of the blood was increased when the sun bath lasted for a certain length of time. It was shown that too long or too short an exposure decreased the blood's power. It was decreased also in patients who had fever. Several other conditions were found to influence the results. Physicians believe that several points of practical value may emerge from these experiments. One important and useful result is that they offer a new method to guide and gauge the effects of treatment in tuberculosis and other diseases.

The practice of X-ray treatment (since 1910 included under the more general term _radiotherapy_) includes treatment not only by X-rays, but also by all kinds of rays—treatment by heat, by the sun's rays, by ultra-violet rays, and even by violet rays. The rays of radioactive substances used in medicine come under the etymological term of radiotherapy. But in general practice, amongst radiologists, the term is applied to treatment by X-rays alone. Nevertheless, it is now well established that the ultra-violet rays are not only bactericidal, but that they also play an important role in the treatment of certain diseases, and in the maintenance of good health. On the other hand, these rays produce a certain irritability among persons of the white race in the tropics, which cannot be regarded as healthful in their general effects.

Since the amount of ultra-violet light coming from the sun has been shown by Abbott to be variable, it may be that some of the irritability which seems to be general among the inmates of our public institutions on certain days is due to this change in the sun's outpour of ultra-violet radiation. As Dr. E. E. Free remarked not long ago:

"Put these facts together. Ultra-violet rays affect life. The amount of ultra-violet coming from the sun is variable. Does this mean that some of the obscure, day by day variations of health can be due to this? Some days everybody seems happy and cheerful. Other days everybody is depressed. Still other days are breeders of 'nerves.' Maybe the ultra-violet does it. Maybe not. Doubtless the investigators will find out presently."

Recent experiments at the Maine Agricultural Experiment Station, conducted under the direction of Dr. John W. Gowen, have led to the important discovery that milk from cows that have been treated with ultra-violet light, from mercury-vapor quartz lamps, contains a much larger amount of the substance—presumably a vitamine, or vitamines—that prevents rickets in children and young animals. At any rate, it was found that the milk from cows deprived of sunlight and ultra-violet light was quite deficient in the anti-rachitic factor. Animals and birds fed on the sunless milk uniformly developed rickets.

The Holstein-Friesian cows used in the experiments were of nearly the same age and calving date and all received like treatment as to feed, temperature, etc., and stood side by side in the same barn. "Throughout the treatment," says Dr. Gowen, "these cows

did not leave the barn. For one month none of the cows received ultra-violet light. For the second month two cows received ultra-violet light 15 minutes a day, generated from a Cooper-Hewitt alternating current light at three feet above their backs. For the third month these cows received ultra-violet light for 30 minutes a day under the same conditions. In the meantime Rhode Island Red chickens were allowed to develop rickets, shown both clinically and by X-ray photographs. They were divided into two lots, one lot of these chickens receiving milk from the ultra-violet cows, the other of two lots of chickens, milk from the control cows. Both lots received all the milk they wished.

The chickens have now been under treatment 50 days. The lot receiving milk from cows exposed to ultra-violet light are in good condition with no appearance of rickets in X-ray plates. The lot receiving normal milk has moved progressively toward more extreme clinical and X-ray rickets. The experiment was repeated, using the milk from these same cows on White Leghorn chickens showing clinical and X-ray rickets. Five chickens were in each lot. After 38 days' treatment four of the lot receiving milk from the ultra-violet cows are almost cured of rickets, showing only a very slight stiffness. The fifth chicken shows some stiffness. Four of the lot receiving the normal milk show constantly increasing symptoms of the more advanced stages of clinical rickets.

These results point to the conclusion that more of the substance necessary to cure rickets is absorbed by the cow exposed to ultra-violet light and secreted by her in her milk. The cows prevented from receiving ultra-violet light are not able to secrete this anti-rachitic substance in sufficient quantities to cure or allay the process of clinical rickets. The results thus point to an environmental factor transmitted by the cow to her offspring through the medium of her milk. They further suggest that the high incidence of rickets in children during the late winter months is due to their mothers not receiving ultra-violet light either during pregnancy or while in lactation. Furthermore, it would appear that cows' milk produced especially for baby-feeding should be from cows which have access to ultra-violet light either from the sun or from some other source.

Dr. C. C. Little of the University of Maine, and his associates, fully demonstrated the value of sunlight to animal life through experiments on a flock of 233 chicks. The chicks were divided into three groups and all were given the same diet. One group was kept in natural sunlight, the second was kept in sunlight that went through window glass, and the third was given both natural sunlight and extra ultra-violet rays produced artificially. The last class grew the best. The class that got only natural sunlight grew normally. The class kept behind window glass all developed bone disease. The glass of the greenhouse allowed the light of the sun and the heat of infra-red rays to get through. But it screened out the ultra-violet waves.

The beneficent effects of invisible ultra-violet rays are seen in both the organism exposed to them and the food consumed. This is true whether the rays come direct from the sun or by means of a quartz lamp. Ordinary glass lamps prevent the ultra-violet rays from passing out. But not all kinds of foodstuffs by any means are favorably affected by the rays. Only those foods which contain fat seem to be materially improved. The value of milk and of cod liver oil is greatly enhanced by exposure to the rays. Dr. Benjamin Kramer has been highly successful in treating babies affected with rickets by subjecting milk itself to the action of ultra-violet light.[3]

As early as 1923, it had been shown by feeding experiments with various types of animals at the University of Wisconsin that sunlight was acting either directly upon the animal or upon its food. The same dietary was found to produce contradictory results. It was established—especially by H. Steenbock and E. B. Hart—that sunlight is indispensable to man and beast, in that it is the determinant of the efficiency with which calcium can be assimilated and retained. (See their report, _Journal of Biological Chemistry_, Vol. 62, page 577, 1925.) Calcium, it is pointed out, needs to be conserved because in proportion to the body needs it is not found abundantly in foods and feeds. Steenbock and Hart tell us that sunlight plays the particular rôle of conservator "by virtue of its content of ultra-violet radiations of approximately 250 to 302 millimicrons in wave-length, but unfortunately these are not present in sufficient degree to provide a wide margin of safety for the animal. As a result we have rickets in the young and poor dentition, restricted lactation, abortion and impoverishment of the skeleton in lime to a dangerous extent in the adult.... The ultra-violet rays bring their effect through the medium of certain compounds widely distributed in plant and animal tissue, so that practically any foodstuff can be 'anti-rachitically' activated. 'Make hay while the sun shines' is more than a mere poetic slogan, for hay made in the dark is devoid of rickets-preventing properties" (_Science_, December 4, 1925).

The careful experiments of J. S. Hughes showed that chickens receiving a standard scratch feed and mash, supplemented with sprouted oats and buttermilk, developed rickets (weak legs) when deprived of direct sunlight. Chicks receiving the same feed but given sun baths developed normally, although they were confined in a very small pen, with little opportunity to exercise. Light from ordinary electric bulbs had very little, if any, beneficial action. Light from the Hereus mercury arc lamp was very beneficial. Cod liver oil also proved to be effective in preventing rickets in chickens as in mammals.[4]

That such fats as olive oil and lard may be activated by exposure to ultra-violet rays and used as a substitute for cod liver oil in the treatment of rickets is evidenced by experiments reported by the Department of Agricultural Chemistry of the University of Wisconsin. In the series of experiments now published, olive oil and lard were exposed to the action of the ultra-violet rays from a powerful mercury-vapor quartz lamp, for periods of time ranging from half an hour to 17 hours.

After exposure to the rays these fats were fed to a group of experimental rats in which rickets had been produced, and the activated olive oil and lard were found to have the same beneficial results that follow the administration of cod liver oil. The weight of the rats increased and an analysis of the bones showed an increase in the calcium content.

Some of the activated olive oil, which had been stored in a stoppered bottle, showed no change in potency ten months later. It was found also that the fats might be activated by the rays from the open carbon arc, the iron arc, and sunlight; but that exposure for such prolonged periods as 17 hours destroyed their potency. This destruction took place even on cod liver oil.[5]

It has long been known that human tissue is more actively changed by light when it has been “sensitized.” Quinine, esculin, fluoresceine, etc., are examples of tissue sensitizers, in addition to their other effects. The most powerful of all known sensitizers is haemato-porphyrin—or simply “porphyrin.” This sensitizer is a purple substance closely allied to the haemoglobin that gives blood its red color. Subtracting its iron and albumin from haemoglobin by appropriate chemical processes leaves porphyrin. This substance reacts strongly to the ultra-violet rays, in rare cases causing a disease which turns the teeth to a deep purple hue. Victims of this uncommon ailment have to wear gloves constantly, and when going out of doors during the day time must put on heavy veils.[6] Porphyrin is capable of dissolving the red corpuscles of the most dissimilar animals in the presence of sunlight. But neither the haemato-porphyrin nor the light alone is capable of injuring the animals. Only the combined effect of the two can harm them. A physician experimentally injected an exceedingly minute quantity into himself and then exposed himself to a moderate light, and became very ill.

Hausmann found that even the diffused sunlight of an early spring day in Vienna was sufficient to cause the death of white mice which had been subjected to small quantities of this strange substance. Dr. E. C. Van Leersum, of Holland, proved by experiments with rats that the utilization of lime by our bodies can be controlled almost at will by this “sensitization” process. Rickets, or a condition indistinguishable from rickets, can be produced or cured by proper control of the sensitization.

SUNLIGHT AND INFANTILE PARALYSIS

An article by Science Service, quoted in _Science_, September 11, 1925, says:

Another of the dreaded diseases of childhood, infantile paralysis, which, like rickets, graduates large quotas of cripples, has responded to the good influence of the sun’s rays. Dr. G. Murray Levick, medical director of the Heritage Craft Schools at Chailey, Sussex (England), who originated the treatment, said that no other method has ever had as good results as this in the treatment of infantile paralysis.

Dr. Levick first deduced that neurasthenia in grown-ups and rickets in the young are due to the same cause. Both these diseases, he claims, are nutritional disturbances of the nerve centers affecting the bones in the young, and the nervous systems in the old. The action of sunlight on the skin forms a substance which is carried into the blood and feeds the nerve centers as well as the bones. His success in treating neurasthenia with sun’s rays led him to apply it to cases of infantile paralysis, a disease which is a severe shock to the nervous system and which results in muscular atrophy. Under the action of sunlight a renutrition of nerve centers takes place.

Synthetic sunlight produced by him with an electric arc light of his own invention proved as good as natural sunlight, and could be better regulated to the patient’s endurance. He used two distinct kinds of light-rays, the short ultra-violet rays for nerve nutrition, and the long red and infra-red rays for muscle treatment. Red rays, as can be seen when the hand is held up against the sunlight, penetrate the flesh to a considerable extent, and can therefore stimulate the sleeping muscle.

Dr. Levick warns that immediate success must not be expected. He has found constant improvement where short daily treatments were continued over a period of several years. While the method may not be effective in extreme cases, it is nevertheless a test which will soon show after a few treatments whether any rejuvenation of the nerve fiber is taking place.

It is now admitted that the (red) heat-waves may play some part in heliotherapy—exposure to direct sunlight for medical purposes. Dr. Lazarus-Barlow, Professor of Experimental Pathology in the University of London, concludes that even though heat-rays may

also play some part in curative processes, “experience of the treatment of wounds by sunlight in France during the World War indicated that a degree of benefit arises from exposure to sunlight which cannot be attributable to warmth and ultra-violet rays. On the other hand, in the Finsen light treatment of lupus (a tubercular affection of the skin of the face, occurring in several forms) and in the treatment of tuberculosis at high altitudes, ultra-violet rays play a predominant part.”

As the ultra-violet rays penetrate but a fraction of a millimeter into the epithelium, “it is uncertain how the rays act.” The suggestion is here ventured that since the recently discovered Millikan Rays are particularly powerful under the same conditions that make application of the ultra-violet rays practicable as a therapeutic agency, it may later be found that these highly penetrating rays, of exceedingly short wave length, aid greatly in effecting some of the cures now attributed wholly to the longer (and less penetrating) ultra-violet rays or the much shorter X-rays.[7]

Professor Lazarus-Barlow calls attention to the fact that it is precisely those tubercular persons who tan easily who are said to derive the greatest benefit from a sojourn at high altitude.

Very remarkable is a recently adopted machine which “pours ultra-violet light through a funnel down the throat of a patient.” The new apparatus, first used in London, is employed for treatment of various mouth and throat diseases, “thus making it possible for patients to take internal baths of artificial sunlight” (_Science_, February 26, 1926).

In England, where the sky is so often overclouded, it is natural that much attention has been given to ultra-violet ray therapy. A recent press dispatch tells us:

“London recently had 23 consecutive days on which no beam of the sun could force its way through the mantle of cloud and fog which spread over that section of England. Now the Britons are making artificial suns that may be available for both indoor and outdoor illumination. Arc lights throwing powerful ultra-violet rays are being installed in beauty shops and hotels, and patrons are given opportunity to bathe their bodies in this brilliance. These rays are being billed as more potent than sun baths, and citizens who have small chance to see the orb of day get their sunshine and their medicine at one swoop.”

Two Indian scientists, S. S. Bhatnagar and R. B. Lal, of the University of the Punjab, Lahore, discovered in 1925 that germs grow faster when exposed to “polarized” light than to ordinary light. (Ordinary light—according to the undulatory theory—is due to vibrations transverse to the direction of the ray, but varying so rapidly as to show no particular direction of their own, the fronts of the light-waves crisscrossing at all angles. When, by any means, these vibrations are given a definite direction, the light is said to be _polarized_, the fronts of the waves being all arranged in the same direction, though the path of the rays may be plane, elliptical, circular, or rotary, according to the method of polarization employed.)

The Indian experimenters took cultures of the germs of typhoid fever and cholera, and exposed one set to ordinary light, and another to a beam of polarized light. The latter multiplied much faster than did the germs under ordinary light.

It was demonstrated in 1925 by Dr. Elizabeth S. Semmens, of Bedford College, London, that the digestion of starch takes place more readily under polarized light than in ordinary light.

Prolonged exposure to the ultra-violet rays will destroy any germs known to science. (Cathode rays—which are shorter than ultra-violet rays—will kill not only germs, but insects as well, by means of a device developed by Prof. W. D. Coolidge.)

“Bacteria,” says Dr. Coolidge, “have been rayed, and an exposure of a tenth of a second has been found sufficient to kill even highly resistant bacterial spores. Fruit flies, upon being rayed for a small fraction of a second, instantly showed almost complete collapse, and in a few hours were dead.”

This may lead to the application of cathode rays as a germicide, but their effect on higher forms of life shows that their unskilled use would be most dangerous. For example, Dr. Coolidge relates:

“The ear of a rabbit was rayed over a circular area one centimeter in diameter for one second. After several days a scab formed which fell off a few days later, taking the hair with it. Two weeks later a profuse growth of snow-white hair started which soon became much longer than the original gray hair. Another area was rayed for 50 seconds. In this case, scabs developed on both sides of the ear, which scabs later fell out, leaving a hole. The edge of this hole is now covered with snow-white hair.”

A very interesting problem to scientists relates to the question as to whether or not insects are color-blind. It may be that we now have at least a partial answer to this vexed question, and in terms of ultra-violet radiations.

Dr. Frank E. E. Germann, of Cornell University, calls attention to some recent experiments which show conclusively that at least one kind of insects (flies) have a range of vision in the ultra-violet, just as we have in the visible spectrum. It was also made “perfectly evident that flowers do have their characteristic ultra-violet radiations” (_Science_, March 26, 1926, page 325). It is due “to our own egotism that we call the insect color-blind.”

A given type of insect might in reality be visiting flowers of the same color as far as it was concerned, while to us it appeared to be visiting flowers of all colors. “Might not two flowers, one red and one blue, both give out the same group of wave lengths in the ultra-violet, and thus be identical in color to an insect seeing only the ultra-violet? Moreover, what is to prevent two different kinds of red flowers from giving out two entirely different sets of wave lengths in the ultra-violet, and thus appearing to have entirely different colors to an insect?”

In a very real sense, science is only at the beginning of the discoveries it will yet make in its investigations of the nature and action of ultra-violet, cathode and X-rays.

FOOTNOTES:

[3] It is interesting to note in this connection that Kuzelmass and McQuarrie have suggested that oxidation of cod liver oil gives rise to ultra-violet radiation. (See _Science_, September 19, 1924.)

[4] Paper read before the 66th meeting of the American Chemical Society, held in Milwaukee, Wis., September 10th to 14th, 1923.

[5] Dr. Harriette Chick and her co-workers of the Vienna University Child Clinic discovered, first, that the action of cod liver oil on the bone-lesions of rickets has an exact parallel in that of the ultra-violet rays of sunlight, or of the rays from a mercury-vapor quartz lamp; and, second, that the oil and the rays were effective substitutes the one for the other. See my _Man’s Debt to the Sun_, Little Blue Book No. 808, page 49.

[6] The only creature that has porphyrin as part of its normal body-covering is a tropical bird called the touraco, parts of whose feathers are dyed a brilliant red by a porphyrin-copper compound known as turacin. This pigment is remarkable also because it seems to be the only normal occurrence of copper as a coloring compound in feathers or skin. Turacin is soluble in weak alkali, so that when it rains and the bird comes into contact with such alkaline solutes as frequently occur in nature, the turacin bleaches out! Although porphyrin is rare as a normal coloring in adult animals, it is the commonest pigment found in the shells of birds’ eggs. Almost all eggs, from the hen’s brown to the robin’s blue, contain it.

[7] The length of the very short X-rays was accurately determined by a new method developed by Compton and Doan in 1925, and was found to be about three billionths of an inch.

APPENDIX 182 INDEX 185

PREFACE.

One of the reasons for the popularity of secret remedies is their secrecy. It is a case in which the old saying _Omne ignotum pro magnifico_ applies. To begin with, there is for the average man or woman a certain fascination in secrecy. The quack takes advantage of this common foible of human nature to impress his customers. But secrecy has other uses in his trade; it enables him to make use of cheap new or old-fashioned drugs, and to proclaim that his product possesses virtues beyond the ken of the mere doctor; his herbs have been culled in some remote prairie in America or among the mountains of Central Africa, the secret of their virtues having been confided to him by some venerable chief; or again he would have us believe that his drug has been discovered by chemical research of alchemical profundity, and is produced by processes so costly and elaborate that it can only be sold at a very high price.

The British Medical Association considered, therefore, that it would be useful if not instructive to make analyses of some of the secret remedies, the virtues of which are so boldly advertised, especially in popular monthly magazines and weekly newspapers, and in diaries and almanacks pushed under the front door or dropped over the area railings. The results are given in the following pages; they have been classified under various heads, according to the particular kind of disorder for the cure of which the preparation is more particularly vaunted. The claims in some instances are so comprehensive that it has not always been easy to assign the nostrum its proper place, and for a few it has been necessary to institute a chapter on Cure Alls.

An inquiry of the kind is, from the analytical point of view, tedious and often difficult; for though the analytical chemist can easily and quickly identify the nature of inorganic salts in a mixture or powder, and estimate their amount, most vegetable drugs which exert any appreciable effect on the body owe their power to the presence of an alkaloid or glucoside. The active principle of opium, for instance, is morphine; that of cinchona bark, quinine; that of belladonna, atropine, and so on, and the chemist can recognise any alkaloids present in a mixture or pill. It is otherwise, however, with vegetable extracts and colouring matters, for which

pharmaceutical science has not yet been able in all cases to supply easily applicable and conclusive tests, because for the most part they contain no active principle and are used in pharmacy for their agreeable odour or bitter taste, as vanilla or sorrel are used in cookery. Of the accuracy of the analytical data published there can be no question; the investigation has been carried out with great care by a skilled analytical chemist, who has controlled his results in various ways, one being that in every doubtful case the formula obtained by analysis has been tested by making it up and comparing the appearance, taste, and physical properties of the imitative mixture with those of the secret preparation sold to the public.

The articles in this volume have not been confined to a mere dry statement of the results of analysis. Care has been taken to reproduce the claims and exuberant boasts of the vendors, and the contrast between them and the list of banal ingredients which follow must strike every reader. This juxtaposition of analytical facts and advertising fancies is instructive and sometimes entertaining, the fancy is so free and the fact so simple.

It must not be assumed that the concoctors of these mixtures and powders and ointments show any particular skill in the compounding of drugs. On the contrary, they appear curiously indifferent to taste and appearance, and perhaps count on the belief, common among the poorer classes at least, that the nastier a drug the more effective it is. There is, at any rate, the excuse for this belief that the effort to subdue the repugnance to the draught produces a glow of virtue which may perhaps have a certain stimulating effect on the mind; the patient having not only spent his money but suffered some discomfort, is anxious to justify his faith by assuming himself to be the better for the double sacrifice.

It is not, however, only the poorer classes of the community who have a weakness for secret remedies and the ministration of quacks; the well-to-do and the highly-placed will often, when not very ill, take a curious pleasure in experimenting with mysterious compounds. In them it is perhaps to be traced to a hankering to break safely with orthodoxy; they scrupulously obey the law and the Church and Mrs. Grundy, but will have their fling against medicine. Usually, however, people of these classes take to some system. It used to be electricity or hypnotism or some eccentricity of diet; nowadays it is more often Christian Science.

Judging from the relative number of secret remedies advertised for different complaints, it would seem that the most attractive fields for exploitation by the “patent” medicine man are afforded by those diseases which are widely prevalent, and sufficiently serious to cause considerable suffering and incapacity, inasmuch as such disorders lend themselves to sensational descriptions of the dire consequences which will follow if the one and only real and certain cure is not purchased.

The estimates of cost given throughout the volume refer only to the ingredients, the prices of the various drugs being those quoted in an ordinary wholesale drug list, and take no account of the cost of bottles, boxes, wrappings and packages, very often a much more serious source of expenditure. The stamp duty levied by the Inland Revenue under an old Act of Parliament must also be taken into consideration, but, ostensibly at least, it is paid by the purchaser, for the full price of a nostrum is usually 1s. 1½d. or 2s. 9d. and so on, the extra 1½d. or 3d. representing the value of the stamp. “Store prices” have, however, invaded this, like most other fields of enterprise.

CHAPTER I.

CATARRH AND COLD CURES.

The analyses here given of some of the proprietary articles which the public are induced to buy for the cure of ordinary colds and catarrh furnish a good example of the absurdity of the barefaced pretensions in which nostrum mongers indulge, for minor ailments are by no means neglected by the makers of nostrums; if the price to be obtained is somewhat lower than in the case of more serious disorders the cost price can be reduced in an equal or greater proportion. Alarming accounts, too, of the evils to be expected if resort be not had to the advertised articles are not wanting. Thus, in the advertisement of one of the articles described below, it is stated that catarrh “invariably creates biliousness, constipation, pleurisy, asthma, bronchitis, catarrhal fever, and consumption”; also that “it is estimated that over 20,000 people died in the United Kingdom last year of consumption caused by catarrh.” The remedy put forward for this malignant disease is shown by analysis to consist of a solution of a pinch of common salt with a trace of carbolic acid, the actual cost of the quantity sold for a shilling being one-thirtieth part of a farthing. The probability that many people would regard a slight cold in the head as not requiring a resort to a “specialist in chronic disease in every form” such as the proprietor of this preparation, is turned to account by a disparaging reference to the medical profession. “Catarrh,” we are told, “in its chronic form (and the complaints arising from it) is a malady which has not, up to the present time, received that attention and research from the medical faculty which it deserves. Most practitioners have given it merely a passing thought, or

poohed at it as a mere cold which would soon pass off, and perhaps give some light tonic to tone up the stomach." Another of the "remedies" described well illustrates the way in which the public is deluded by such "specialists"; camphor, quinine and ipecacuanha are frequently employed as domestic remedies in the early stages of a cold in the head, and persons who believe in their usefulness can no doubt be induced to buy a "cold cure" which professes to contain them in combination with other drugs, presented in a form convenient and agreeable to be taken; but in the tablets which are represented as consisting of cascara, bromide, quinine, ipecacuanha, camphor and bryonia, analysis did not reveal any appreciable traces of cascara, bromide, quinine, ipecacuanha, or camphor. The principal ingredients actually present were cinchonine, an alkaloid found in the bark from which quinine is prepared but cheaper than quinine, and acetanilide, a chemical better known under the name antifebrin, both in very small doses.

Many proprietary medicines of varied kinds are recommended for colds among a host of other complaints for which they are stated to possess curative powers. Apart, however, from such inclusive recommendations, a considerable number are put forward expressly and primarily for cold and catarrh, and it is a selection of these which is here described.

DR. LANE'S CATARRH CURE.

This is prepared and sold by a Company giving an address in London. The price is 1s. a bottle, containing 2½ fluid ounces.

Much printed matter is supplied with this preparation, and a few extracts are here given:

Catarrh, in its chronic form (and the complaints arising from it), is a malady which has not, up to the present time, received that attention and research from the medical faculty which it deserves. Most practitioners have given it merely a passing thought, or poohed at it as a mere cold which would soon pass off, and perhaps give some light tonic to tone up the stomach. And therein lies the fatal error, for Catarrh is a disease that cannot be trifled with, as millions can only too surely testify.

... to let any part or organ of the system become diseased breeds the seeds of a host of other complaints, as all the organs of the body are in sympathy with each other. The cause of this is easily explained in a case of Catarrh.... It invariably creates Biliousness, Constipation, Pleurisy, Asthma, Bronchitis, Catarrhal Fever, and Consumption.

It is estimated that over 20,000 people died in the United Kingdom last year of Consumption caused by Catarrh.

The speciality of myself and Associate Physicians is chronic disease in every form. Our library was selected to this end, and the Herbal World explored for this purpose—the successful treatment of chronic disease.

We have never seen one out of five hundred of the patients whom we have cured. Most cases can be treated just as well at a distance as if we saw them in person; as our experience enables us to judge correctly from a written description the nature and extent of the disease under which the patient is labouring.

The preparation is described on the wrapper as:

The _Only Reliable_ and Effective Preparation for the Permanent and _Radical Cure_ of this most dangerous disease.

The directions on the label are:

For Catarrh.—Pour one-half teaspoonful in the palm of the hand, close one nostril with the finger, and inhale the liquid through the open nostril with sufficient force to carry the spray down into the throat. Inhale another half teaspoonful through the other nostril in the same way; it is not advisable to swallow the Catarrh Cure—however, it is perfectly harmless if you chance to do so. Use night and morning and in extreme cases three times a day.

Analysis showed the composition of the liquid to be:

Phenol (carbolic acid) 0·4 part. Sodium chloride (common salt) 3.3 parts. Water to 100 fluid parts.

The traces of impurities usually present in common salt were also found.

The estimated cost of the ingredients in 2½ fluid ounces is one-thirtieth of a farthing.

VAN VLECK'S CATARRH BALM.

This balm is supplied by an American Company having an address in London. The price charged is 4s. 6d. for a package containing 1■ oz.

In an accompanying circular it is stated that:

This preparation is perfectly harmless, readily absorbed, and through its healing, soothing action affords immediate relief and quickly cures Catarrh of the Nose and Head, Catarrhal Deafness, Hay Fever, Cold in the Head, La Grippe, Tonsillitis, Sore Throat and all inflamed, irritated conditions of the nose and throat.

The “Balm” was an ointment, contained in a collapsible tube. The directions on the label are:

First clear your head out thoroughly by blowing your nose, then squeeze out from the tube a piece of Dr. Van Vleck’s Catarrh Balm about the size of a pea, on the end of the finger, and rub it well up into each nostril, hold the other nostril and snuff it up until you can feel it all the way up through the air passages in your head. For severe Catarrh in the Head and Cold in the Head also rub thoroughly over the outside of the nose and across the forehead and on the sides of the head just below the temples. For Catarrhal Sore Throat and Tonsillitis rub thoroughly on the outside of the throat and swallow at bedtime a small piece about the size of a pea. Do not get it into the eyes. This preparation is perfectly harmless, readily absorbed, and through its healing, antiseptic, soothing action affords immediate relief.

The substance consisted of soft paraffin containing a small quantity of phenol and about 2 per cent. of a mixture of volatile oils. Oils of eucalyptus, pumilio pine, and yellow sandal-wood were recognized, and the respective proportions of these were estimated by comparing mixtures of known composition with the original. The results obtained gave the following formula

Phenol 0·6 part. Sandal-wood oil 0·5 ” Oil of pumilio pine 0·7 ” ” eucalyptus 1.2 parts. Soft paraffin to 100

The estimated cost of the ingredients for 1■ oz. is ½d.

DR. MACKENZIE’S “ONE DAY” COLD CURE.

This is supplied by a Company described as of London and New York. The price charged for a box containing 30 tablets is 1s. 1½d.

This preparation is described on the package as:

The Best Cure! For the Worst Cold! A Speedy Cure in all Cases of Cold, Influenza, Headache, and all Neuralgic Affections. Nature’s Remedy.

Dose.—One tablet to be swallowed with a little water every two hours until relieved.

As a preventive, one every four hours.

Not for Children.

The tablets were coated with sugar coloured with ferric oxide (so-called chocolate coating); after removal of the coating they had an average weight of 2 grains. Analysis showed them to have the following composition:

Cinchonidine sulphate 0·83 grain. Acetanilide 0·71 ” Camphor 0·10 ” Talc 0·21 ” Water 0·15 ”

The estimated cost of the ingredients for 30 tablets is 1¼d.

KEENE’S “ONE NIGHT” COLD CURE.

This also is supplied by a Company giving its address as New York and London. The price charged is 1s. 1½d. a box, containing 30 tablets.

This is recommended in the circular enclosed in the box in the following terms:

Keene’s One Night Cold Cure will break up any cold overnight; or money refunded! Influenza cured in three days. Guarantee Label around every Box. If Keene’s One Night Cold Cure fails to Cure your Cold, your money will be cheerfully returned on presentation of Guarantee Label.

Keene’s One Night Cold Cure is in Tablet form and contains nothing injurious, being chiefly composed of Quinine, Cascara, Camphor, and other Ingredients adopted by the Leading Medical Authorities for Colds in the Head, Throat, and Lungs.

The “guarantee label” is worded as follows:

GUARANTEE.

If Keene’s “One Night” Cold Cure fails to effectually break up any ordinary cold, return this Guarantee with box to your Chemist and he will refund price paid.

Cascara—Bromide—Quinine—Ipecac— Camphor—Bryonia—tablets. 7½d. per box. The Keene Co. Irving A. Keene, Treasurer.

The tablets were coated with sugar, coloured with ferric oxide (so-called chocolate coating). After removal of the coating they had an average weight of 2·07 grains. Analysis showed that they contained no bromide, no quinine, except the minute trace occurring as an impurity in the cinchonine found, and no camphor in sufficient quantity to be detected; there was no evidence of any extract or other preparation of cascara, and if any were present, the quantity did not exceed a small trace; the alkaloid found did not give the slightest indication of ipecacuanha alkaloid; extract of bryonia may have been present, as it has no distinctive characters serving for identification. The ingredients found were:

Cinchonine sulphate 0·21 grain. (approx.). Acetanilide 0·32 ” ” Calcium carbonate 0·25 ” ” Starch 0·34 ” ” Extractive and excipient 0·87 ” ” In one tablet.

The extractive and excipient possessed no characters indicating the substance from which it was derived; it contained a small proportion of alkali in organic combination, equivalent to 1·2 per cent. of dried sodium carbonate in the tablet, and the mineral constituents usually present in vegetable extracts. The estimated cost of the ingredients for 30 tablets is ¼d.

MUNYON’S CATARRH TABLETS AND SPECIAL CATARRH CURE.

These two preparations, which have been at one time or another very extensively advertised, are supplied by a Homœopathic Company. They are stated to be manufactured in U.S. of America. The price charged for the tablets is 1s. a package, containing 17 tablets.

This preparation is recommended in the circular which accompanies it in the following terms:

CATARRH POSITIVELY CURED.—Are you a sufferer with catarrh? Have you taken all sorts of drugs and patent nostrums? Are you tired of paying big doctor bills without being cured? Are you willing to spend two shillings for a cure that permanently cures catarrh by removing the cause of the disease? If so, ask your chemist for a shilling bottle of Munyon’s Catarrh Cure and a shilling bottle of Catarrh Tablets. The Catarrh Cure will eradicate the disease from the system and the Tablets will cleanse and heal the afflicted parts and restore them to a natural and healthful condition.

On the package it is stated that:

When used in conjunction with the CATARRH CURE, they cure discharges from the head and throat, dryness, soreness and scabs in the nose, pains in the head, and all symptoms of Catarrh.

The directions are:

Dissolve one Tablet in 20 teaspoonfuls of warm water and use this solution for thorough cleansing of the nose and throat, night and morning. Inject through the nostrils with Munyon’s Atomizer or by snuffing.

The tablets had an average weight of 6 grains. Analysis showed the composition to be:

Sodium bicarbonate 1·87 grains. ” chloride 1·81 ” Borax, partly dehydrated 2·20 ” Phenol (carbolic acid) trace. Gum 0·12 grain.

in one tablet. The amount of borax was equivalent to 2·58 grains of the fully hydrated salt.

The estimated cost of the ingredients for 17 tablets is one-twentieth of a penny.

Besides the “Catarrh Cure” referred to in the above as intended for use with the tablets, there is a “Special Catarrh Cure” which costs 4s. a package containing 460 pilules.

On the package it is stated that:

It cures the most aggravated cases of hawking and spitting of mucus, stuffy or oppressed feeling in the head, dryness or scabs in the nose, gloomy, dull spirits, difficulty of breathing, dropping of mucus from the head into the throat, and liability to take cold easily.

The directions are:

Take four pellets every hour. Half quantity for children.

The average weight of the pilules was ½ grain. On first opening the bottle containing them a slight smell of alcohol was noticeable, but the loss of weight on drying was only 0·08 per cent. No medicament of any kind could be detected, nor any substance but sugar; determination of the amount of the latter showed 100 per cent. to be present.

From the odour of alcohol observed it is not unlikely that the pilules had been “medicated” by treatment with some dilute tincture, but if so, the amount of medicament so imparted was infinitesimal.

The estimated cost of 460 pilules is one-tenth of a penny.

BIRLEY’S ANTI-CATARRH.

The price charged for this fluid, sold by a London Company, is 1s. 1½d. a bottle, containing nearly 3 fluid ounces.

The bottle was accompanied by four pages of printed matter headed “The Birley Monthly Report,” in which the “Anti-Catarrh” was included in a “List and Prices of Dr. Birley’s Compounds of Free (or Unoxidised) Phosphorus,” and described as “Special Remedy for Catarrh and Influenza.” The following extracts are from the same circular, under the heading “The Wonders of Phosphorus.”

Free (or unoxidised) Phosphorus, whose chief seat or situation is in the brain, is one of the most important elements contained in our bodies. Without Free Phosphorus there can be no thought, and very probably no life....

One thing is proved beyond doubt, that the degree of intellectual thought depends upon the amount of Free Phosphorus in the brain, and just as the Phosphorus is unduly wasted, so does the brain power weaken....

Free Phosphorus, it is thus shown, must be the saving agent—no other means is possible. This one element must be replaced.

The directions are:

For an ordinary cold take one teaspoonful every two hours until better, then every third and fourth hour, and finally night and morning.

For severe attacks, commence by taking a dose every hour until better, then gradually increase the period between each dose as attack abates. For Children, give half doses.

Analysis showed the presence of:

Sugar (partly as “invert sugar”) 74 parts. Tartaric acid 1·15 parts. Phosphoric acid 0·07 part. Alcohol trace. Water to 100 fluid parts.

No free phosphorus could be detected, but the odour when the bottle was first opened suggested the presence of a trace. From the presence of a trace of alcohol it appears probable that an alcoholic solution of phosphorus had been added, and that the phosphoric acid had been formed by its oxidation. If the phosphorus found were in the free state each fluid drachm would contain about ¹/■■ grain. The liquid was of a light straw colour, probably produced by addition of a trace of colouring matter.

The estimated cost of the ingredients for 3 fluid ounces is ½d.

CHAPTER II.

COUGH MEDICINES

There are probably few, if any, ailments more frequently treated by the sufferer or his friends, without recourse to medical advice, than coughs and colds. The remedies employed in such domestic practice include preparations like “linseed tea” and others made at home, but these no doubt are supplemented in very many instances by some proprietary preparation, either one of those so

largely advertised, or the speciality of some local compounder. It might be contended that here, if anywhere, is a legitimate field for the maker of nostrums, and it is therefore of some interest to ascertain what is being supplied in such nostrums. The particulars as to composition and claims made which are given below show that they well illustrate the evils which inevitably creep into the dealing in secret remedies, and the downward steps which lead to purely swindling nostrums. One of the articles now described bears on the label the unusual recommendation, “For serious cases seek medical aid”; this preparation is recommended as a “valuable aid” in various complaints, and the fact that it contains morphine is stated clearly on the label, but information is not given as to the amount of morphine present. Less modest claims are made for competing articles, until we eventually reach such statements as “all that is necessary is to take one dose of the lung tonic in warm water on retiring to rest, and the cold will have disappeared in the morning ... cure is quite certain,” and “If it fails no other medicine will ever succeed.” Again, while the presence of morphine in one of the medicines is plainly declared, as we have stated, this is not so in other instances. In one of those in which on analysis morphine was found to be present the advertisement begins with a “guarantee” that the medicinal remedies contained in the lozenges cannot injure the most delicate constitution, and includes the statement that they may be safely administered to very young children; in another case the specific declaration is made that “the cough pills do not contain opium,” which would certainly be regarded by most people as meaning that they do not contain the active principle of opium—morphine; and yet this was found to be present. The uncertainty as to what the composition of a secret medicine may be at any particular time is illustrated by another of the articles described, which has in past years been the subject of legal proceedings in the course of which the presence of morphine was proved, but which is now found not to contain any.

The number of advertised proprietary medicines for the cure of coughs is very large, and the number of those but little advertised and having principally a local sale is still larger; the latter, as a rule, have a good deal of resemblance to the advertised preparations. A selected few of the most widely advertised of this class have been examined.

The information which chemical analysis can give as to the composition of proprietary medicines is necessarily limited to the recognition of those ingredients which possess more or less definite chemical properties. The makers, of course, can make use of any one or more of a long series of vegetable extracts which very much resemble each other, and of various sweetening and flavouring materials sold for the purpose. In the case of many secret preparations analysis can afford complete and positive information as to their composition; but this is not so in every case, owing to many preparations commonly used in pharmacy being devoid of definite active principles that can be identified, and possessing no characters distinguishing them from others of the same class. Many such preparations are likely to be employed in cough mixtures; and, as these medicines usually contain a large proportion of treacle, honey, extract of liquorice, decoction of linseed, or some other old-fashioned complex preparations as basis, the identification of small proportions of many substances which are likely to be present becomes practically impossible. Many of the drugs in recognised use for coughs, such as senega, Virginian prune, etc., as well as domestic remedies like horehound and coltsfoot, are practically safe from certain identification by chemical analysis for such reasons, and in some of the preparations described below such substances may perhaps be present in addition to the ingredients named. The receipts given are not put forward as necessarily representing the whole of the ingredients in the articles in question, but they probably include all those which are of any importance or possess any known curative action.

The chief interest in the composition of such medicines, however, centres in the presence or absence of more potent remedies, such as preparations of opium, ipecacuanha, etc.; and here the analyst is on surer ground. The extraction of minute quantities of alkaloids from complex mixtures containing large quantities of saccharine and “extractive” matters is, however, a matter of much difficulty, and their identification is complicated by the great similarity in the behaviour of morphine and the alkaloids of ipecacuanha towards the various reagents used in their recognition. In this connection it may be pointed out that one or two of the nostrums here dealt with have been the subject of fairly frequent legal proceedings in consequence of their having been sold without proper observance of the poisons regulations, and the evidence given in such cases has shown wide differences in the results obtained by different analysts of high standing, both as to the quantity of morphine present, and even as to the fact of its presence or absence. In making the analyses here recorded, great pains have been taken to obtain accurate results, and they have been confirmed by the employment of alternative methods, etc.; but the results can only be given subject to the caution just expressed.

KAY’S LINSEED COMPOUND.

This compound is sold by an English provincial company in bottles, price, 9½d., 1s. 1½d., 2s. 9d., 4s. 6d., and 11s. per bottle; the 2s. 9d. size contained a little over 5½ fluid ounces.

This preparation is described on the label, wrapper, and in circulars, both as “Linseed Compound,” which is given as the registered trade mark, and as “Kay’s Compound Essence of Linseed, Aniseed, Senega, Squill, Tolu, etc.” On the label it is also stated that it

contains a preparation of chloroform and morphine, and it is, therefore, labelled Poison. It is Demulcent, Expectorant, Tonic, and Soothing for Colds, Coughs, Asthma, Hoarseness, Difficulty of Breathing, Consumption, and Simple Ailments of the Chest, Throat, and Lungs.

In a pamphlet enclosed in the package, this preparation is recommended to be taken for Cold, Influenza, Sore Throat and Quinsey, Pulmonary Catarrh, Bronchitis, Asthma, Consumption of the Lungs, Whooping Cough and Croup. In most of these, however, it is recommended as a “valuable aid” rather than a positive cure; other articles, such as ipecacuanha wine, muriate of ammonia, cod liver oil, and chemical food, as well as “Kay’s Linum Catharticum Pills,” are also recommended; while under Bronchitis we read:

In an acute attack, _i.e._, when the symptoms are inflammatory with much fever, etc., _the family doctor should at once be called in_.

The directions on the label are as follows:

Scale of Doses { To be modified according to the { age or debility of the Patient.

For over 21 years, a teaspoonful in water, at bedtime. ” 12 ” half a teaspoonful ” ” ” 6 ” 15 drops ” ” ” 4 ” 10 ” ” ” ” 2 ” 5 ” ” ”

Half Doses may be taken three or four times a day. It is not intended for Infants. For serious cases seek medical aid.

Analysis showed that 100 parts by measure contained 1·07 parts of chloroform and 4·3 parts of alcohol, both by measure, and 67 parts of solids; about 48 parts of the latter consisted of sugar, partly in the form of invert sugar, and the remaining 19 parts consisted principally of the mucilage of decoction of linseed; oil of aniseed was present, and evidence was obtained of small quantities of preparations of tolu and squill. Tho ipecacuanha alkaloids extracted amounted to 0·007 per cent., and the morphine to 0·021 per cent. If the ipecacuanha were present in the form of wine of the official strength, this represents:

Ipecacuanha wine 42 minims. Morphine ¹/■ grain. Chloroform 5 minims.

in each fluid ounce.

OWBRIDGE’S LUNG TONIC.

This is sold by another English provincial company, price, 1s. 1½d., 2s. 9d., 4s. 6d., and 11s. a bottle; the 2s. 9d. size contained a little over 6½ fluid ounces.

It is stated on the wrapper that this:

Cures Coughs, Colds, Asthma, Bronchitis, Influenza, and all Affections of the Chest, Throat, and Lungs.

Also,

This Preparation does not contain any Opium, Laudanum, or Morphine, therefore does not require a Poison Label.

A pamphlet was enclosed in the package, from which the following is an extract:

Having once contracted a cold, however slight, it is of the first importance to have it thoroughly and radically removed. To do this it is worse than useless to rely upon a few lozenges, or any of the simple expedients to which many have recourse. Avoid linseed poultices, which are excessively weakening, and highly calculated to make the patient liable to a second, and, perhaps, more severe cold than the first. All that is necessary is to take one dose of the lung tonic in warm water on retiring to rest, and the cold will have disappeared in the morning. The lungs and bronchial tubes will be fortified and invigorated to an extraordinary degree. Should the cough not be quite removed by the first dose, continue according to directions. Cure is quite certain.

The directions on the label were:

Scale of Doses.

Above 14 years one teaspoonful. 6 to 14 years half a teaspoonful. 3 ” 6 ” fifteen drops. 1 ” 3 ” five to seven drops. 6 months to 1 year three to five drops.

Not to be given to a child under Six Months old.

To be repeated 3 or 4 times a day, if necessary. The doses given during the day should be mixed with a little cold water, the one at bedtime in a tablespoonful of warm water.

Analysis showed that 100 parts by measure contained 0·3 part of chloroform and 2 parts of alcohol, both by measure, and 89 parts of solids; about 73 parts of the latter consisted of sugar, rather more than half of which was in the form of invert sugar; it is probable that this had been added in the form of honey, and that the remainder of the solids consisted largely of the non-saccharine portion of the honey. Oils of aniseed and peppermint were present, and evidence was obtained of a very small quantity of a preparation of capsicum. The alkaloids of ipecacuanha were found to the amount of 0·002 per cent.; if these were present in the form of wine of the official strength, this represents:

Ipecacuanha wine 15 minims. Chloroform 2 ”

in each fluid ounce.

POWELL’S BALSAM OF ANISEED.

This fluid, prepared by a London maker, is sold in bottles, price, 1s. 1½d., 2s. 3d., 4s. 6d., and 11s. per bottle; the 2s. 3d. size contained a little over 3 fluid ounces.

In a circular enclosed with the bottle it was stated that:

This old and invaluable Medicine has the extraordinary property of immediately relieving Coughs, Colds, Bronchitis, Hoarseness, Difficulty of Breathing, and Huskiness in the Throat. It operates by dissolving the congealed Phlegm, and thus promotes free expectoration....

In Asthma, Chronic Cough, Influenza, Difficulty of Breathing, etc., no pen can describe the wonders that have been wrought by this deservedly popular preparation.

The directions for use were:

For a Grown Person a teaspoonful two or three times a day. For a child about 8 years old, 20 drops; and 12 years, 40 drops.

N.B.—Grown persons as well as children should take it in a little gruel or warm water; or saturate a lump of sugar with the above quantities is a pleasant way of taking it.

Analysis showed that 100 parts by measure contained 1·8 parts of benzoic acid, about 4·2 parts of extract of liquorice, and 2 parts of sugar, 40 parts by volume of alcohol, and enough oil of aniseed to give a strong aniseed flavour; a very small quantity of an aromatic resin, apparently benzoin, was also found, and 0·012 per cent. of alkaloid. This alkaloid resembled morphine in its behaviour to solvents, by which all the commoner alkaloids were excluded; but other tests showed that it was not morphine, and it is possible that it was a morphine derivative, such as dionine or peronine, but it was not found practicable to establish its exact identity owing to the smallness of the amount. Powell’s Balsam of Aniseed has, in the past, been the subject of legal proceedings on several occasions, and evidence has been brought in those proceedings proving that it contained morphine; so that it would seem that its composition has been changed since then.

DR. KILMER’S INDIAN COUGH CURE.

This preparation, stated to be made in U.S.A., is advertised from an address in London. The price is 1s. 1½d. a bottle, containing 3 fluid ounces.

It was stated on the outside of the package that:

This wonderful preparation contains no opium, morphine, chloral, or other hurtful drugs, and therefore does not dry up a cough. Every ingredient is from Vegetable products which grow within sight of almost every sufferer. It will not only help but cure the most Chronic and Complicated cases.

The directions were:

Dose: ½, 1, or 2 teaspoonfuls every ½, 1, 2, 3, or 4 hours as the case may require. Children—less according to age.

Analysis showed that 100 parts contained 63 parts of solids, of which practically the whole was sugar; there was also present about 2 per cent. of alcohol and about 0·5 per cent. of oil of pumilio pine, with rather less than 0·1 per cent. of a resinous substance agreeing well with the resins from compound tincture of benzoin; a small resinous deposit also remained adhering to the inside of the bottle. A trace of a bitter yellowish substance was present, which may have been the aloes contained in the compound tincture, but did not agree perfectly with it in character; the quantity was too minute for exact identification. No alkaloid was present.

CROSBY'S BALSAMIC COUGH ELIXIR.

This elixir, sold from a provincial English town, and wholesale through a company in London, costs 1s. 1½d., 2s. 9d., and 4s. 6d. per bottle; the 2s. 9d. size contained nearly 4¾ ounces.

It was described on the label as:

A safe, speedy, and effectual remedy for Coughs, Colds, Hoarseness, Difficulty of Breathing, Wheezing and Irritation of the Throat, Hooping Cough, Asthma, and Incipient Consumption.

In circulars enclosed with the bottle, its use in these various complaints was more fully described; and it was stated further that:—

It contains no opiates, and is absolutely non-poisonous, and may therefore be taken with safety by the young and aged alike.

The directions given on the label were:

For Children, one month to one year, 5 to 10 drops in a little water. From one to five years, 10 to 20 drops. From five to ten years, 20 to 30 drops. From ten to fifteen years, 30 drops to one teaspoonful. From fifteen years and upwards, one teaspoonful, gradually increased to three teaspoonfuls, in a wineglassful of water.

Analysis showed that 100 parts by measure contained 65 parts of solid matter, about 58 parts of which consisted of invert sugar, 10·6 parts by volume of alcohol, a trace of chloroform, 1·35 parts of sulphuric acid, and 0·3 part of acetic acid; a trace of an aromatic substance probably derived from tolu was present, and a minute trace of alkaloid (much less than 0·001 per cent.); the remainder appeared to consist of extractive and colouring matter, and may have contained the non-saccharine portion of honey if the invert sugar were added in that form. A trace of acetic ether could be detected, and it is probable that the acetic acid found represented acetic ether originally added, which had undergone hydrolysis; in that case the amount of acetic ether originally present would be 2¼ minims in 1 fluid ounce. The sulphuric acid found corresponds to 44 minims of the official dilute sulphuric acid in 1 fluid ounce.

VENO'S LIGHTNING COUGH CURE.

This is prepared by a company in an English manufacturing town. The price charged is 1s. 1½d. a bottle, containing 2¾ fluid ounces.

On the label it was stated that:

If it fails no other medicine will ever succeed. It should be used in all cases of Coughs, Colds, Bronchitis, Pleurisy, Sore Throat, Hoarseness, Asthma, Croup, Whooping Cough, Influenza, and Catarrh.

In most cases it should be used with Veno's Lightning Fluid.

Dose.—For an Adult, one teaspoonful; for a Child under ten, half teaspoonful; for an Infant, five or ten drops every two or three hours, during the day only.

Analysis showed that 100 parts by measure contained 7·6 parts of glycerine, 1·6 parts by volume of alcohol, a trace of chloroform, 0·23 part of a resin, 0·2 part of alkaline ash, and 1·1 parts of extractive and colouring matter. No alkaloid was present. The resin was not aromatic, and possessed no well-marked characters, but showed some resemblance to the resin of _Grindelia robusta_; the fluid extract of this drug is prepared with the aid of alkali, and the strongly alkaline nature of the ash found would agree with the presence of fluid extract of grindelia, but positive proof of the presence of the latter could not be obtained; the amount of resin found corresponds to about 7 minims of the fluid extract in 1 fluid ounce.

KEATING’S COUGH LOZENGES.

These lozenges are sold from an address in London in boxes, price, 1s. 1½d., 2s. 9d., 4s. 6d., and 11s. per box; the 1s. 1½d. size contained 50 lozenges.

A circular enclosed in the package was headed:

Notice—Guarantee.

The medicinal remedies contained in these lozenges cannot injure the most delicate constitution.

Another extract from the circular stated:

Very many also of the Nobility and Clergy, and of the public generally use them _under the recommendation of some of the most eminent of the Faculty_. Such medical testimony must be convincing of their efficacy as well as conveying the satisfactory assurance of their freedom from any medicine in the slightest degree injurious to the constitution, Medical Men being well aware of the deleterious effects of many preparations, which in Pulmonary Affections do but mask the symptoms for a time, and afford only temporary relief, while perhaps the constitutional disease is aggravated, or at least unsubdued. They may be safely administered to females of the most delicate frame, and to very young children, for they not only allay Cough and Nervous Irritation, but they sustain the constitution, by promoting a healthy state of the Digestive Organs. They have immediate influence over the following cases:—_Asthmatic and Consumptive Complaints, Coughs, Shortness of Breath, Hoarseness, etc., etc._

Directions for Use. One or two, taken at bedtime, will allay the irritation in the Throat, and prevent the Cough from disturbing the patient during the night, _and one also eight or ten times in the day_, when the Cough is troublesome, will afford great relief.

The average weight of the lozenges was 16½ grains; analysis showed that they contained morphine, alkaloids of ipecacuanha, extract of liquorice, sugar (partly as invert sugar), and gum; some evidence was also obtained of the presence of extract of squill and tolu, but positive proof of the identity of these was not obtainable. The proportions of the various ingredients found corresponded to:

Morphine 0·007 grain. Ipecacuanha 0·07 ” Extract of liquorice 2·1 grains. Sugars 13 ”

in one lozenge.

BEECHAM’S COUGH PILLS.

These cough pills, sold from a town in Lancashire, cost 1s. 1½d. per box, containing 56 pills.

The following extracts are from a circular enclosed with the box:

Persons suffering from Cough and kindred troubles should relieve their minds of the idea that nothing will benefit them unless it be in the form of a lozenge, or taken as liquid. Let them try _Beecham’s Cough Pills_, and they will never regret it.

The _Cough Pills_ do not contain opium; they do not constipate; they do not upset the stomach. On the first symptoms of a Cold or Chill, a timely dose of Beecham’s Cough Pills will invariably ward off all dangerous features. For years many families have used no other Winter Medicine. Householders and travellers should avail themselves of this good, safe, and simple remedy for Coughs in general, Asthma, Bronchial Affections, Hoarseness, Shortness of Breath, Tightness and Oppression of the Chest, Wheezing, etc.

The doses may be from three to six pills morning, noon, and night.

The pills had an average weight of 1·4 grains. In spite of the statement that they “do not contain opium,” analysis showed morphine to be present, together with powdered squill, powdered aniseed, extract of liquorice, and a resinous substance agreeing in character with the resin of ammoniacum. Approximate determination of the proportions of the ingredients is alone possible in such a mixture; the results obtained pointed to the following formula:

Morphine 0·0035 grain. Powdered squill 0·1 ” Powdered aniseed 0·3 ” Ammoniacum 0·3 ” Extract of liquorice 0·4 ”

in one pill.

SOME GERMAN NOSTRUMS.

Dr. F. Zernik, assistant in the Pharmaceutical Institute of the University of Berlin, undertook a short time ago, at the invitation of the Editor of the _Deutsche Medicinische Wochenschrift_, to report on some of the secret remedies which are thrown on the market in such numbers in Germany as well as England. It would appear that for the most part the remedies advertised in Germany are not the same as those most advertised in this country, but it is proposed in this and subsequent chapters to give some abstracts from the articles in which Dr. Zernik has from time to time reported the results of his examinations.

DR. LAUSER'S COUGH DROPS.

Dr. Zernik found on analysis that these Cough Drops did not contain the ingredients alleged; there was for instance only 3·35 per cent. of alcohol, although the advertiser speaks of tinctures of 50 per cent. In addition to this small proportion of alcohol the mixture appeared to consist of a watery solution of liquorice, an infusion of senna root, some ammoniated solution of aniseed and small quantities of ammonium chloride.

REICHEL'S COUGH DROPS.

Reichel's Cough Drops cost 1 mark for a bottle containing 65 ccm., about 2¼ fluid ounces. The purchaser is supposed to take 15 or 20 drops on sugar or in water four or five times a day. It is an alcoholic fluid, smelling and tasting of arnica, pimpinella, and anise.

TUSSOTHYM.

Tussothym, in spite of the wonderful qualities claimed for it by the firm producing it, proved to be a weak alcoholic distillate of thyme, diluted with water but probably containing another indifferent drug. It is advertised as good for all diseases of the respiratory organs, and especially for whooping cough.

DR. B. ASSMANN'S WHOOPING COUGH REMEDY.

This Whooping Cough Remedy is, according to the vendor, so complicated that it is only made by himself, and cannot be obtained elsewhere. The packet contains forty powders, twenty of which are marked No. 1, and twenty No. 2. The chemical analysis showed that each powder, weighing 2 grams, consisted of milk sugar (lactose). No other constituent was detected.

CHAPTER III.

CONSUMPTION CURES.

Nostrums and quack medicines vary greatly in the extent to which they constitute deliberate fraud. In the case of some of them, it is easy to believe that the makers themselves have a certain faith in their preparations, and recommend them in cases for which they are unsuited with that bona fides which arises from ignorance, assisted, unconsciously perhaps, by an appreciation of the profitable nature of the business. Such preparations frequently contain some one or more of the drugs in common use for the complaints for which the nostrum is offered, and are even, occasionally, combinations compounded in the first place from a medical prescription which may have been found useful in certain appropriate cases. The injury to the public in such instances arises from the excessive nature of the claims made, the excessive price usually charged, and the probability of the advertised medicine being taken in cases for which it is quite unsuitable, when it may do harm positively by its effects or negatively by preventing the sufferer from seeking proper advice.

But with other proprietary medicines it is quite clear that the makers cannot in the slightest degree believe in the claims they make; the "remedy" in these cases is some substance or mixture devoid of medicinal activity, or possessing some slight therapeutic property having no relation to the disease for which the nostrum is put forward as a cure. It is often, indeed, for inert preparations that the most extravagant and emphatic claims are made; the makers, and the advertisement-writers whom they employ, are untrammelled by any necessity of squaring their statements with the real properties of the thing to be recommended, and having set out consciously and deliberately to deceive, they are able to give their whole attention to telling the most effective stories in the most plausible manner, and reaping the maximum of payment for the minimum of expenditure. People who are ill or suffering are to be frightened with impressive pictures of the aggravated suffering and premature death that await them unless they take the "only cure" in question, therefore let them be frightened thoroughly. Careful suggestion will induce people who are not ill to believe that they or some of those dear to them are in the early stages of some disease; therefore let everything possible in the way of striking advertisements, personal letters, and repeated assertions be utilised to produce the result. It is the victim's money that is wanted;

therefore let the price be fixed high, and the advertisements be written up to it. If it should be discovered by correspondence that so much cannot be cajoled or frightened out of an individual sufferer, the price can be reduced gradually as “special concessions,” in return for which testimonials may be extracted.

Of quack medicines the sale of which is conducted more or less on these fines, two examples are described in this chapter, and other examples will be enumerated later.

One of the two now dealt with is “Tuberculozyne,” largely advertised in Great Britain but apparently of American origin; it affords an instructive example of the methods of the Transatlantic nostrum monger. The two liquids sold under this name consist of little more than coloured, flavoured water, but the modest price demanded is £2 10s. for a month’s, supply. No effort is spared to induce the victim to continue the “treatment” month by month, in spite of the evident absence of any benefit, which is unblushingly accounted for by the seriousness of the particular case, while the necessity of getting the system thoroughly permeated with the remedy is insisted on. The sale of another preparation advertised as a cure for consumption, Stevens’ Consumption Cure, is conducted in a very similar way, but this time the herbs are said to be African, and the odd names they bear certainly have a Kaffir flavour. The vendor considerately warns the public against American quacks and impostors and against the preposterous and wicked swindles of Polish or German Jews. Although Stevens is so engagingly candid about his rivals he follows the plan of sending one letter after another to any sufferer whose name he may have obtained, a system which seems to have been invented in America; it is certainly cheaper than bold advertisement in newspapers, and is apparently found even more satisfactory, as it enables the vendor to give individual attention to the depth of his correspondent’s pocket if not to the severity of his disease. But Stevens has somewhat bettered his instruction, and his letters and circulars have a character of their own due to the effrontery of his attitude toward the medical profession. Persons who respond to the advertisement receive a list of questions to be answered by the doctor who has attended them, and are advised to continue under the observation of their medical man in order that the latter may be impressed by the marvellous effects of the remedy. Not long ago a circular letter was sent out to medical practitioners, asking them to treat consumptive cases “which defy all the ordinary remedies” with this secret preparation. The circular continues: “The great drawback to my cure, so far as the medical profession is concerned, has always been the fact that I would not reveal its formula. This is now done away with; its formula is 80 grains of umckaloabo root and 13■ grains of chijitse to every ounce, prepared according to _British Pharmacopœia_ methods.” The farce of revealing a formula by the employment of such fancy names as these is one of the oldest dodges of the quack medicine man, and no such names as “umckaloabo” and “chijitse” appear in any available work of reference on pharmacy. Enquiries made in various parts of South Africa have been negative, experts in native matters being unable to ascertain that the names were known. Further, the Native Affairs Department of Cape Colony has caused enquiries to be made in the Transkeian territories into the question whether the native tribes there resident had any knowledge of “umckaloabo” and “chijitse,” or of their reputed medicinal properties. The result of the inquiry was entirely negative. Nothing was known of any such plants, nor was it even possible to identify their names. Smith’s _South African Materia Medica_ contains no record of any such names as “umckaloabo” and “chijitse.”

A similar system of repeated letters sent in series to the sufferer or his friends appears to be followed by the Weidhaas Hygienic Institute, Ltd., which carries on a home in the south of England but also treats patients by correspondence. The proprietors, who would seem to hail from Germany, issue a pamphlet with the title _Dum spiro spero_, which is made up mainly of the usual testimonials, but contains also a sort of outline of the physiology of various organs, taken from medical works. The pamphlet does not differ from the ordinary productions of advertising quacks; the terms are said to be very moderate, the more so as it is the rule to make one charge only for the whole treatment, the proprietors taking the risk of its being of long duration. It would seem, however, that this arrangement is not always followed, for in a “Diet Table” headed “Direction for Weidhaas Home Treatment” we find the following:

It is absolutely necessary that all patients, while under my treatment, shall take the “Star Tonic” regularly.

On Rising.—Take one cup of “Star Tonic.” (This must be always taken in sips only.)

For Breakfast.—Take the delicately flavoured Nutritive Salts Cocoa, boiled in milk (which, being specially prepared for invalids, on account of the great percentage of nutritive salts which no other cocoa contains, is most suitable in your case....)

Between Breakfast and Lunch take one or two tumblers of milk. If possible this should always be taken in the form of Kefyr, one of the easiest digestible nourishing and strengthening tonics. (Full particulars of this are enclosed herewith.)...

Half an hour before mid-day meal.—(From 1 to 2 o’clock.) Sip one cup of Star Tonic.

For Mid-day Meal.—_Make it a strict rule to take regularly green vegetables of some kind, such as spinach, cabbage, lettuce, etc. A fair amount of these should be taken daily._ To these may be added a few potatoes, very little meat or fish, and now and then, in the place of the latter, some pulses, such as lentils (German are best)....

At Tea Time.—If absolutely necessary, take a cup of weak ordinary tea or health coffee; better still, take a cup of Star Tonic, some _cold_ toast....

For Supper.—(Let this meal be not later than two-and-a-half, or, better still, three hours before going to bed.) Take either Cocoa or Kefyr....

Before going to bed.—Always make a point of taking one glass of Kefyr or cup of Star Tonic.

When in bed always have some cold “Star Tonic” near at hand, and sip some when troubled with cough or acute symptoms.

At the bottom of the diet table is a notice to the following effect:

“The above specially recommended articles can be had from the Sales’ Department of the Weidhaas Hygienic Institute, Ltd.”

In the circular, referred to above as enclosed, Kefyr ferment is offered for sale.

In one case which was enquired into of a young man who had been induced to obtain the treatment, his mother wrote to the institute complaining that the treatment appeared to have done her son more harm than good. The reply, after insisting that the remedy supplied was the very best cure for his complaint, continued: “As to it lowering his vitality, let me say that it is not unusual for patients to feel apparently worse in the beginning, but it only shows that the treatment is disturbing the cause of the trouble. Now, this is just what I want it to do. I want to disturb it and thus drive it out of the system. I hope then you will allow your son to proceed under my directions. Give the treatment a fair trial and it will do all that is claimed for it.” The patient was at the time in an advanced stage of pulmonary phthisis, and died of hæmoptysis, of which he had had two previous attacks, seven weeks after the letter quoted above was written. A month after his death a letter was addressed to him by the director of the institute in the course of which it was stated that: “Many patients do not gain immediate relief, or even partial improvement during the early stages of the treatment, but Perseverance and a faithful adherence to all my instructions will invariably bring about the desired result.”

Among the papers sent to an enquirer was a printed form which seems worthy of reproduction, since it illustrates a method of getting into touch with possible patients, which appears to be followed with variations by other companies that appeal to the sick:

R. B.

HAVE YOU FRIENDS WHO NEED OUR TREATMENT?

If you know of anyone whom you think might derive benefit from the use of our Home Treatment, you will do them and us a great favour by noting hereon their names, addresses, and the trouble you believe them to be afflicted with. Upon receipt of the names we will send them information concerning our method of treatment, _but will not mention your name unless you desire it_.

----------+----------+---------- Name. | Address. | Ailment.
----------+----------+---------- | | | | | | | | | | ----------+----------+---------- Please return to The Weidhaas Hygienic Institute.

Some time ago a firm of pharmaceutical chemists in a provincial town received a postcard from a company which offered 5s. for the name of any patient suffering from diabetes, pointing out that “it is money easily earned.” The pharmaceutical chemists expressed indignation at the attempt to bribe them to commit a breach of confidence, but such a request might not be so regarded by a patient, more especially if the advertiser lays great stress upon his benevolent motives, and his anxiety to benefit as many persons as possible.

But although this letter-writing system with its paraphernalia of biographies of the discoverer, typewritten personal letters, free coupons and guarantee bonds is much in vogue, there are other nostrums advertised in the old-fashioned way and sold at the familiar price of 1s. 1½d. for a small bottle. Among these are some old preparations for coughs, for which more emphatic claims as remedies for consumption have been made of late years. The result of the analysis of two of these will first be given.

CONGREVE’S BALSAMIC ELIXIR.

This preparation, advertised from an address in London, is sold in bottles, price 1s. 1½d., 2s. 9d., 4s. 6d., 11s., and 22s. The 2s. 9d. bottle contained 1■ fluid ounces, the 4s. 6d. bottle contained 4 fluid ounces.

On the outer package was to be read:

Congreve's Balsamic Elixir. Has had a World-wide Reputation for 80 years as the Best Remedy for Consumption, also for Asthma, Chronic Bronchitis, Coughs, Colds, and Whooping cough. Safe and Effective. Free from any poison.

The following extracts are from a circular enclosed with the bottle:

In the most obstinate attacks of Asthma, which have threatened speedy suffocation, when the sufferer, harassed by excessive coughing, has laboured dreadfully for breath, with an acuteness of agony not to be described, this Balsam has restored the patient to health, after the medical practitioner had abandoned the usual means in despair.

In Pulmonary Consumption, the best remedy is this Balsamic Elixir, as most unquestionable Testimonials prove. It has been successfully prescribed in Consumptive cases regarded as hopeless by the first physicians.

Correspondence. Advice by letter from time to time will be given to any patient whilst continuing Mr. Congreve's Treatment, provided that the 22s. or 11s. bottles of Elixir are _obtained direct from_ [the address given by the vendor in his advertisements] during the period of correspondence.

The directions were:

For adults.—Take a teaspoonful, alone or mixed with honey or lump sugar, three or four times a day, as the urgency of the case requires. Children from 8 to 15 years may take two-thirds of a teaspoonful; from 5 to 8 years, half a teaspoonful; from 2 to 5 years, twenty drops; at six months, ten drops; younger infants from four to six drops.

The "elixir" was a bright red liquid; analysis showed it to contain 28·5 per cent. by volume of alcohol, and 2·6 per cent. of total solids; the latter consisted of resinous constituents (about 0·5 per cent.), sugar (about 1 per cent.), a little tannin, colouring matter (apparently cochineal), and extractive. Alkaloid was present only to the extent of a trace, under 0·001 per cent.; the extractive showed no characters by which its source could be determined; the resinous material was of an aromatic nature similar to the resins of benzoin, storax, tolu, or balsam of Peru, and appeared to be derived from a mixture of two or more of these. No other active ingredients were found to be present.

THE BROMPTON CONSUMPTION AND COUGH SPECIFIC.

The "Sole proprietor" gives an address in a part of London remote from Brompton, but it is perhaps hoped that the name may suggest some connection with the well-known Brompton Consumption Hospital. The price charged is 1s. 1½d., 2s. 9d., 4s. 6d., and 11s. per bottle; the 2s. 9d. bottle contained 3■ fluid ounces.

The origin of the preparation is thus described:

This Specific is prepared from the Prescription of an eminent Physician, who practised nearly forty years in Madeira, he was celebrated for his success in the treatment of Consumption and diseases of the Chest. Upon a visit to this country some years since, he gave the Prescription to a late Physician, who tried it upon five hundred out-patients; its effect was wonderful; it acted like magic upon their Coughs, and prevented that great waste of strength and flesh peculiar to this disease. It will save the lives of thousands and prevent Consumption, by administering it upon the first symptoms of Cough, which will be immediately cured by a few doses.

In a circular enclosed with the bottle it was stated:

A Cough is the forerunner of Consumption. In England alone 50,000 people die of it thus constituting one-fourth of the nation's death rate annually. It has destroyed more human beings than War, Pestilence, and Famine combined; it neither spares the old nor young, "and there is no family in which this rapacious destroyer of the human race has not had its victim." It is a well-known fact that people with diseased lungs can live for years, and follow their usual avocations in life, provided they are relieved of the principal feature of the disease—the Cough—which shakes and destroys the very elements of the blood, upon which life is supported. How very valuable and important to all, then, must a medicine be which will arrest and cure so fearful a malady!

The directions were:

Dose.—One teaspoonful three times a day and at bedtime. It may be repeated at night, or at any time when the Cough is troublesome.—Children over five years of age, one-third of a teaspoonful.

The following appeared on the outside wrapper:

In conformity with the Sale of Poisons Act, 1868, this preparation, containing a minute quantity of Laudanum and Chloroform, must be labelled Poison, but its composition remains unaltered.

The preparation was a syrupy liquid of pleasant odour and taste, resembling diluted treacle. Analysis showed it to contain in 100 fluid parts, 61·4 parts of total solids; of this, 35·5 parts were glucose and 9·9 parts cane sugar, and 2·6 parts ash, consisting principally of calcium sulphate. Chloroform, referred to on the wrapper, was not present in sufficient traces to be detected; alkaloid was present to the extent of 0·025 part in 100 fluid parts, of which 0·015 part appeared to consist of the alkaloids of ipecacuanha, and approximately 0·01 part was morphine. The difference between the sugars found and the total solids would be fully accounted for by the non-saccharine portion of treacle; extractive contained in the preparations of ipecacuanha and opium used would also be included in this. Small proportions of other drugs having no well-marked characters might possibly also be present; there was no evidence of any further ingredients, but in the presence of so large a proportion of treacle small quantities of indifferent substances it would not be possible to detect.

About 1 per cent. by volume of alcohol was present; assuming liquid extract of ipecacuanha and tincture of opium to have been the preparations of these drugs used, the formula is approximately:

Liquid extract of ipecacuanha 0·75 part. Tincture of opium 1·3 parts. Treacle 75 parts. Water to 100 fluid parts.

Estimated cost of ingredients for 3■ fluid ounces, ¾d.

STEVENS' CONSUMPTION CURE.

This is advertised as manufactured only by C. H. Stevens. The price is 5s. per bottle, containing 2¼ fluid ounces.

This preparation does not appear now to go under any other name than that of "Stevens' Consumption Cure"; as regards its past history, the following extract from _Truth_ Cautionary List for 1908 is of interest:

Stevens, C. H.—The proprietor of a remedy for consumption which has been put on the market in South Africa and England under the name of Sacco, and later in South Africa as Lungsava, the recipe for which is stated to have been long in use amongst the Kaffirs and Zulus. In connection with the advertising of Sacco in England, an article which appeared in _Truth_ was circulated in a mutilated form, omitting a condemnation of its sale as an absolute remedy for consumption. Stevens has acquired a number of testimonials from medical men, who must now regret their precipitate action. He is now in England on a new campaign.

The claims made for this preparation were put forward in printed circulars, and in letters, apparently printed in imitation of typewriting, sent at intervals to an applicant for particulars of the cure. Extracts from these are here given:

It has been admitted the world over that there is no remedy known to the Medical Fraternity to really cure Consumption, so it is preposterous to claim the ordinary drugs that are known to every Chemist even, to cure this disease, just because they are given a fancy name, and advertised by a Polish or a German Jew; it is not only preposterous but a wicked swindle.

There is no other treatment, drug, or medicine advertised in Great Britain to-day to cure Consumption, the ingredients of which are not known to every doctor and chemist in the world, and if you cannot obtain relief from these under the care of your own Medical Adviser, how can you be cured by using them on the advice of an American Quack.

Your own doctor will bear out what I say. Most of these American Impostors come to England after the U.S.A. Post Office Authorities have refused to convey their letters.

I do not say in my advertisements "Consumption can be cured," "Consumption is curable," or any such evasive remarks, but I say "_I will guarantee to cure you_ if you are consumptive, or _return your money_ in full," and that my terms are "No Cure, No Pay."

The African herbs which my Cure is prepared from have never been used by any white Doctor or Chemist before I introduced same to civilization a few years ago. These herbs are original and have defied our cleverest Analysts to discover the active principals they

contain....

I only returned to England a few weeks ago to prove my Cure to the satisfaction of the British Government, having been absent for many years....

It does not matter whether a Doctor is attending patients or not whilst they are under my treatment, although I always prefer a Doctor to be in attendance to see the cure being effected because I particularly wish to convince the Medical fraternity of the genuineness of my cure.

From the first letter:

Usually two or three weeks' treatment is quite sufficient to make a substantial improvement, and a three months' course, in most cases, is sufficient to effect a cure.

From the second letter:

Let me send you a two weeks' treatment, which is more than sufficient to completely stop the progress of the disease.

From a later letter:

In spite of the mountains of prejudice to be overcome, I intend to prove that at last something has been discovered that will destroy the Tubercle Bacillus without being detrimental in any way to the human system; in fact, besides destroying this germ, it is a strong tonic, and will invigorate a healthy body as well as bring back to its normal condition a Consumptive one....

Now you must know that throughout the world our clever Scientists and most Prominent Specialists on Consumption have for ages past spent their lives trying to find something which will destroy the Tubercle Bacillus without injuring the human system. They have had everything at their command; the most up-to-date Sanatoria, the cleverest Nurses, and the pick of climates, yet they have failed, though every drug and remedy known, including every ingredient contained in any proprietary medicine or cough mixture ever heard of has been exhaustively tested in every shape and form. My treatment differs in this one great respect, that none of the ingredients have ever been used before by any Chemist or Doctor, and are an entirely original discovery....

I will give any Doctor its formula who requests it, and will supply him free of charge with all the treatment he needs for experimental purposes, and you must see that I can gain nothing by doing all this unless my treatment positively cures Consumption, as I claim it to do.

On the back of the printed letter quoted above appeared the following:

GUARANTEE BONDS.

The following are specimens of my guarantee Bonds. No. 1, I give to any sufferer who is considered by his Doctor to have at least six months to live in the ordinary course of matters. Terms of No. 2 Bond have to be mutually arranged. I do not accept any money under this Bond until all the conditions are fulfilled.

NO. 1 GUARANTEE BOND.

To Mr. In consideration of you having paid me £2 12s. 6d. for a three months' course of my treatment for consumption, I hereby guarantee that your health has, at the end of the three months, considerably improved to the satisfaction of yourself and also of your Doctor (who must be a practitioner registered in the British Isles) under a penalty of refunding the whole of the amount paid, viz., £2 12s. 6d. (Signed) C. H. STEVENS.

Broadway, Wimbledon.

NO. 2 GUARANTEE BOND.

I hereby guarantee that it will be impossible to find any trace of the Tubercle Bacillus in your system and that you will be completely cured of Tuberculosis (consumption) to the satisfaction of your own Doctor and the Government Laboratory on or before, _____ 19___.

The only condition being that the sum of £_____, is paid to me when this guarantee is fulfilled. (Signed) C. H. STEVENS.

Broadway, Wimbledon.

These are “specimens” of guarantee Bonds. Another document, however, which appeared to be the guarantee bond actually given, differed in containing a clause by which the patient:

hereby agrees to take same [_i.e._, Stevens’ Consumption Cure] according to the directions sent out with the medicine, for three calendar months from date hereof, and to follow as far as possible the advice given regarding habits of life, diet, etc., and to fill in the form on counterfoil attached, correctly.

The “form on counterfoil attached” contained a number of questions to be answered by the patient, and also a portion “to be filled in by a Medical Practitioner after the above has been filled in by the Patient,” including such questions as:

How long have you attended to this Patient?

Do you consider this a mild, severe, or hopeless case?

Do you consider this Patient has a fair chance of recovery providing Stevens’ Consumption Cure is all it is claimed to be?

and on the back the following appeared:

This Guarantee must not be given by a chemist or any one else until it is signed by a registered Medical Practitioner to the effect that he considers the Patient to have at least six calendar months to live.

Thus the appearance was maintained of guaranteeing benefit or cure, and refunding the money if the undertaking were not fulfilled; but the conditions to be complied with were such that it appears unlikely that Mr. Stevens is ever troubled with applications for return of money under one of his “Bonds.”

A “detailed direction sheet” was supplied, from which the following is taken:

One teaspoonful in a wineglass of water (as hot as can be conveniently taken for preference) one hour before breakfast and two hours after the last meal in the evening, unless the patient be in the habit of waking between 12 midnight and 3 a.m., in which case an extra dose may be taken then. After the first week’s treatment half-an-hour before breakfast is quite sufficient.

It appears that the use of this wonderful substance is not limited to consumption cases.

Stevens’ Consumption Cure is a vegetable germicide, fatal to all disease germ growths, but acts as a strong tonic; is a blood purifier, stomach cleanser, and a nerve stimulator; one will readily understand that it must be all these to cure Consumption and build up a broken-down system entirely by itself. Stevens’ Consumption Cure can safely be advantageously given wherever a germ disease exists or is suspected.

One of the most recent circulars sent out by Mr. Stevens is addressed to medical practitioners, asking them to use his remedy in severe cases of pulmonary tuberculosis which defy all the ordinary remedies, and professing to give the formula of the preparation as follows:

Its formula is 80 grains of Umckaloabo root and 13 and one-third grains of Chijitse to every ounce, prepared according to British Pharmacopœia methods.

The medicine was a clear red liquid, and analysis showed it to contain in 100 fluid parts, 21·3 fluid parts of alcohol, 1·8 parts of glycerine, and 4 parts of solid substance; this solid substance contained about 1 part of a tannin and 0·2 part of ash, the remainder being extractive. No alkaloid was present and no other active substance could be detected. The solid substance agreed in all respects with the solids of decoction of krameria, or a mixture of this decoction with a little tincture of kino. The formula thus appears to be approximately:

Rectified spirit of wine 23·7 parts by measure. Glycerine 1·8 parts. Decoction of krameria (1 in 3) to 100 parts by measure.

or it may be made with tincture of krameria.

Estimated cost of ingredients for 2¼ fluid ounces, 1½d.

TUBERCULOZYNE.

The Derk P. Yonkerman Company, Ltd., an American company with an agency in London, charges £2 10s. 0d. for a month's treatment and supplies two bottles, labelled respectively No. 1 and No. 2 Tuberculozyne, and containing in each between 11 and 12 fluid ounces of liquid.

The advertisement offered a book on "Consumption and how it may be quickly cured," and a trial of the cure itself, to be sent free. Application for the book and sample brought bottles of "No. 1 Tuberculozyne" and "No. 2 Tuberculozyne," holding about ½ ounce each, and a book of 48 pages dealing with the remedy. A few extracts from the book will sufficiently indicate the nature of its contents.

There have been found cures for small-pox, and safe precautions, such as vaccination, prevent the spread of the disease; the horror of yellow fever has been dispelled by a remedy that amounts practically to a cure, and one could always flee to a northern clime and escape it. The dread diphtheria also has yielded up its dark secret, and now is no more a stalking spectre; while yet dangerous it can be handled.

But through all these discoveries, consumption remained as mysterious and deadly as ever. It invaded the homes of the rich and the poor. It hunted out its victims among the inhabitants of the far northland of ice and snow, and it was just as persistent in the temperate zone and at the equator.

Climate, temper, condition of health or purse made no difference. One day the health and strength of the athlete, and the next day the fever of the consumptive; in a short time the frail skeleton would be laid away—another victim. That was the oft-repeated story of the "great white plague."

But this horrible, awful consumption, that has gone stalking through the land, should never again strike the same terror to the souls of brave men and women, and fill our hearts with such a helpless despair—for consumption can now be cured. Tuberculozyne (Yonkerman), the most wonderful and marvellous medical discovery of the age, cures consumption....

After researches lasting for nearly twenty years, the persistent efforts of Dr. Derk P. Yonkerman have been crowned with success, for his Tuberculozyne treatment has already been proved in hundreds of cases to be a specific of almost miraculous curative power. Its healing virtues have been demonstrated in not only the early stages of consumption, but in far advanced and seemingly hopeless cases as well....

Tuberculozyne (Yonkerman) was such a marvellous remedy that when its discoverer first announced he could cure consumption there were few ready to believe. He had, however, discovered certain salts of copper of remarkable therapeutic value, and his production was immediately subjected to the most elaborate and rigid demonstrative tests....

The consumption germs (tubercle bacilli) cannot live in the presence of copper, and as the Tuberculozyne treatment introduces copper into the blood, the consumption germs cannot live....

Intra-Venous Injection, after thorough tests under the most favourable conditions, proved absolutely ineffective. Trachael (_sic_) Injection has also been tried with equally unsatisfactory results. Inoculation with lymph from tuberculous animals not only utterly failed, but frequently hastened the patient's death. Antimony, prussic acid, emetics, blisters, mercury, iron, digitalis, clover, and numerous other drugs, have all proved useless, for they failed to have any action upon the cause of the disease, and only gave the patient temporary relief, if they produced any beneficial effects at all.

In treating consumption in the past, physicians making Tuberculosis a speciality have been accustomed to recommend creosote and its product guaiacol, while later arsenic has found a certain amount of favour. These physicians have undoubtedly been honest and conscientious in prescribing such treatment, for they were upheld by the practice of years, and the indorsement of the greatest specialists in each generation for a hundred years. Yet they were wrong; just as wrong and just as ignorant of the true remedy for consumption as the ancients were of geography before the new world was discovered.

Against the use of creosote or guaiacol, Dr. Yonkerman speaks positively and emphatically, and his opinions have now the support of all present-day physicians making Tuberculosis their special study.

A "Life History of Dr. Derk P. Yonkerman" was also given, from which it appeared that the home of Tuberculozyne is in Michigan, U.S.A.

The book was accompanied by a long letter, and this was followed at intervals by others; these were all printed to appear as typewritten, and dealt chiefly with the terrors of consumption if neglected, the importance of taking Tuberculozyne at once, and, after a supply had been sent, with the necessity of continuing its use even if no apparent benefit results. A few extracts are here given:

You need not be discouraged or believe your case incurable, even if you have tried all the usual remedies and found no relief, for hundreds of our cured patients have had the same experience; after all other remedies had failed to even stop the progress of their disease, they tried Tuberculozyne and were quickly cured.

From the third letter:

We realize that since you were taken ill your expenses must have been burdensome, and if you feel that at the moment the cost of a complete treatment of Tuberculozyne is more than you can readily meet, we will send you the full month's supply upon receipt of but 40s.; the remaining 10s. you may pay at your own convenience when you are fully satisfied that your cure is complete and permanent.

From the fifth:

It is therefore with a genuine desire to help you that we write enclosing a Special Voucher Coupon issued in your name, which will help you materially if the cost of our remarkable specific has been more than you could really meet.... This Special Voucher Coupon which we have issued to you is good for £1 Sterling when sent with your order for Tuberculozyne. You have only to post the coupon together with 30s., and immediately we will forward to you the complete treatment and full instructions for its use.

From later letters:

Even if her improvement is not at once pronounced, do not be discouraged; for in some cases the patients at first even seemed to be losing ground, but they persevered and finally were cured. It would be much better to take the treatment a few weeks too long than to stop too soon....

Just at this time, when the patient has been taking our treatment for some weeks and it is beginning to permeate her system through and through, courage is needed, for great improvement may not yet be apparent though her cure be assured.

Every letter was accompanied with one lithographed copy, or more, of testimonials.

The directions were:

After each meal, put thirty drops of the medicine from each bottle into a tumbler of milk; stir well and drink immediately.

If milk is distasteful, the medicine may be taken in water which has been boiled.

For patients between the ages of seven and fifteen years, give one-half of the above dose; for those under seven years, give five (5) drops only, from each bottle.

No. 1 was a bright red liquid; analysis showed it to contain in 100 fluid parts, 3·4 parts of potassium bromide, 12 parts of glycerine, a trace of a pungent substance, sufficient oil of cinnamon (or oil of cassia) to give a flavour, a very small quantity of alcohol, and cochineal colouring matter darkened with a trace of alkali; no copper was present. The following formula gave an exactly similar liquid:

Potassium bromide 3·4 parts. Glycerine 12·0 " Oil of cassia 0·1 part. Tincture of capsicum 0·17 " Cochineal colouring q.s. Caustic soda 0·06 part. Water to 100 fluid parts.

No. 2 was a brown liquid, one specimen being bright and another containing a little sediment. Analysis showed it to contain in 100 fluid parts, 18 parts of glycerine, sufficient essential oil of almonds to give a flavour, and a colouring matter which appeared to be burnt sugar. No copper was found in the small free sample, but the larger bottle of No. 2 contained 0·01 per cent. of copper, and a trace of sulphate: this quantity of copper is equivalent to ¹/■■ grain of crystallised copper sulphate in each fluid drachm. As regards the other ingredients the following formula gave an exactly similar liquid:

Glycerine 18 parts. Essential oil of almond 0·1 part. Burnt sugar q.s. Water to 100 fluid parts.

The estimated cost of ingredients for No. 1 and No. 2 together is 2½d.

The following notes on some German nostrums for Consumption are derived from Dr. Zernik's articles in the _Deutsche Medicinische Wochenschrift_.

KÖRBER'S CURE FOR CONSUMPTION.

The advertisements of this preparation are described as particularly flagrant. Treatment for a fortnight costs about 12s., and the medicine contains butter fat, honey, catechu and tar-water.

BACILLENTOD.

Bacillentod or "death to bacilli" also described as a "family tea," is advertised as a miraculous preparation which cures all diseases of the respiratory tract. In the prospectus the word "phthisis" is misspelt. One packet costs 1s., and consists of 85 grams of galeopsidis, the dog, flowering, or hemp nettle, a herb which is now quite obsolete but was an ingredient of "Lieber's tea for consumption," which used to have an extended sale.

HONEY COD LIVER OIL.

Pastor Felke's Honey Cod Liver Oil is recommended in preference to the ordinary forms of cod liver oil, on account of its pleasant taste and of the absence of any disturbing effect on the digestion. It is said to contain "fat extracted cod liver oil," whatever that may mean, but proved on examination to be nothing more than a mixture of 0·05 per cent. of cod liver oil with oil of peppermint and raspberry syrup.

CHAPTER IV.

HEADACHE POWDERS.

Headache is so common a disorder that it was to be expected that secret remedies asserted to be certain and safe cures would be extensively advertised, and the sale, especially to women, of headache powders, in most cases as proprietary articles, is at the present day undoubtedly enormous. Persons who may be disposed to resort to their use should, however, bear two facts in mind; the first is that headache is not a disease but a symptom, and that the only rational treatment is to ascertain and remove the cause, whether it be error in diet, want of exercise, local irritation of some nerve as by an unhealthy tooth, eyestrain, or some serious chronic nervous disease. The second is that fatal results have been known to follow self-treatment with antifebrin (acetanilide), which figures largely in most of them.

The powders analysed were in all cases obtained from ordinary dealers in unopened packages; the composition of each is given in such a way as to show the dose of each article in one powder of average weight. Since the separation of the ingredients depends largely on their different solubilities in various liquids, it is not possible to obtain quantitative results having quite the same degree of accuracy as in some other kinds of analytical work; but the results of analysis have been checked by preparing mixtures of the composition calculated and submitting them to the same analytical process; the possible error in the proportions given below does not in any instance exceed a very small fraction.

DAISY POWDERS.

The English Company which sells this remedy charges 7½d. for 10 powders; the average weight of one powder was 6 grains, but the weight of individual powders in a packet was found to vary from 5·7 to 6·4 grains.

The medicament consisted of acetanilide alone. Being an unmixed drug it was not liable to stamp duty, and the package was accordingly unstamped. The dose was stated to be one powder, repeated in two hours if necessary; half a powder for children of 12 years; not adapted for children under 12 years.

Two "certificates" were printed on each wrapper from individuals who are notorious for giving testimonials in the guise of certificates of analysis. The only fact certified was that the powders were "free from any injurious substance," in which medical opinion will scarcely support the writers.

The estimated cost of the drug (60 grains) in a packet is one-eighth of a penny.

The same Company also supplies “Head powders prepared by Daisy, Ltd.,” the wrappers being printed in such a way that careful inspection was required to distinguish these from the powders sold as “Daisy powders.” The “head powders” were found to consist of phenacetin only.

CURIC WAFERS.

These so-called wafers, also put up by an English Company, are recommended as a “safe and certain cure for headache, toothache, and neuralgia”; stated to be prepared “from the Prescription of an Eminent West-End Physician.”

The “wafers” consisted of ordinary cachets, with the name of the article embossed on one face. They contained the medicaments in the form of powder. The package contained 12 wafers for 1s. 1½d. The average weight of the contents of one wafer was 8·2 grains, but that of the contents of individual wafers in a package varied from 7·3 to 9·3 grains. Analysis showed the composition of the powder to be:

Acetanilide 3·28 grains Phenacetin 3·28 ” Caffeine citrate 1·64 ”

Directions for taking the wafers were given, but it was not stated whether the dose is one or more.

The estimated cost of the drugs (98·4 grains) in a packet is nine-tenths of a penny.

STEARNS’S HEADACHE CURE.

This remedy, advertised by an American Company with agents in London, is recommended as “A Speedy, Certain, and Safe Cure for Headaches of all Origins, whether Sick, Bilious, Nervous, or Hysterical.”

Like the foregoing it was put up in cachets described as wafers. The package contained 12 wafers for 1s. The average weight of the powder contained in one wafer was 9·8 grains; but the weight of individual wafers in a package varied from 9·3 to 10·2 grains.

Analysis showed the composition of the powder to be:

Acetanilide 3·92 grains. Caffeine 0·98 grain. Sugar of milk 4·90 grains.

The dose was one wafer. “If relief is not obtained, repeat in an hour, but more than two wafers should not be taken.”

The estimated cost of the drugs (118 grains) in a packet is a little under ½d.

BELL’S FAIRY CURE.

This Fairy Cure, which is put up by an English Company, is stated to give relief instantly in all cases of neuralgia, headache, etc. A handbill enclosed in the package made further claims, from which the following extracts are taken, “guaranteed to be an instant and absolute cure” for “neuralgia, headache, brain fag, nerve pains.” “Nothing else is like it. Nothing else is so good. Don’t compare it with ordinary ‘cures’ or ‘powders.’ Fairy Cure stands absolutely alone.”

Ten powders were sold for 7d. The average weight of a powder was 2·7 grains, but individual powders in a package varied from 2·0 to 3·7 grains.

Analysis showed the composition of the powder to be:

Acetanilide 1·16 grains. Phenacetin 1·16 ” Caffeine 0·38 grain.

The directions were to take one powder, “repeat in an hour if necessary, then every two or three hours until a cure is effected.” Yet it is guaranteed to be an instant cure! There was a notice that it was not to be given to children below 12 years of age.

In this case also an “analyst’s report” was given on the wrapper; it stated that the powder “is composed of several organo-therapeutic agents well-known in medicine”; probably the “analyst” did not mean quite what he said in the following: “In my opinion, the preparation is well calculated to fulfil the purpose for which it is intended, namely—neurotic affections.”

The estimated cost of the drugs (27 grains) in a package is ¼d.

KAPUTINE.

This preparation, put up by an English Company, is stated to cure in ten minutes headache, neuralgia, and all nerve pains. In view of the similarity in composition of these articles, the claims to uniqueness are amusing. In this case the wrapper bore the words “Nothing as good. Nothing similar,” while on the circular enclosed in the package it was stated that “Kaputine is composed of several approved ingredients. That is, unlike the white headache powders, which consist solely of one crude drug, and which have frequently been condemned as dangerous by the Medical Press—Kaputine is most carefully prepared from several ingredients which have the absolute confidence of the Medical Profession.”

The price of 18 powders is 1s. 1½d. The average weight of one powder was 6·6 grains; the weight of individual powders in a package varied from 5·7 to 7·5 grains.

Analysis showed the composition of the powder to be:

Acetanilide 6·30 grains. Ferric oxide 0·05 ” Sugar 0·21 ”

That is, the acetanilide was tinted pink with what is practically the saccharated carbonate of iron of the _British Pharmacopœia_.

The dose was given as one powder: “If not completely cured in two hours, the dose may be repeated. Half a powder for children under 12.”

The estimated cost of the drugs (119 grains) in a packet is just over ¼d.

HOFFMAN’S HARMLESS HEADACHE POWDERS.

These powders are prepared by a New York Drug Company, but the package also bears the name of another company, presumably the English agents. The powders are described as “a simple and effective cure for all headaches.”

Ten powders were sold for 1s. 1½d. The average weight of one powder was 10·5 grains; nine out of ten weighed from 9·3 to 10·5 grains, the tenth weighing 15·3 grains.

Analysis showed the composition of the powder to be:

Acetanilide 5·02 grains. Cocoa 4·02 ” Sodium bicarbonate 1·01 ”

The dose was given as one powder, to be repeated in half an hour if not relieved.

Estimated cost of drugs (105 grains), one-third of a penny.

WHOLESALE AND RETAIL SPECIALITIES.

In addition to the above proprietary articles, large numbers of headache powders are supplied singly by retailers, and are commonly bought for this purpose ready packed from a wholesale house. It was, therefore, thought worth while to examine a sample of such powders; the one taken for the purpose is known as the “Good as Gold” headache powder; three dozen were attached to a card for exhibition, and the powders are retailed at 1d. each. The average weight was found to be 2·8 grains, six individual powders ranging from 2·7 to 2·9 grains. The powders consisted of acetanilide only.

The estimated cost of the drug for three dozen powders is ¼d.

There is reason to believe that practically all the others sold in this way are of the same composition.

CHAPTER V.

BLOOD PURIFIERS.

Although, as a rule, the makers of any kind of quack medicine find no difficulty in showing that almost any disease that can be named takes its rise in the organs or part of the system which their own particular nostrum professes to benefit, it is, of course, particularly easy to connect a great variety of diseases with the condition of the blood. The claims made for some of the following “blood purifiers” do not fail in comprehensiveness, for ringworm and itch, among other complaints, appear to be regarded as disorders of the blood.

CLARKE’S WORLD-FAMED BLOOD MIXTURE.

This is advertised and sold by an English Drug Company, price 2s. 9d. a bottle, containing 8¼ fluid ounces.

The following passages are quoted from a pamphlet enclosed with the bottle:

No matter what the symptoms may be, the real cause of a large proportion of all diseases is bad blood. Clarke's World-famed Blood Mixture is not recommended to cure every disease; on the contrary, there are many that it will not cure; but it is a guaranteed cure for all blood diseases.... It never fails to cure Scrofula, Scurvy, Scrofulous Sores, Glandular Swellings and Sores, Cancerous Ulcers, Bad Legs, Secondary Symptoms, Syphilis, Piles, Rheumatism, Gout, Dropsy, Blackheads or Pimples on the Face, Sore Eyes, Eruptions of the Skin and Blood, and Skin Diseases of every description.

On the label it was stated:

The Mixture is pleasant to the taste, and warranted free from anything injurious to the most delicate constitution of either sex, which all Pills and most Medicines sold for the above diseases contain.

Directions: The mixture must be taken about half-an-hour after meals, in the following doses:—

For Adult Males.—One tablespoonful four times a day. " _Adult Females._—One tablespoonful three times a day. " _Children under 12 years of age._—Two teaspoonfuls three times a day. " _Under 12 years._—From half to one teaspoonful, according to age, mixed with a little water and sugar.

Analysis showed the mixture to contain 1·5 per cent. of potassium iodide, 1·2 per cent. of sugar (partly inverted), 1·6 per cent. by volume of alcohol, and traces of chloroform and ammonia, a brown colour being given by a small quantity of what was evidently burnt sugar. The composition of 8 ounces is thus:

Potassium iodide 52·5 grains. Spirit of sal volatile 10 minims. Spirit of chloroform 67 " Simple syrup 50 " Burnt sugar q.s. Water to 8 fluid ounces.

The estimated cost of the ingredients is 1■d.

OLD DR. JACOB TOWNSEND'S AMERICAN SARSAPARILLA.

This is sold by a Company having offices in London. A bottle, holding a little under 9 fluid ounces, costs 2s. 6d.

On the wrapper it was stated:

This Sarsaparilla is the great purifier of the blood and general juices of the system, it effects the most salutary changes in disease; cures scrofula, salt rheum, all scorbutic disorders, chronic sore eyes, rheumatism, piles, liver complaints, erysipelas, all blotches and eruptions of the skin; in short, it removes every impurity of the blood, and all humours and morbid collections of the body.

The directions given on the label were:

Take half a wineglassful three or four times a day, an hour before or after meals. Persons very weak and debilitated may begin with a tablespoonful and increase the dose as the patient recovers health and strength. It is better to take it without the addition of water.

Analysis showed 100 fluid parts of the liquid to contain 18·2 parts of solids, of which 5·5 parts were sugar (partly inverted) and 2·5 ash, the remainder being of the nature of a vegetable extract. The mineral constituents were only those common to the ash of most drugs, and no metallic salts were found in medicinal doses; nothing of alkaloidal nature was present. The mixture contained 8·1 per cent. by volume of alcohol. In the case of a vegetable preparation of this kind, containing no definite active principle that can be identified chemically, it is not possible to state with certainty the various drugs from which it may have been prepared; a study of its general properties, and a series of careful comparisons, pointed to the present mixture being of similar nature to the compound concentrated solution of sarsaparilla (liquor sarsae compositus concentratus) of the _British Pharmacopœia_, with the omission of the liquorice, and with the addition of sugar: the drugs in the official preparation (besides liquorice) are sarsaparilla, sassafras, guaiacum wood, and mezereon. A liquor prepared in this manner, with the alcohol reduced to the amount found in the mixture under examination and the aroma slightly increased by adding a little additional oil of sassafras, agreed fairly well both in general properties and the results of chemical examination with the medicine under consideration.

MUNYON'S BLOOD CURE.

Munyon's Homœopathic Home Remedy Company has an office in London, but the label on the bottle bears the words "Manufactured in U.S. of America." On the outer package it was stated:

It eradicates all Impurities from the Blood, and cures Scrofulitic Eruptions, Rash on the Scalp, Scald Head, Itching and Burning, and any form of Unhealthy, Blotchy, Pimply, or Scaly Skin;

and similar claims were put forward on the label and in a circular enclosed with the bottle.

The bottle cost 1s. and contained about 200 pellets or pilules, of the average weight of ½ grain. They consisted of sugar; careful search was made for small quantities of medicament, but no other ingredient could be detected. Quantitative determination of the sugar showed just 100 per cent.

The estimated cost of the pilules is one-thirtieth of a penny.

HARVEY'S BLOOD PILLS.

These pills are sold by a Company giving an address in Wales. A bottle, containing 20 pills, costs 1s. 1½d.

The label and the enclosed circular bear the picture of a man's head, with the words, "Harvey. Discoverer of the circulation of the blood," with the possible implication that the Harvey who discovered the circulation of the blood also discovered or invented these blood pills.

The modest claims made in the circular included the following:

Harvey's Blood Pills for Skin Diseases. An Unfailing Remedy for Scurvy Sores! Harvey's Blood Pills for Scrofulous Sores. A Certain Remedy for Ulcerated Legs! Harvey's Blood Pills for Sluggish Liver. The Surest Remedy for Ringworm! Harvey's Blood Pills for Erysipelas. The Quickest Remedy for Itch! Harvey's Blood Pills for Boils. An Effective Remedy for Eruptions! Harvey's Blood Pills for Rheumatism. The Safest Remedy for Piles!

Harvey's Blood Pills are purely Vegetable, and contain the best properties of Sarsaparilla, Dandelion, Burdock, and Quinine. They are Warranted Free from Mercury.

Harvey's Blood Pills fortify the feeble, restore the invalid to health, and do good in all cases. All sufferers should immediately have recourse to these celebrated Pills.

Harvey's Blood Pills are "specially" suitable for Females. They remove all impurities.

Somewhat lengthy directions were given for diet, etc., as well as for taking the pills, in various cases; from which it appeared that the usual dose is:

For a male adult, one Pill three times a day; a female adult, one Pill twice a day; children one Pill at bedtime.

The pills were coated with French chalk, coloured red externally; when deprived of their coating, the average weight was 2·76 grains. Analysis showed them to contain quinine equivalent to 17·3 per cent. of the crystalline sulphate, 21·7 per cent. of potassium iodide, small proportions of powdered rhubarb and liquorice, and vegetable extract or extracts. A mass prepared from the following formula agreed closely with the pills in general properties and in results on analysis in various ways:

Quinine sulphate 17 grains. Potassium iodide 22 " Powdered rhubarb 16 " " liquorice 8 " Extract of sarsaparilla 12 " " burdock 12 " " taraxacum 12 " Divided into 36 pills.

The estimated cost of the ingredients for 20 pills is ¾d.

PROFESSOR O. PHELPS BROWN'S BLOOD PURIFIER.

Professor O. Phelps Brown advertises in this country from an address in London; the bottle sold for 2s. 9d. contained 6 fluid ounces.

The following paragraph appeared on the label:

This medicine is a concentrated preparation of Rock Rose and Stillingia, combined with other plants, well-known for their specified action on the blood, which makes a compound medicine, that has never been equalled, and will be hard to surpass in the scientific future. It is impossible to give a full account of its virtues and cleansing capacities on this label, and the Prof. must, therefore, be content with briefly stating that it is an infallible remedy for All Diseases of the Blood, be they Constitutional, Hereditary, or of Recent Contraction. Nearly every ailment known to the medical faculty is in a greater or lessor degree dependent for its appearance and its virulence upon a _Disease of the Blood_. Ulcers, Tumours, Scrofula Bunches, Fistula, Piles, Painful Eruptions, indeed all afflictions manifested upon the outer surface of the body are the consequences of diseased blood. Many terrible maladies, which take the shape of Internal Inflammation, Sores, etc., and appear in the form of Fevers, Aches, Swellings, Glandular Disturbances, Mental Derangement, and General Debility, also proceed from the same cause. It is an admitted fact that, with Pure Blood and Regular Bowels, no individual ever can be permanently, seriously, or dangerously ill, if ill at all.

Dose.—For Adults, one tablespoonful three times a day before eating. For Children, the dose must be reduced to a teaspoonful.

Analysis showed 100 fluid parts of the liquid to contain 19·7 parts of solids, of which 15·5 parts were sugar (partly inverted); a good deal of mucilage was present, but no alkaloid and no mineral substance except the small quantity of ash always present in vegetable extracts; alcohol was present to the extent of 23 per cent. by volume. Evidence was obtained of the _probable_ presence of a preparation of stillingia, but this drug does not contain any active principle by which it can be certainly identified. Rock rose (_Cistus canadensis_) has been used to some slight extent medicinally, but no particular virtues appear to have been assigned to it; it is, however, described as bitter and astringent. The 3 or 4 per cent. of extractive matter present in the mixture under consideration showed neither bitterness nor astringency, nor any property by which it could be identified, or which would indicate any medicinal properties.

HOOD’S COMPOUND EXTRACT OF SARSAPARILLA.

This is an American preparation, but the Company which makes it has offices in London. A bottle, costing 1s. 1½d., contains 2¼ fluid ounces.

The following paragraph appeared on the covering of the bottle:

A trial bottle will convince the most skeptical of the real merit of Hood’s Sarsaparilla, and will enable everybody to test its wonderful power in restoring and invigorating the whole system, in renovating and enriching the blood, in giving an appetite and a tone to the stomach, in eradicating and curing Scrofula, Scrofulous Humors, Scald Head, Syphilitic Affections, Cancerous Humors, Ringworms, Salt Rheum, Boils, Pimples and Humors on the Face, Catarrh, Headache, Dizziness, Faintness at the Stomach, Constipation, Pains in the Back, Female Weakness, General Debility, Costiveness, Biliousness, and all diseases arising from an impure state or low condition of the blood. Hood’s Sarsaparilla is designed to act upon the blood, and through that upon all the organs and tissues of the body. It has a specific action also upon the _secretions_ and _excretions_, and assists nature to expel from the system all humors, _impure particles and effete matter_ through the lungs, the liver, the kidneys, and the skin. It effectually aids _weak, impaired, and debilitated organs_, invigorates the _nervous system_, tones and strengthens the _digestive organs_, and imparts new life and energy to all the functions of the body. The peculiar point of this medicine is that it strengthens and builds up the system while it eradicates disease.

In a pamphlet enclosed with the bottle it was stated:

It is carefully prepared from Sarsaparilla, Dandelion, Mandrake, Dock, Pipsissewa, Juniper Berries, and other valuable vegetable remedies, in such a peculiar manner as to retain the full curative value of each ingredient used.

The dose was given as:

Adult, ½ to 2 teaspoonfuls; usual dose 1 teaspoonful three times a day; children, less, according to age.

Analysis showed it to contain, in 100 parts by measure, potassium iodide 1·7 parts (7½ grains in 1 fluid ounce), and sugars (partly inverted) 9·1 parts; the total solids amounted to 12·8 parts, thus leaving 2·0 parts of vegetable extract per 100 fluid parts. The concentrated compound solution of sarsaparilla in the _British Pharmacopœia_ contains about 21 parts of solids in 100 fluid parts, so that it may be concluded that the amounts of extracts of “Sarsaparilla, Dandelion, Mandrake, Dock, Pipsissewa, Juniper Berries, and other valuable vegetable remedies” in this mixture were not large. The liquid had a somewhat aromatic odour and taste, in which oil of juniper could not be detected, nor was it recognizable on distillation; none of the other ingredients mentioned is capable

of being identified in such a mixture. No alkaloid was present, and careful search for other likely ingredients gave only negative results. The mixture contained 19·6 per cent. by volume of alcohol.

HUGHES'S BLOOD PILLS.

These pills, made in Wales, are sold in boxes, price 1s. 1½d., containing 30 pills.

They were described on the label as "For all Blood, Skin, and Nerve Diseases." In a circular enclosed with the box there was a dissertation on the functions and composition of the blood, from which the following extracts, with all their capital letters, are taken:

The Blood being therefore the Life of the living Body, it stands to reason that if it is poisoned, you poison the whole system, and eventually destroy the life of the man. When the blood is chilled, or distempered through breathing impure air, unhealthy food, etc., it at once gets disturbed, and breeds disease in some form or other. This is the cause of Blast, Scurvy, Piles, Boils, King's Evil, Swollen Glands, Inflammation of the Eyes and Lids, Pains in the Sides, Back, and Kidneys, Cough, Bronchitis, Pleurisy, Rheumatism, Wounds in the Legs and Different Parts of the Body, all Scorbutic Affections, Cancer, Pimples on the Face, Neck, etc., and all Skin Eruptions, Chilliness, Headache, Indigestion, Fullness after Meals, Dyspepsia, Vomiting, Loss of Appetite, Consumption, Toothache, Neuralgia, Fits, St. Vitus's Dance, all Liver Complaints, Costiveness, Yellow Jaundice, Depression of Spirits, Stitches in the Sides, Fevers, Epidemics, Plagues, Gout, Nerve Diseases, Lumbago, Erysipelas, all kinds of Inflammation, and most Chest Diseases.

The noted Pills, "Hughes's Blood Pills," act directly upon the Blood and Juices of all parts of the system, which they Strengthen and Purify. By so doing the Liver, Kidneys, Heart, Lungs, Stomach, Bowels, Brain and Nerves are renewed and toned to such a degree that their functions are perfectly performed, securing to the man healthy days.

Very lengthy directions were given for taking the pills for a variety of complaints, from which it appeared that the usual dose was one or two pills at night, or one three times a day.

The pills had a thin loose coating of French chalk; after removing this the average weight was 2 grains. Analysis showed the presence of no inorganic salts, except the usual small quantities of phosphate, sulphate, etc., found in the ash of most vegetable drugs. The pill contained a trace of oil of cloves and consisted of powdered drugs to the extent of about half its weight; ginger and cinchona were identified in this portion; a trace of alkaloid was extracted, showing the properties of the alkaloids of cinchona. A portion of the tissue, which appeared to be derived chiefly from a seed, could not be recognized, and a lengthy series of comparisons failed to identify it. The remainder of the pill was separated into two substances, which appeared to be aloes and jalap resin, but in each a mixture as this pill presented, the identity of these substances cannot be established with complete certainty. The proportions of the ingredients, also, can only be ascertained approximately; the following formula was indicated:

Aloes 0·7 grain. Jalap resin 0·2 " Powdered cinchona bark 0·3 " " ginger 0·2 " Oil of cloves Trace. In one pill.

CHAPTER VI.

REMEDIES FOR GOUT, RHEUMATISM, AND NEURALGIA.

The medicines here described vary considerably in their nature, and to some extent in the complaints for which they are recommended, but no definite line can be drawn between them. Some are primarily for gout, but are recommended also for rheumatism; others are mainly for rheumatism, but are also recommended for gout and neuralgia; while others, again, are chiefly advertised for neuralgia and headache.

BLAIR'S GOUT AND RHEUMATIC PILLS.

These pills, which are a British product, are sold in boxes, price 1s. 1½d., and containing 14 pills.

They were described in a circular accompanying the box as:

The great and universal remedy for the immediate relief and cure of Acute and Chronic Gout, Rheumatism, Suppressed Gout, Rheumatic Gout, Gouty Skin Diseases, Bronchitis and Asthma, Sciatica, Lumbago, and Neuralgia, and as a preventive or prophylactic where the disease has a tendency to recur, or attacking any vital part, as the Stomach, Brain, or Heart.

Other extracts from this circular are:

In all cases of Gout, no matter of what length of standing, they not only give relief from the almost intolerable pain, but where the patient has kept his bed for months, _One Box will frequently carry off the attack_ in two or three days—in many cases of extreme torture relief has been obtained in two or three hours ... in those gouty skin affections, Psoriasis and Eczema, these Pills have no equal.

Blair's Gout and Rheumatic Pills are not only efficacious in curing Gout, but in all those diseases allied to it.

They never fail. They always cure.

Directions and Doses.

For Gout and Rheumatic Gout.—Take two Pills three times a day, just after meals, and when it is very severe, take two during the night, and they should be persisted in until the swelling and stiffness have disappeared.

In cases of long standing, where the tendency of the disease is to recur, it is advisable to take a short course of the Pills as a preventive. Dose.—Two twice a day for a fortnight.

For Suppressed Gout, including Gouty Asthma, Bronchitis, Dyspepsia Rheumatism, Rheumatic Headaches, Lumbago, Sciatica, Tic Doloreux, Pains in the Head, Face, etc., they must also be taken, two Pills three times a day, just after meals, that quantity being generally sufficient, but in some cases a longer continuance of them is necessary, particularly in Rheumatism of long standing, but that will also be eradicated by perseverance in the use of these Pills. _They should be taken from time to time also as a preventive._

Spring and Autumn. In these treacherous Gout and Rheumatic Seasons, to prevent a recurrence, sufferers are earnestly advised to take a short alterative course of this famous medicine.

It is requested, in case this medicine should considerably open the bowels, that it may be laid aside until that effect has ceased, when it may be resumed, beginning with a smaller dose. Patients are also informed that it is unnecessary for any aperient medicine to be taken during its use, unless they have been costive for some days.

The pills had an average weight of 2·9 grains. Analysis showed them to contain powdered colchicum corm, exsiccated alum, and an excipient. The quantities found indicated the following formula:

Powdered colchicum corm 2·1 grains. Burnt alum 0·35 grain.

in one pill.

The estimated cost of the ingredients for 14 pills is one-seventh of a penny.

HAMM'S RHEUMATIC, GOUT, AND SCIATICA CURE.

The Originator and Proprietor of this cure, who hails from the north of England, charges 2s. 9d. for a bottle containing 8 fluid ounces. It was described on the outside package as "The Greatest Remedy in the World. It has no equal for the cure of Rheumatism, Gout, and Sciatica." In a circular enclosed with the bottle it was stated that:

It never fails to Cure those distressing and torturing Complaints, and in most cases has given relief from the excruciating pains by taking a few doses. This Standard Remedy has time and again succeeded after all other internal remedies have failed. Purify the Blood by driving the Uric Acid from the system and you will remove the cause of all Rheumatism, etc. Hamm's Famous Rheumatism Cure has Never Failed to do it.

The dose was given on the label as "One Tablespoonful three times a day, after meals."

The preparation was a brown, slightly turbid liquid. Analysis showed it to contain potassium iodide, sodium salicylate, a little vegetable extractive, and a trace of alcohol. The extractive was moderately bitter, but possessed no characters indicating the drug from which it was derived; it contained no alkaloid. Quantitative determination of the ingredients showed the formula to be:

Potassium iodide 15 grains. Sodium salicylate 66 " Extractive 28 " Alcohol Trace. Water to 8 fluid ounces.

Assuming the extractive to be of the same price as extract of gentian, the estimated cost of the ingredients of 8 fluid ounces is ½d.

GLORIA TREATMENT FOR RHEUMATISM.

This “treatment” is advertised as follows:

Cure yourself of Rheumatism. I will tell you how and send you the remedy Free. My combination treatment cures, not merely relieves but actually cures, cases of Rheumatism, Gout, and Sciatica.... The numerous so-called remedies offered to the public, through the medium of the newspapers, have absolutely killed all confidence; therefore, in order to make my genuine remedy more generally known, I have decided to give away a large quantity so that everybody can test for themselves the truth of my statements. My combination treatment consists of: 1. Gloria Balm, which Instantly Relieves Pain. 2. Gloria Pills which Purify the Blood and Invigorate the Whole System. 3. Gloria Tonic Tablets which Effect a Complete and Permanent Cure.... I earnestly ask every Rheumatic Sufferer to obtain a free supply of this medicine at once. Simply send a postcard request, and a supply will reach you in less than 24 hours.

Application to the address given brought sample boxes of the pills and tablets only, accompanied by a booklet entitled “Rheumatism and Gout, Causes and Cure,” and a letter of the usual type, as indicated by the following extracts:

I was very pleased to receive your communication this morning, as having suffered from the terrible disease with which you are afflicted myself it naturally affords me a great deal of gratification to be able to place in the hands of every sufferer a genuine remedy for it—a remedy which cured me and has cured many thousands of others besides....

It is, as I have often heard it described by persons bubbling over with gratitude for their relief from the above distressing ailments, Nature’s very own cure for Rheumatism and Gout. The danger of allowing the poisonous acids which cause these diseases to continue their work day by day in the body cannot be exaggerated....

Before closing this letter I once more beg to impress upon you the danger of delay in commencing the treatment, especially as applied to your particular case.

Since “Gloria Balsam” was apparently not thought sufficiently important for a sample to be sent, supplies were obtained of the tablets and pills only for examination.

Gloria Tonic, price 4s. 6d. a box, containing 50 tablets, was described on the box as “a scientific preparation for the cure of all uric acid ailments, including Rheumatism and Gout, Lumbago, Sciatica, Scrofula, and all other diseases resulting from Impurities of the Blood.” This rather wide claim was somewhat at variance with statements made in the booklet, from which a few extracts may be given:

It was with the object of curing all rheumatism that I introduced “Gloria Tonic” to the public, and I believe that it is a task worthy of the cause. I do not propose to make the attempt with a remedy similar to the many thousands of cure-alls with which the market is overloaded, but with a true and reliable rheumatism specific—“Gloria Tonic.”

I am not offering you a remedy of that kind, but one which is solely compounded for the cure of rheumatism, one that has been tested in Hospitals and Sanatoriums, one that has the endorsement of physicians and University professors, and, above all, one which has already enabled many hundreds of persons to abandon crutch and cane. Do not wonder if this can be true. The foregoing statement is an absolute fact....

I could easily get many times 4s. 6d. for a box of “Gloria Tonic,” but it is my purpose not so much to accumulate wealth as to benefit suffering mankind....

“Gloria Tonic” is to-day the only remedy on the market that cures all forms of rheumatism effectively, and without destroying the delicate tissues of the Heart, Stomach, Liver, and Kidneys....

The merit of this remedy is unapproachable. I have no object in telling you this aside from having your interests at heart, and wish to protect you against the many harmful drugs. You need not have any fear in taking “Gloria Tonic” as directed, while the smallest dose of other rheumatic remedies might harm you.

The directions were:

For adults: From one-half to one tablet is a dose, and four doses should be taken daily as follows: Half to one tablet before the morning, noon, and evening meal, and on retiring.... Dose for children from 10 to 15 years, one half-tablet. From 5 to 10 years, one-quarter of a tablet. Below these years, the medicine should not be given.

The average weight of the tablets was 11·2 grains; among 12 weighed separately the weights varied from 10·5 to 12·5 grains. Analysis showed the presence of potassium iodide, guaiacum resin, extract of liquorice, powdered liquorice, starch, mineral matter—apparently a mixture of talc and kaolin—a resinoid substance, and a trace of alkaloid. The alkaloid amounted to 0·016 per cent.; it did not agree in properties with any of the common alkaloids, but agreed, so far as it was practicable to examine it, with the alkaloid of phytolacca (the American weed, poke-root, or pokeberry); the resinoid also agreed in its properties with the resinoid phytolaccin, but there are no distinctive tests by which its identity could be certainly established. The quantities of the various ingredients were estimated as accurately as possible, and the following formula was indicated:

Potassium iodide 1·8 grains. Guaiacum resin 0·8 grain. Extract of liquorice 1·0 ” Resinoid (phytolaccin?) 0·9 ” Powdered liquorice 1·7 grains. Rice starch 2·0 ” Talc and kaolin 2·1 ” In one tablet.

In the formula the most expensive ingredient is the phytolaccin, which is also the least certain, both as to identity and quantity. Taking the formula here given, the estimated cost of the ingredients for 50 tablets is 8d.

Gloria Pills, price 1s. 1½d. per box, containing 40 pills, in addition to being supplied as part of the “treatment” for rheumatism, were recommended as a general laxative. It was stated in the circular enclosed with them that “Gloria Laxative Pills will cure Constipation, Torpid Liver, Piles, Headache, Dizziness, Sour Eructation, Heartburn, Bloating, Flatulence, Nausea, Sleeplessness, Mental Depression, Palpitation of the Heart, Nervousness, Kidney Trouble, and all other conditions resulting from Dyspepsia and Indigestion.”

The pills were coated with talc, coloured to a chocolate colour with oxide of iron. After removal of the coating, the average weight was 1·1 grains. Analysis showed the constituents to be chiefly extracts and resins. The two samples of pills examined—namely, the gratis sample of eight pills first supplied, and the full box afterwards obtained—differed materially in composition; the former contained about 25 per cent. of powdered liquorice, 6 or 8 per cent. of powdered rhubarb, and 6 or 8 per cent. of wheat flour, while the latter contained neither liquorice nor rhubarb, and proportionately more of the soluble constituents, which appeared to consist in both cases of extracts of aloes and cascara sagrada with jalap resin. The various constituents were estimated quantitatively, but in such a mixture exact results are of course unattainable, and even the qualitative results must be given with a certain reservation. The formula indicated for the pills in the 1s. 1½d. box was:

Extract of cascara sagrada 0·3 grain. ” Socotrine aloes 0·5 ” Jalap resin 0·07 ” Flour } q.s. Excipient }

in one pill.

Estimated cost of ingredients for 40 pills, ½d.

BARING GOULD’S ANTI-RHEUMATIC PEARLS.

This article is introduced to the public by an advertisement headed:

“Rheumatism speedily cured.” The advertisement states that Mr. Baring Gould, of an address at a provincial watering place, “very strongly recommends Marvellous Cheap Remedy for Chronic Rheumatism, Gout, etc. Free Information for addressed envelope.”

Application for information with regard to the remedy brought a box of the “Pearls” with an intimation that the price was 5s., or 3s. 9d. for prompt cash. In the enclosed circulars the proprietor was described as “W. Baring Gould, Rheumatic Specialist and Scientist in Chemistry,” and the “Pearls” were referred to in the following terms:

Baring Gould’s Anti-Rheumatic “Pearls” (Patent and Trade Mark Registered). The Most Wonderful and Most Effectual “Anti-Rheumatic” Ever Known....

Mr. Baring Gould desires to say that from a recent careful examination of his records, he finds that he relieves or cures (mostly by his wonderful “Pearls”) at least eighty people in every hundred who come under his care.

There is nothing to approach the “Pearls” in Curative value for all kinds of Rheumatism, Sciatica, and Gout. They are entirely free from every kind of injurious substance, and may be taken with absolute safety and benefit by the most delicate bedridden sufferers.

DOSE.—Take 2 Pearls twice a day. Being flexible and tasteless they are easily swallowed, or the gelatine casing may be removed and the contents placed in half a wineglass of water (hot or cold) and taken in that way. The flavour of the medicaments is agreeable to the palate and to the stomach also.

The “Pearls” consisted of gelatine capsules, of the flattened form known commercially as “perles,” containing a white powder. The average weight of the contents was 5·9 grains, the contents of single capsules varying from 5·0 to 6·5 grains. It should be said that aspirin, a drug in very common use for rheumatism, is acetyl-salicylic acid. Analysis showed the powder to consist of:

Acetyl-salicylic acid 85 per cent. Sugar of milk 15 ”

The estimated cost of ingredients for 40 capsules is 1½d.

GOWER’S GREEN PILLS.

These pills, which cost 1s. 1½d. per box, containing 44 pills, were described in the advertisement as:

A real remedy for rheumatism, backache, muscular rheumatism, sciatica, gout, lumbago, cramps, stiffness of joints, kidney disorders, dropsical swellings, etc. These Pills act directly on the organic and muscular parts of the body, and bring instant relief to tired, aching, and painful muscles and joints.

In the circular enclosed with the pills it was stated that:

The ingredients ... are known only to the proprietors. They are not to be found either in the _British Pharmacopœia_ or in any surgery in the land. It was not your doctor’s fault that he did not cure you, it was his misfortune—he did not know how. He had not these remedies in his possession. We offer you the opportunity of using them and recovering your health.

Gower’s Green Pills, though an eminently scientific pill, do not act like magic. The days of miracles have gone by. They act surely, but sometimes slowly in cases of Rheumatism of long standing.

In taking these pills we would like it to be thoroughly known that if your disease is one of long standing you cannot be completely cured with one or two boxes. A rheumatic sufferer who has tried most remedies and has been tortured with pain for five years cannot expect to be a new man in five weeks. If it takes as many as a dozen 2s. 9d. boxes to cure a case like this, the sufferer cannot but consider it the best investment that he ever made in his life.

The directions were:

One dose to be taken three times a day, before or after meals. Three Pills are one dose.

The pills were coated with talc, with a small quantity of a green colouring matter. After removal of the coating the pills had an average weight of 1·2 grains. Analysis showed them to contain soap (about 36 per cent.), an alkaline salicylate (about 37 per cent.), extractive, and vegetable tissue. No alkaloid was present; the extractive was dark in colour, without bitterness or other characteristic taste, and showed no properties by which its source could be identified; microscopic examination of the tissue showed the presence of two powders, one of which agreed well in its characters with powdered cimicifuga root, while the other bore much resemblance to jalap, but not enough to warrant the statement that it was jalap. The total amount of vegetable powder was about 20 per cent., of which about one-third appeared to be cimicifuga; 11 per cent. of silicious ash was also present.

DR. COLLIE’S OINTMENT.

This ointment, supplied by a Scottish Company at the price of 1s. 9d. for a box containing 1¾ ounces, is advertised in the following terms:

Try Dr. Collie for Rheumatism. His ointment positively cures while you sleep. You don’t rub it in, but apply just like a poultice. It draws out the cause of your trouble, and a speedy cure ensues. Try Dr. Collie’s Ointment—Instant relief for Sciatica, Lumbago, and swollen joints.

It appeared, however, from a booklet sent with the ointment that rheumatism was only one among a large number of complaints for which the ointment was recommended; it was described on the label as:

A certain cure for Sprains, Bruises, Cuts, Burns, Chapped Hands, Eczema, Blood Poisoning, Whitlows, Sea Water Boils, Abscesses, Piles, Rheumatism, Sciatica, Lumbago, Pains in the Back and Loins, and all Sores and Ulcers of every description.

The directions for its use in rheumatism were:

First wash the part to be treated with warm water and soda, then thoroughly dry—(a quantity of the ointment may then be well rubbed in). Now get a piece of thick cotton cloth (old sheeting answers very well) or better still, chamois leather, spread the ointment thickly and apply like a poultice. When the dressing begins to get dry, take it off, and after scraping the cloth replace it with fresh ointment. The part may, after a dressing or two, begin to itch, and the skin, being stimulated, may come out in a humour. If so, do not be alarmed but persevere. This is a sure sign that the Ointment is doing its work, drawing out the deleterious matter, viz., Uric Acid Poison, from the body through the most natural of all channels, the pores of the skin.

Analysis showed the presence of colophony resin, petroleum jelly, a little beeswax, and a fatty base. The colophony was accompanied by a small proportion of another substance of resinous nature, which appeared to be the altered resin to be found in the variety of colophony known commercially as “black resin”; a dark substance was also present which appeared to consist of the natural impurities of crude petroleum; the fatty basis showed generally the properties of a mixture of lard and tallow. A similar ointment was obtained by using the following formula:

Black resin 12 per cent. Beeswax 2 ” Crude petroleum jelly 26 ” Tallow 20 ” Lard 40 ”

Estimated cost of ingredients for 1¾ ounces, 1d.

ZOX.

Zox is a powder made by a Company with an address in London and the price charged is 1s. for a box containing eight powders. It was described on the wrapper as:

The most marvellous pain reliever. Instantly cures Toothache, Neuralgia, Headache, Sciatica, and all Nerve Pains. Pure, Harmless, not Aperient.

In a circular enclosed with the box directions were given for taking the powders for neuralgia, toothache, headache, sciatica, rheumatic and gouty pains, and influenza. For neuralgia the directions were:

Ono Powder should be taken when in pain, and should the enemy return, continue the Powders every four hours, for a few days. If very weak from continual pain, take a few doses of Zox Tonic; this will give you speedy relief.

For rheumatic and gout pains:

Take one Zox Powder two or three times a day while pain is acute; avoid beer and spirits of all kinds.

The average weight of the powders was 4½ grains, single powders in a box varying in weight from 4 to 6 grains. Analysis showed the powder to consist of acetanilide only.

The estimated cost of the drug for eight powders is one-tenth of a penny.

OQUIT.

The vendors, a Company with a London address, sell tubes of 20 tablets for 1s. 1½d.

This is advertised as follows:

Neuralgia. Within 10 minutes of taking “Oquit” that frightful nerve-racking pain will be cured. One dose will convince you. Try it.

A pamphlet was enclosed with the package, headed “Oquit for Headaches and Nerve Pains, Headache, Neuralgia, Gout, Sciatica, Rheumatism, Lumbago, Influenza, Feverish Colds, Sea Sickness.” A few extracts are here given:

Oquit ... is made in strict accordance with a medical prescription from drugs which are daily prescribed by the most eminent physicians for the relief of nerve pains. There is nothing experimental about “Oquit.” The drugs of which “Oquit” is composed are perfectly well known, and their claim to be regarded as unrivalled for the purpose has been rigidly tested and endorsed by the leading exponents of modern medicine. What is really unique about “Oquit” is the scientific proportion in which the constituent drugs

are combined. It is a remarkable fact, and one which is attested by every medical man, that the action of a drug may be made effective or ineffective according to the manner in which it is prescribed. There are certain subordinate drugs which prepare the way, as it were, for the action of a principal drug, and the proportion between the ingredients of a prescription is of vital importance in relation to the effect produced. It is to this scientifically adjusted proportion that the remarkably beneficial results of “Oquit” are due....

In the cure of Neuralgia, “Oquit” has proved eminently successful when taken in the same way as recommended for headache, with the addition that a third and further doses should be repeated, if found necessary, at intervals of three hours....

In Rheumatism, whether the acute or chronic forms, “Oquit” is extremely beneficial, expelling from the system the inflammatory agents which give rise to the frequently excruciating pains in the joints and muscles involved, and confers a most welcome relief....

In Gout, Sciatica, and Lumbago the eliminating power of “Oquit” is of the greatest possible value. In all these cases, adults should take three “Oquits” every three hours at the commencement of an attack, reducing the dose to two, and then to one, as the pain decreases.

The average weight of the tablet was 5·1 grains. Analysis showed them to contain:

Acetyl-salicylic acid 66·2 per cent. Starch, chiefly maize 20·0 ” Talc 4·2 ” Gum 1·5 ” Extractive 3·1 ” Moisture 5·0 ” Alkaloid a trace.

As stated above aspirin is acetyl-salicylic acid, and so it may be added is xaxa.

The alkaloid did not show well-marked characters by which it could be identified, but agreed fairly well in its reactions with the total alkaloid of gelsemium; the general nature of the extractive was consistent with its being a preparation of this drug.

The estimated cost of ingredients for 20 tablets is ¾d.

GENOFORM TABLETS.

A substance was described under the name Genoform in the _Pharmaceutische Post_ in 1905, as being the methylene-glycol ester of salicylic acid; but as the present preparation is advertised to the public, and supplied under a patent medicine stamp, it must be regarded as a secret remedy. The proprietor, it is stated, resides in Leipzig but there is a London agency, and the remedy is sold in tubes price 1s. 1½d., containing 10 tablets.

An advertisement of this preparation was headed: “Gout, Rheumatism, Sciatica, and Neuralgia Cured. A Miracle in Rheumatism.” Then followed a testimonial describing the “miracle.” On the package of the tablets it was stated that:

Genoform cures gout, rheumatism, sciatica, neuralgia, etc. Genoform gives instant relief and effects a permanent cure.

A circular enclosed in the package stated:

Genoform is a certain cure, and you need not suffer another day. No matter where the pain is, or how severe it is, or how long you have had it, Genoform Tablets will rid you of it. They give relief in many cases immediately, and produce a permanent cure.

Take them to-day and feel well. Genoform eases pain with a rapidity which is remarkable, at the same time doing away with the cause. Remember that.

It is no mere relief. It stamps out the cause of Gout, Rheumatism, Sciatica, and Neuralgia. It is absolutely harmless. No remedy equals it in its quick and certain effects.

Patients afflicted for years and unable to walk or use their limbs have been made sound and free from pain in a very little time....

Absolutely crippled rheumatic persons, unable to dress or undress themselves, have entirely recovered with only a few doses of this preparation.

The directions were as follows:

The Tablets must never be taken on an empty stomach, but either during or after meals (from 3 to 9 tablets daily). Taking the Tablet is facilitated by letting it soak first in a spoonful of water and drinking a little water afterwards. Any oppression of the stomach is soon relieved by 5 or 6 drops of dilute Hydrochloric acid taken in half a glassful of water.

As Genoform contains Salicylic Acid and that well-known drug for Rheumatism sometimes causes a little buzzing in the ears, if such buzzing ever occurs it is well to discontinue Genoform for 24 hours and afterwards take only a small dose for a day or so. It must be clearly understood that there is no possible harm or danger in such buzzing and few persons are so affected, but we think it wise to advise you lest you should think Genoform does not agree with you and discontinue its use.

The tablets had an average weight of 7·7 grains. They contained no free salicylic acid, but on hydrolysis with alkali they yielded 91·0 per cent. of that substance. Starch was present to the extent of 4·1 per cent., so that the material other than starch yielded 94·9 per cent. of its weight of salicylic acid. Salicyl-methylene-glycol ester CH■(C■H■O■)■ would yield 95·6 per cent.; investigation of the other products of hydrolysis showed that this ester was the substance present; no other ingredient was found. On examination the substance proved to be hydrolyzed at once by alkali in the cold, but not by cold dilute acid; hot water caused slight decomposition, and on boiling it in water it readily yielded salicylic acid. The formula of the tablets is thus:

Salicyl-methylene-glycol ester 95 per cent. Starch (and moisture) 5 ”

POST’S C. B. Q. TABLETS FOR RHEUMATISM.

Two specimens of the proprietary article sold under the name of C. B. Q. have been examined at an interval of nine years. The earlier analysis showed that the tablets contained potassium iodide, quinine and colchicine in small quantities, a salicylate and extract of liquorice, used no doubt to bind the powder together. The analysis made in 1908 showed that of the tablets then examined each contained about 1½ grains of potassium iodide, a small quantity of salicylate, a vegetable extract, and magnesia. The extract was hygroscopic and the magnesia was no doubt employed to bring the mixture into a form suitable for tablet making. The extract was slightly bitter and the tablets contained a small amount of alkaloid, which was not certainly identified.

GOUT VARALETTES.

Analysis of Bishop’s Gout Varalettes showed the presence of lithium citrate and a small quantity of what appeared to be piperazine, together with the usual effervescing basis consisting of sodium bicarbonate and tartaric acid.

PISTOIA GOUT POWDERS.

There was a powder for gout known to an earlier generation under the name of the “Portland Gout Powder;” according to the prescription given by Jourdan in the _Pharmacopée Universelle_ (1828); it consisted of: Gentian root, round birthwort root (_Aristolochia rotunda_), ground pine root (_Teucrium chamaepitys_), the tops of germander (_Teucrium chamaedrys_), and of the lesser centaury (_Erithroea centaurium_), of each equal parts to be ground separately to a fine powder and mixed; dose, half a teaspoonful. He gives of this three variants, in one of which the gentian is replaced by guaiacum.

For some years past a good deal has been heard about the Pistoia gout powders. A pamphlet entitled _The antigouty powders of the R.R. Benedictine Mothers of Pistoia for the treatment of a gouty source_ (Rome, 1904) presents a curious resemblance to the advertising pamphlets issued by ordinary nostrum dealers. There is a short disquisition on gout written in very odd English, this is followed by a translation of a large number of testimonials to the virtues of the powder, and this again by the following “Warning to our Customers”:

Having known that in some towns of Italy, and even in Pistoia, some antigouty drug circulates under the name of “Vegetal Antigouty Powders of the Cloister” or under other names alike, making every body trust that they come from our Monastery, we think ourselves, in duty bound, to remember to our Customers that no deposit of our Antigouty Powders is to be found neither in Pistoia nor in other towns or places in Italy or abroad, and that we have accorded to nobody the faculty of preparing or selling them.

Consequently every antigouty remedy which in any way should be made known as coming from this Monastery, must be considered as a product of vulgar falsification and adulteration.

The label on some boxes of the powder states that it is based on gentian, and on Indian wood, which is one of the synonyms of guaiacum. The pamphlet, which has already been quoted, states that the powders do not contain colchicum, belladonna, or any other poisonous substance, but

are a composition of medicinal grasses, none of which can ever have a pernicious effect upon the health, whatever may be the state of the person who uses it.

It is asserted that “often many miraculous cures are obtained,” but it appears that the treatment must be a prolonged one, for the pamphlet further states that:

When it is question of a first affection or of a light gouty attack, the treatment of a whole year without interruption can in general be sufficient; because it is necessary for the blood to stay under the action essentially depurative of the drug during four seasons.

But when the illness is old, a year of treatment cannot of course be enough to extirpate entirely the distemper, and the use of the drug must be protracted till necessary.

The sample of Pistoia gout powder examined was of a greenish ginger colour and had a bitter taste. MM. Guignard, Collin, Chastaing, and Barillot give the following formula for the Pistoia gout powder:

Colchicum corm 10 parts Bryony root 10 ” Betony (root, stem, and leaves) 50 ” Gentian root 10 ” Camomile (chiefly stem, leaves, a little root, and flowers) 10 ”

M. Collin is one of the leading authorities on the microscopic characters of powdered vegetable drugs, and a microscopical examination of the specimen revealed characters consistent with this formula; such small differences as were observed were only such as might be expected between specimens grown under different conditions of soil, climate, etc.

Another formula which has been published for the powders is as follows, but the sample examined agreed more nearly with No. 1:

II.

Colchicum corm 20 parts. Bryony root 10 ” Betony root 40 ” Gentian root 10 ” Camomile 10 ”

LAVILLE’S ANTIGOUT REMEDIES.

According to Zernik, the chief constituents of the Liqueur du Dr. Laville, an antigout remedy, very popular in France, in spite of its high price and secret composition, are colchicin (about 0·08 per cent.) and quinine in alcoholic solution. The pilules du Dr. Laville are sold as preventive remedies against gout. They were found to contain extract of winter cherry, Physalis alkekengi, one of the Solanaceae (? capsicum), guaiacum resin, powdered leaves and root of the marsh mallow, and sodium silicate. Each bottle contains 75 grams, about 2½ fluid ounces, and costs 8s.

SOME GERMAN NOSTRUMS.

The following notes upon a few German remedies are quoted from Dr. Zernik’s reports in the _Deutsche Medicinische Wochenschrift_.

URICEDIN.

This is a Berlin product vaunted as a remedy for the gouty diathesis, but its composition is very simple; it contains 2½ per cent. sodium chlorate, and 66·5 per cent. dry sodium sulphate, the remainder being sodium citrate and sodium tartrate.

RHEUMACID.

The prospectus asserts that this material, the result of years of careful and earnest study, revolutionizes all medical knowledge, and cures rheumatism, colds, neuralgia, sciatica, gout, bladder, kidney, and skin affections, etc. The price demanded for 50 grams (about 1½ ounces) is 17s. 6d., while a sample costs 1s. The sample is supposed to contain ten doses of 1 gram each, but was actually found to contain only half that quantity. There appeared to be three sorts of rheumacid, marked A, B, and C respectively, but the analysis revealed that the constituents were practically the same and included aspirin, salol, and at times salpyrin, with a little citric acid. This seems rather like making a revolution with rosewater.

ANTIGOUT SOAP.

Lazarus Gout and Rheumatic Soap is prepared in Dresden. It is a piece of medium-quality sodium soap, containing a very small quantity of an ethereal oil. The cake weighs 70 grams (about 2 oz.), and costs 1 mark.

PINE PREPARATIONS.

Electricum, described as “aethereal Tyrolese fir and pine wood oil,” and recommended by the vendors as an external remedy for rheumatism, gout, pains in the limbs, paralysis, sciatica, lumbago, and backache, neuralgia, tumours, etc., seems to consist merely of pine oil.

Weigand’s Rheumatic and Gout Spirit which it is stated relieves the pain within a few hours and cures after a short time, consists of 55 parts of turpentine oil, 55 parts of spirits of camphor, and 5 grams of Venice soap. A bottle containing 115 grams, less than 4 ounces, costs 2s. 6d.

RHEUMA TABAKOLIN.

This is a Berlin preparation; a box containing about 100 grams (about 3½ oz.) costs 5s., but the quantity for neglected and obstinate cases cost 15s. It is asserted to be a newly discovered remedy for rheumatism and gout obtained from tobacco. The directions are to extract the material with about 24 ounces of 50 per cent. alcohol, and to use this extract as a liquid application to the painful areas. Analysis showed that the substance consisted of waste and powdered tobacco perfumed with lemon oil. In Germany waste broken tobacco can be bought at about 5d. or 6d. a pound.

CHAPTER VII.

KIDNEY MEDICINES.

This group of nostrums consists of those which are put forward for the cure of kidney troubles, or conditions of ill-health commonly, but as a rule erroneously, attributed by the public to kidney disease. Several of these are in the form of pills, while others are liquids. The two principal drugs employed are oil of juniper and potassium nitrate (nitre or saltpetre), separately or together; in some cases aperients are added. Altogether extravagant claims are made for some of the articles, as is usual, of course, with proprietary medicines; this point is dealt with more fully in the descriptions of individual preparations.

In analysing complex mixtures, such as some of these nostrums are, it is, of course, not possible to attain the same precision as when dealing with medicines which consist chiefly of inorganic salts, as in the case of nostrums for epilepsy, dealt with in another chapter. A vegetable extract containing no definite active principle, such as, for instance, extract of taraxacum (dandelion), cannot be identified by any direct test; if such an extract is mixed with another, with a powdered drug, or an essential oil, its identification with perfect certainty may become almost impossible. The large variations, again, which may occur in the proportion of solid matter in a tincture or infusion, as well as the variations in the relative proportion of the different constituents of drugs, prevent the results of analysis being translated with certainty into the formula from which the mixture was compounded. These considerations apply to several of the articles described in this chapter. While the principal ingredient or ingredients in each case can be ascertained with little or no possibility of error, the subsidiary ingredients in some cases cannot be determined with the same confidence; we have endeavoured to indicate in each case the possibility of such minor errors. Full use has been made of check methods, by compounding mixtures according to the formulæ obtained by analysis and comparing them with the originals.

DOAN’S BACKACHE KIDNEY PILLS.

These pills, of American origin, which have been very extensively advertised for some years, are sold in boxes price 2s. 9d., containing 40 “kidney pills” and 4 “dinner pills.”

They were described on the wrapper of the package as a

Specific for kidney complaints and all diseases arising from disorder of the kidneys and bladder. Cure Backache, Weak Back, Rheumatism, Diabetes, Congestion of the Kidneys, Inflammation of the bladder, Gravel, Bright’s Disease, Scalding Urine, and all Urinary troubles.

A circular was enclosed with the box, in which a dissertation on “Diseases of the Kidneys and Bladder” was given, together with directions for taking the pills for various complaints. The following extracts are taken from the circular:

Doan’s Backache Kidney Pills are composed of rare and valuable medicinal agents in a combination best adapted to the speedy relief and cure of Kidney Disease, urinary and bladder affections, and all diseases resulting therefrom. They are purely vegetable, containing no ingredients of a deleterious nature, and may be taken by the most delicate person, with every confidence of their giving quick and permanent relief, without any after ill effects ... they are the only medicine known that quickly relieves and

permanently cures.

This medicine has restored to health thousands of women. As a means of healing the kidneys, and as a tonic to the whole female constitution it is unequalled.

The last sentence of the next extract shows some ingenuity:

Chronic cases of long standing. These frequently come under our notice and we hear that the patient, after trying every known remedy and failed (_sic_) has despaired of ever getting relief. Now in all stages of Kidney Disease this is where Doan's Backache Kidney Pills are the most needed, and, indeed, are the only remedy possible to give permanent relief. But it takes time. One cannot expect to be cured in a few weeks.... In some cases three or four boxes of Doan's Backache Kidney Pills are sufficient; but in these cases of long standing, 8, 10, and even 20 or 30, are required to effect a cure. But they will cure in the end if the patient perseveres. We are emphatic on this point, because in kidney disease patients are so easily discouraged. It is one of the symptoms of the disease.

The directions were to take from two to four of the dinner pills at night before commencing to take the kidney pills; then to begin with one kidney pill after each meal and one at bedtime, increasing the dose to two or three, after a short time. For children under 8, the dose was given as half a pill after each meal and at bedtime.

The "kidney pills" were ovoid in shape, and of a brown-grey colour externally, with sugar-coating beneath the thin, coloured layer; after removing the coating, the average weight of the pills was about 2 grains. Analysis showed them to contain oil of juniper and (in spite of their "purely vegetable" nature) potassium nitrate, together with a considerable proportion of a resinous substance, and of powdered fenugreek seeds and wheat and maize starches. Examination of the resin showed it to be derived from a coniferous source, and on comparison with various coniferous resins it agreed in characters with that of _Abies canadensis_ (_Pinus canadensis_), known as hemlock pitch. The proportions of the different ingredients were determined by analysis; but oil of juniper, in such small quantity, can only be approximately determined, and the amount found was confirmed by comparison of a pill containing this quantity with the pill under examination. The following formula gives a similar pill:

Oil of juniper 1 drop. Hemlock pitch 10 grains. Potassium nitrate 5 " Powdered fenugreek 17 " Wheat flour 4 " Maize starch 2 " In twenty pills.

The estimated cost of the materials of the 40 kidney pills and 4 dinner pills, ½d.

The dinner pills, of which four were included in the box of kidney pills, are also supplied separately in boxes of 50 for 1s. 1½d. The label stated that:

Doan's Dinner Pills Cure Constipation, Sick Headache, Biliousness, Dizziness, and all deranged conditions of Stomach, Liver, and Bowels.

The directions were:

For adults, 1 to 3 Pills; for children, ½ to 1 Pill.

These statements and directions were amplified in a handbill enclosed in the package.

The pills were ovoid and enclosed in white sugar-coating; the average weight of one, without coating, was about ¾ gr. Analysis showed the presence of podophyllin, aloin, oil of peppermint, a resin that appeared to be jalap resin, cayenne, liquorice, gum, maize starch, and a small quantity of an extract that resembled extract of henbane; as the extract last named had no sufficiently well-marked characters to enable a small quantity of it to be distinguished perfectly when mixed with larger quantities of the other drugs named, the identity of this ingredient could not be completely established. The following formula gives a similar pill:

Oil of peppermint 1 drop. Podophyllin 3·8 grains. Aloin 6·9 " Jalap resin 0·8 grain. Powdered capsicum 0·5 " " liquorice 0·6 " Maize starch 0·5 " Acacia gum 1·5 grains. Extract of henbane 1·5 " In twenty pills.

Estimated cost of materials of 50 pills, 1d.

DODD'S KIDNEY PILLS.

These pills, made by an American Company advertising from a London address, are sold in boxes containing 35, price 2s. 9d.

The label round the box stated:

A positive cure for all kidney diseases: cures rheumatism, Bright's disease, diabetes, backache; cures female weakness, purifies the blood, cleanses the system.

The following extracts are from a circular enclosed with the pills:

Experience has proved that Dodd's Kidney Pills are the only cure for kidney diseases.

Dodd's Kidney Pills is the only remedy that has cured Bright's Disease.

Diabetes—Dodd's Kidney Pills will cure this disease.

Dropsy—The first object in treating dropsy is to restore the kidneys to their normal condition. This is what Dodd's Kidney Pills do and hence their peculiar efficacy for this disease.

Dodd's Kidney Pills will cure any form of heart disease.

What is known as the "change of life," is a period of great importance to woman. At such a time, no remedy could be more effective than Dodd's Kidney Pills.

These pills ... consist of the active principles of vegetable substances, which have been carefully studied by the discoverer of the remedy, both as to their nature and effect, and finally given to the world in the form of a sugar-coated pill, which to-day is universally acknowledged to be the best kidney remedy obtainable.

The directions are:

Take one to three pills morning, noon, and night, before or after meals. In the majority of cases one pill is a dose.

The pills were ovoid in shape, coated and coloured red on the outside. The colouring matter formed a strongly fluorescent yellow solution, showing it to be fluorescein or an allied substance; the coating was of sugar on the outside, with an inner layer consisting of chalk. In spite of the statement quoted above, that the pills consist of the active principles of vegetable substances, it was no surprise to find that the principal ingredient was potassium nitrate, of which each contained about 1 gr.; the other constituents were sodium bicarbonate, soap, hard paraffin, wheat flour, powdered turmeric, two resins respectively soluble and insoluble in ether, a small quantity of a bitter substance, and a little extractive. Examination of the resins showed that they agreed in their characters with the two constituents of jalap resin; the bitter substance was not alkaloidal, and after careful comparison with a large number of bitter principles was found to agree with that of cascarilla. The following formula gives a pill which is practically identical with the one under examination:

Extract of cascarilla (alcoholic) 0·15 grain. Jalap resin 0·3 " Hard soap 1·0 " Potassium nitrate 1·0 " Sodium bicarbonate 0·85 " Hard paraffin 0·5 " Turmeric 0·3 " Wheat flour 0·8 " In one pill.

The estimated cost of the materials of 35 pills is 1d.

DR. VAR'S AMERICAN KIDNEY PILLS.

On the outside of the package these pills, which are advertised from an address in a town in the south of England, and sold in boxes of 14 costing 1s. 1½d., are stated to "correct the stomach and stimulate the liver and kidneys." In a circular enclosed with the box they are referred to as "Certain Corrective! Positive Cure!" while the obscurity of the following is perhaps intended to make the warning conveyed more effective:

Do not let slight or severe Kidney Disorders develop into Cancerous Decay, Twin Complaints—Kidney Liver Diseases. Cure them! Put both in strong active order. There is not a safer, surer, speedier remedy in existence. Myriads of people thank Providence for Dr. Var's Kidney Pills. _Should be taken for Natural Weak Kidneys._

The directions are:

One to be taken three times a day after meals.

The “pills” were in reality flexible capsules, each containing about 5½ grains of a soft mass in which oils of juniper and peppermint could be recognized in small quantity; examination also showed the presence of potassium nitrate, of small quantities of iron and magnesium compounds, and of lycopodium,[1] together with powdered squill, wheat starch, and a “green” extract, containing a trace of alkaloid, which appeared from its characters to be a mixture of extracts of henbane and taraxacum. The iron was perhaps an accidental impurity, and the magnesia and lycopodium were probably added to assist in making up the mass and not for therapeutic effect. The following formula gives a similar mass:

Oil of peppermint 1 drop. ” juniper 8 drops. Potassium nitrate 8 grains. Powdered squill 3 ” Wheat flour 6 ” Extract of henbane 7 ” ” taraxacum 21 ” In 10 capsules.

The estimated cost of the materials of 14 capsules is under ¾d.

[1] Lycopodium is a fine powder consisting of plant-spores sometimes used by pharmacists for enveloping pills which easily take up moisture.

FITCH’S KIDNEY AND LIVER COOLER.

A bottle of this preparation containing rather less than 4 fluid ounces is sold for 2s. The directions are:

Take two teaspoonfuls mixed in water every morning.

The label and package appear to have been devised for the purpose of suggesting, without explicitly stating, that it is a cure for the complaints named. On one side appears the following (divided into sections by use of different type):

Oh my back, how it aches! Why? Fitch’s Kidney and Liver Cooler. Trade Mark. Sluggish liver. Inactive kidneys. Over-heated blood. Bad urine. Acts chemically by absorption.

and on the other:

Oh my back, how it aches! Why? Because your Kidneys and Liver are Sluggish, and a deposit has formed in the urine which will contaminate the whole system unless dissolved chemically. Try this; you won’t regret. It’s a grand conception.

Analysis showed the liquid to consist simply of a solution of potassium nitrate in water, the strength being 56 grains in a fluid ounce—that is, 14 grains in a dose.

The estimated cost of the contents of the bottle is one-eighth of a penny.

WARNER’S “SAFE” CURE.

Warner’s Safe Cure is a liquid sold in a bottle holding about 8 fluid ounces at the price of 2s. 9d.

The label bore the words, “For Kidney and Liver and Bright’s disease and jaundice, gravel, stone”—and a long list of other complaints. “Dose for adults, one tablespoonful 5 or 6 times a day.”

A “medical pamphlet” of 34 pages accompanied the bottle, from which the following extracts are taken:

Warner’s “Safe” Cure is a purely vegetable compound, and contains no narcotic or harmful drugs; it is free from sediment and is pleasant to take; it is a most valuable and effective tonic; it stimulates digestion, awakens the torpid liver, and puts the entire system in the very best receptive state for the work of restoring the kidneys. It does its work with absolute method, preparing the tissues, soothing and stimulating the enfeebled organs, healing at the same time. It builds up the body, gives it strength, and restores the energy which is or has been wasting under the baneful suffering of kidney disease. Warner’s “Safe” Cure was discovered about thirty years ago by one of the most eminent specialists in diseases of the kidneys, who had made a life-study of kidney and kindred diseases.

How to test your kidneys. Put some morning urine in a glass or bottle; let it stand for twenty-four hours; if there is a reddish sediment in the bottom of the glass, or if the urine is cloudy or milky, or if you see particles or germs floating about in it, your kidneys are diseased and you should lose no time but get a bottle of Warner’s “Safe” Cure, as it is dangerous to neglect your kidneys for even one day. Bright’s disease, gravel, liver complaint, pains in the back, rheumatism, rheumatic gout, inflammation of bladder, stone in the bladder, uric acid poison, dropsy, eczema, scrofula, blood disease, offensive odour from sweating, so-called

‘female weakness,’ painful periods, too frequent desire to urinate, and painful passing of urine are all caused by diseased kidneys, and can be speedily cured by Warner’s “Safe” Cure, which has been prescribed for twenty-five years.”

Of Bright’s disease it is remarked:

It is one of the harassing complaints which physicians in family practice seldom have the patience to investigate and manage with sufficient care.

The assumed predilection of the public for vegetable remedies is no doubt answerable for potassium nitrate being classed as “purely vegetable” in so many of these medicines. In the present case analysis showed the presence of potassium nitrate, alcohol, glycerine, a trace of oil of wintergreen, and vegetable extractive; there was no alkaloid or similar active principle, and the extract had little distinctive taste or character; all its properties pointed to its consisting largely of extract of taraxacum, with some other extract containing a small quantity of tannin; a careful series of comparisons with all the drugs in ordinary use which were not excluded by various tests did not identify it with any of them, and it is probable that it is obtained from some non-medicinal plant.

The following formula gives an almost identical mixture:

Potassium nitrate 50 grains. Oil of gaultheria ■ minim. Rectified spirit 5 fluid drams. Liquid extract of taraxacum 10 ” Glycerine 4 ” Water to 8 fluid ounces.

This contains about 10 per cent. of pure alcohol, which is the proportion found in Warner’s Cure; in a mixture of which a tablespoonful was to be taken five or six—or, according to the handbill with it, six to eight—times a day, this proportion of alcohol is by no means negligible.

In such a mixture there is no means of determining exactly the amount of liquid extract of taraxacum, especially as it is liable to vary considerably in colour and in amount of solid residue; this is by far the most expensive ingredient in the above formula, and it is probable that the amount is here over-estimated. Taking the quantity here given, the estimated cost of the drugs for one bottle of the mixture is 5¼d.

VENO’S SEAWEED TONIC.

The Company in Manchester which advertises Veno’s Seaweed Tonic sells it at the price of 1s. 1½d. a bottle, holding 2¾ to 3 fluid ounces.

The label states:

Contains in a pleasant and agreeable form the active principles of seaweed. First introduced into the medical world by Mr. Veno, and now admitted to be a most efficient and valuable medicine. Veno’s seaweed tonic is prepared on an entirely new principle, and is free from poisonous or mineral drugs. It cures all ailments arising from a diseased condition of the Stomach, Liver, Kidneys, and Blood, which, when diseased, cause nearly all sickness. Dose.—For an adult, one teaspoonful twice or three times daily.

The following extracts are taken from a pamphlet enclosed with the bottle:

Veno’s Seaweed Tonic is a specific remedy; money cannot make it better. If it fails, no other medicine will ever succeed; but sufferers must have patience.

Kidney Diseases, Weak Back, Backache or Lumbago, Incipient Bright’s Disease. If you suffer from a weak back, with pain, soreness, or stiffness; if there is a dragging weakness in the limbs and lack of muscular energy; or if your urine is very clear or high coloured, showing a sediment of white flakes through it, it indicates a weakness or disease of the kidneys. Veno’s Seaweed Tonic should be taken for at least two or three months, in teaspoonful doses twice or three times daily, after meals.

The mixture contained a small proportion of undissolved sediment, which, when collected and examined, agreed in all respects with the insoluble portion of leptandrin. Glycerine, a little phosphate, alcohol, and a trace of chloroform were present, and vegetable extractive. Careful examination of the latter gave evidence of the presence of the constituents of cascara sagrada, senna, and rhubarb. Such a mixture as this could not, of course, be quantitatively resolved into its components, and the proportions given below were arrived at by comparisons of the properties of various trial mixtures with the properties of the original; no indication was obtained of any substance derived from seaweed. The following formula gives a practically identical mixture:

Leptandrin 10 grains. Sodium phosphate, crystals 33 ” Liquid extract of cascara sagrada 45 minims. Concentrated infusion of rhubarb (1-7) 1 fluid dram. ” ” senna (1-7) 2½ fluid drams. Glycerine 2 ” Chloroform water 1 fluid ounce. Water to 3 fluid ounces.

The estimated cost of the ingredients is 1½d.

MUNYON’S KIDNEY CURE.

This is sold by Munyon’s Homœopathic Home Remedy Company from an address in London, but is stated to be “Manufactured in U.S. of America.” The price is 1s. a bottle, containing 132 pilules.

The directions are: “Four pellets every hour,” which must at least keep the patient amused.

The label bears the words:

Cures Bright’s disease, gravel, all urinary troubles, and pain in the back or groins from kidney diseases.

The following extracts are from a circular enclosed with the bottle:

Munyon’s Improved Homœopathic Remedies are radically different from those used by the regular school of homœopathy or any other system of medicine. We have the true cure for the most obstinate as well as the most intricate of diseases. The whole secret of Munyon’s Remedies is the science of combining and harmonizing all drugs that are known to cure certain diseases, so that by our special combinations we cover every phase of the case, no matter what the complaint. There is no experimenting, no guesswork, but an absolutely fixed law of cure.

Munyon’s Kidney Cure has no equal. It cures pain in the back, loins, or groins, from kidney disease, puffy and flabby face, dropsy of the feet and limbs, frequent desire to pass water, scanty urine, dark-coloured and turbid urine sediment in the urine, gravel in the bladder, and too-great a flow of urine.

The pilules were found to vary much in size, the average weight being 0·6 grain. Analysis showed them to consist of ordinary white sugar; no trace could be detected of any alkaloid or other active principle, or of any medication. The sugar was determined quantitatively, and found to be just 100·0 per cent. of the weight of the pilules.

Estimated cost of contents of bottle, one thirty-fifth of a penny.

CHAPTER VIII.

DIABETES.

Diabetes, being a disease which runs on the whole a steady course unaffected by anything but diet, does not afford a promising field for the use of drugs; but as drowning men catch at straws, patients who have been told that they are incurable are naturally disposed to try any remedy that holds out a prospect of cure or relief. Although there are a good many proprietary remedies for diabetes, few seem to have a large sale, but such as exist are pushed by the usual pretensions set forth in advertisements and circulars. Every one must admit that few things can be more cruel than to trade upon the hopes and fears of sick people or to sell them worthless remedies with the positive assurance of cure. Yet this is what is done by the sellers of quack remedies, and the Inland Revenue pockets the patent medicine duty without a blush. Some account is here given of two much advertised preparations—Vin Urané Pesqui and Dill’s Diabetic Mixture. It may be objected that Pesqui’s Uranium Wine is not a secret remedy because it is said to contain uranium nitrate, pepsin, and “other appropriate elements” added to “old Bordeaux wine”; but uranium nitrate is a drug well-known to the medical profession, and whatever may be its properties it is not a cure for diabetes. There is no trustworthy evidence that it has ever cured a single case, and the most that can be honestly said of it is that patients have improved in general health while taking it, although it has not influenced the amount of sugar. Yet we are told in this advertisement that Pesqui’s Uranium Wine “positively cures sugared diabetes provided it is resorted to at an early stage and used during a sufficient length of time.” Dill’s Diabetic Mixture appears to consist mainly of extract of hydrastis, a well-known drug, which amongst the many virtues claimed for it has never been shown to possess any influence over diabetes; yet the advertisement says that Dill’s Diabetic Mixture is the “only known remedy for this deadly disease”! There is another triple nostrum for diabetes which, on examination, was found to consist of tablets of aspirin, unsweetened lime-juice, and a pink powder composed of sodium sulphate flavoured with oil of peppermint and tinted with phenolphthalein. These simple remedies were solemnly vouched for by the vendors in the following words: “We have satisfied ourselves that the treatment is an absolute and permanent cure”! Apparently the law cannot reach those

who publish deliberately untruthful statements with the object of selling their goods. The words of the judgment of the Lord Justice Clerk in a case with reference to Bile Beans, heard on appeal in the Court of Session at Edinburgh, should have aroused the Government to a sense of its duty to provide protection to the public. The Lord Justice Clerk exposed in plain language the procedure by which the vendors of this nostrum had worked up their business and palmed off their medicine on the public, yet the number of their advertisements does not appear to have diminished.

VIN URANÉ PESQUI.

This medicated wine is made in Bordeaux but is sold in this country from a depôt in London. The price charged for a bottle holding 24 fluid ounces is 8s.

A small booklet, entitled _Diabetes and its Cure by the Vin Urané Pesqui_, was enclosed with the bottle; a few extracts from this are here given:

It has been shown by medical statistics that there are in France every year 10,000 deaths or more, due to diabetes through a deficient treatment, whilst they could have been cured by taking the Vin Urané Pesqui....

Organic sugar enters the blood together with the alimentary sugar, the former being destroyed by the molecular changes that it undergoes for the nutrition of the different organs. If not sufficiently destroyed, it is productive of glycohemia, and as it passes into the urine it brings forth glycosuria; this pathological state determines, in course of time, particularly among persons suffering from obesity, some of the following diseases: polydipsy (excessive thirst), oedema in the legs, the enfeeblement of the physical and intellectual faculties, visionary troubles, amblyopia, cataract or gutta-opaca, headaches and anaemia, followed by dryness of the skin, successive furuncles, gatherings or boils, eczemas, itching on the skin provoking an irresistible desire to scratch one self, anthrax, urinary gravel, lumbago, sciatica, albuminuria, polyuria (insipid diabetes, without sugar, excessive emission of urine), rheumatism, dropsy, bulimia (insatiable appetite) or polyphagia, azoturia (large quantity of urine with a heavy percentage of uric acid), then fearful complications; pneumonia, prurience, either vulvar or prepucial; diabetic phimosis, gangrene in different parts of the body, particularly in the toes, the nails of which become black; consumption, etc. Great mental worries are also productive of glycosuria....

Pesqui’s Urané Wine positively cures sugared diabetes, provided it is resorted to at an early stage and used during a sufficient length of time.

As soon as the patient has made use of this wine, his thirst is allayed almost instantaneously; his strength reappears; all his functions are gradually restored; his breathing, which the absence of feculents had rendered difficult, becomes easier; he is no longer put out of breath, nor does he feel any lassitude; he can now walk about without undergoing any fatigue; his look improves and his temper assumes a more pleasant character....

The Vin Urané (Uranated Wine) prepared by Mr. Pesqui, of Bordeaux, has been qualitatively analysed at the Barral chemistry laboratory. The result of this analysis points to this medicine being a compound of old Bordeaux wine, in accordance with Bouchardat’s prescriptions, to which the following elements have been added: azotate of uranium, pepsine, and other appropriate elements.

The dose was given on the label as:

Three small sherry-glassfuls per day, with or without water, 5 minutes before, or immediately after meals, and at night before bedtime.

Analysis of the wine showed it to contain, in 100 parts by measure

Alcohol 8·75 parts. Glycerine 3·55 ” Total solids 2·92 ” Fixed acid, reckoned as tartaric 0·43 part. Volatile acid, reckoned as acetic 0·21 ” Reducing sugar 0·28 ” Cane sugar doubtful trace. Ash 0·30 part. Uranium, equivalent to crystalline uranium nitrate 0·02 ”

No digestive power whatever on egg-albumen could be detected, indicating the absence of unchanged pepsin. The amount of uranium found corresponds to one-twelfth of a grain of the nitrate in 1 fluid ounce, or half a grain in the daily dose, a sherry glass usually holding about 2 ounces.

The cost of the preparation depends, of course, on the cost of the original wine, and is scarcely affected by the added ingredients.

DILL'S DIABETIC MIXTURE.

This mixture is sold by a firm in Manchester at the price of 8s. 3d. for three bottles (not supplied singly), holding 2 fluid ounces each.

It was advertised in the following terms:

DIABETES.

Dill's Diabetic Mixture is the only known remedy for this deadly disease. No dieting necessary. It also cures Yellow Jaundice, Gall Stones, Hepatic Asthma, and all Liver Complaints. It is also the very best remedy we know for Kidney Diseases.

In a leaflet enclosed in the package it is stated:

In Diabetes the Government returns of health show that 100 per cent. die of the disease—that is, all of them—66 out of every 100 die of Coma, and 34 of Pneumonia, so that in ordinary medicine there is no cure. But after 15 years' experiment I discovered this remedy, by means of which hundreds have been restored to health and strength, the world and their families. It is the only known remedy for this deadly disease....

... all Liver complaints and Kidney complaints are cured by this remedy. And it is natural that it should be so, for when we know that the Liver is the workshop of the body; that it makes the Blood, and the Bile, and the Urine, and the Sugar which the kidneys only filter out, I say, when we know this, we may be quite sure that any remedy that cures the liver benefits the whole body. The nerves, the flesh, the skin, the blood, and tissues; even the special senses such as sight, hearing, and smell, with the sense of touch are all improved and benefited by it.

The Remedy, it is needless to say, will have to be persevered with. These are deadly diseases and must have time.

The dose was given on the label as:

One teaspoonful every four hours in a tablespoonful of water.

The mixture contained a considerable amount of sediment, partly of a heavy nature and partly very light; this caused some difficulty in dividing the contents of a bottle without altering the relative proportions of the ingredients, and increased the possible error in the quantitative results. Alcohol was present to the extent of 35 per cent.; the heavier sediment consisted of sodium bicarbonate, which is very little soluble in such a liquid; this constituent formed 7·4 per cent. of the mixture. Two alkaloids were present in approximately equal proportions, the total amounting to 0·25 per cent.; these proved to be hydrastine and berberine, and the general nature of the extractive, etc., present showed that they had been added in the form of extract, fluid extract, or tincture of hydrastis; there is no official standard for the alkaloidal strength of these, but, taking the usual proportion, the alkaloid found would represent 1·5 per cent. of extract of hydrastis. This left a portion of the total solids to be accounted for; a small amount of a resin was found which resembled scammony resin in its properties, and a larger proportion of a resinoid having general resemblance to caulophyllin (obtained from the blue cohosh or squaw-root), but the identity of the resin and resinoid could not be established owing to the absence of characteristic properties. The formula was thus found to be:

Sodium bicarbonate 7·4 parts. Extract of hydrastis 1·5 " Resin, resinoid, and other extractive 2·2 " Alcohol 35 " Water to 100 "

On the rather liberal assumption that the whole of the unidentified portion costs as much as caulophyllin, the estimated cost of the ingredients for 6 fluid ounces is 11d.

LANCASHIRE NOSTRUM

A treatment for diabetes was, and perhaps is still advertised by a firm of manufacturing chemists in Manchester. In a letter addressed to an enquirer the manufacturers wrote:

The treatment was recently discovered by a Lancashire doctor who had himself suffered from diabetes for a great number of years, and used all the recognized medical treatments without effect. His own discovery cured him entirely. The formulas have been entrusted to us, and we are manufacturing and offering the preparation to the suffering public. We have satisfied ourselves that the treatment is an absolute and permanent cure.... We have, therefore, every confidence in recommending it to you.

These statements are supported by a batch of testimonials which are not so strong as is usual in such cases. For example, one is headed in black type, "Completely cured a gentleman and his two friends," and runs as follows:

Dear Sir,—I received the treatment yesterday. A friend of mine, a London gentleman, has told me your treatment and the Gluten Bread has (_sic_) completely cured him and two friends of his of sugar diabetes.

The medicines supplied consisted of (1) tablets, of which four were to be taken each morning, and (2) a mixture. A month's supply was forwarded for 10s. 6d., from two to four months' treatment being said to be sufficient. A booklet was also sent giving the usual directions for a diet free from carbohydrates, and enjoining the use of warm clothing, with occasional hot or Turkish baths. The tablets (1) contained 5 grains of aspirin; the mixture (2) was composed of unsweetened lime-juice containing 6 per cent. of free citric acid. A pink powder, described as an aperient, consisted of dried sodium sulphate, flavoured with oil of peppermint, and tinted with phenolphthalein. These remedies are not new, nor has their use been attended with any particular success in the treatment of diabetes. It is difficult to see why they should give better results when supplied as a nostrum than when ordered in the usual way by medical men, unless we attribute something to the suggestive power of bold assertions and public advertisement.

NOTE ON DIABETIC FOODS.

In the treatment of diabetes it is the rule, in order to diminish the amount of sugar passed, to decrease or altogether exclude starchy foods from the dietary, and to replace them by various substitutes, of which the most important are gluten bread and biscuits. Some of the so-called gluten flour and special foods sold as suitable for diabetic patients are impositions, inasmuch as they are found to contain either as much or nearly as much starch as ordinary flour. In one instance brought to notice at the end of 1905, a so-called gluten flour and special diabetic foods obtained from Messrs. H. H. Warner and Co., Ltd., who are also the vendors of Warner's Safe Cure, but who in this instance acted as agents, it was found that the flour was practically ordinary wheaten flour. This is indicated in the following table, in which the result of the analysis of the special articles is placed side by side with the figures of the official analysis of wheaten flour published by the United States Department of Agriculture:

---------- | Department of | The Special |Agriculture, U.S.A.| Materials.
+---------+---------+---------+---------- | Spring | Winter | Gluten | Special | Wheat. | Wheat. | Flour. | Diabetic | | | | Food.
+---------+---------+---------+---------- Water | 10·4 | 10·5 | 12·65 | 11·06 Proteid | 12·5 | 11·8 | 10·60 | 12·40 Fat | 2·2 | 2·1 | — | 3·00 Convertible carbohydrates | 71·2 | 72·0 | 70·30 | 71·06 Mineral matter | 1·9 | 1·8 | 0·44 | 1·52 Fibre | 1·8 | 1·8 | — | —
----------+---------+---------+---------+----------

It will be seen that the amount of starch and other convertible carbohydrates in spring wheat is 71·2, and in the so-called gluten flour 70·30.

CHAPTER IX.

OBESITY CURES.

The claims made for nostrums advertised for the reduction of corpulence are, as a rule, rather less extravagant than usual. A reason for this is not far to seek; it is important that the consumer of the medicine shall be encouraged to persist in its use for a considerable time, and statements as to rapid cure might very soon be found to be at variance with the facts and would probably only lead to discontinuance of the medicine, and therefore defeat the maker's object. Nevertheless, the emphatic and confident statements, backed by testimonials, so important a weapon of the nostrum vendor, are by no means abandoned, as some of the quotations below will show. The prices named for the various articles described refer, as a rule, to the smallest size of package; in most cases larger packages, containing sufficient for several weeks' or months' consumption, are supplied at proportionally lower rates, and purchasers are urged to obtain these larger packages.

While certain of these preparations present no particular difficulty to the analyst, the majority not only contain vegetable preparations devoid of well-marked characters, but since the most important of these, extract and fluid extract of _Fucus vesiculosus_, are not prepared according to any official formula, and are naturally therefore liable to great variation, it is not possible to arrive with perfect certainty at the precise composition of such articles by analysis; and when, as in the case of any nostrum, the maker can draw on all unofficial and even non-medicinal substances for his ingredients, it is inevitable that some shall remain not certainly identified. It may fairly be assumed, however, that such unknown substances, possessing no well-defined chemical characters, will not be likely to have much, if any, therapeutic importance.

The belief that sucking lemons will make one thin is widespread, and gave origin a few years ago to a passing fashion, so that it was impossible to go anywhere, in private house or club, without meeting some gouty man or too stout lady who asserted that a

sure cure and preventive for either condition was some drink made with a fresh lemon. It was not surprising, therefore, to find that the chief ingredient in two of the secret remedies first analysed was citric acid.

Bladderwrack (_Fucus vesiculosus_) is a common seaweed which has earned, it is not quite easy to understand on what grounds, a reputation for reducing corpulency. It contains sodium salts in rather large quantities, and a small proportion of iodine, much less than many other sea-weeds. In Ireland it was once thought to be good for pigs, making them fat, and if it has an opposite effect on human beings, that effect must be very slight and uncertain.

Still, if people like to pay an absurdly high price for citric acid or extract of bladderwrack under other names, it would, perhaps, be churlish to object, but the case is rather different with the extract or other preparation of the thyroid gland found to be present in two of the nostrums most recently analysed. Medical men are not infrequently asked by patients for information or for their opinion with regard to some substance that has been praised in a family newspaper or other easily inspired or corrupted medium to which some authority is ascribed, and the detection of thyroid gland in two of the preparations analysed justifies a note of warning. The administration of thyroid requires to be carefully regulated, and its employment in self-medication cannot be regarded as a safe proceeding. Under these circumstances it can hardly be necessary to say that postal communication with the vendors of the medicines in question, even when accompanied by the patient's answers to printed questions and description of his symptoms, is not only of no value, but may be a source of danger by giving a false sense of security.

It is curious indeed to note that one of these secret preparations, Marmola, does not appear to be advertised to the public as a proprietary article at all, but is named as one ingredient among others in a prescription which is recommended in a paragraph apparently dictated solely by pity for suffering fat people; the chemist to whom the prescription will be taken to be compounded, however, is the recipient of advertising matter urging him to lay in a stock of the article to be in readiness for the demand. It is to be hoped that no chemist would dispense such a "prescription" without making it clear to his customer that what is supplied is a proprietary article, about the usefulness or innocuousness of which he knows nothing; otherwise the customer, who finds it named along with preparations bearing the letters "B.P.," is likely to suppose that it is a known substance, and that the dispensing of the prescription by a chemist indicates that the mixture is a proper and safe one to take. Two of the other preparations described are evidently usually or always supplied to the public without the agency of any retailer, the vendor thus securing the whole profit, which, it will be seen, is considerable. In both these cases the attempt is clearly made to get the customer to pay at once for as large a quantity as possible, presumably because he will be less likely to do so after giving the medicines a trial. The most alluring prospects are, of course, held out in the advertisements, but when the customer has been drawn into correspondence, and especially after he has begun to send his money, a process of "hedging" begins, as will be seen from the extracts quoted from letters sent by the vendors.

Phenolphthalein—a chemical body sold sometimes under the trade names purgen, laxoin, laxatol, laxen, etc.—appears as an ingredient in two of the nostrums, and formamine (hexamethylene-tetramine)—which goes also by many names, urotropine, cystamin, cystogen, metramine, and vesalvine among others—in one, the preparation containing the latter is said to have been devised as the result of an accident in the laboratory, in which a piece of fat became changed into oil without the rupture of the fat cells, a statement which suggests that the advertiser thinks that fat in the human body is solid like tallow or lard.

ANTIPON.

This preparation is sold by a Company with offices in London. The bottle in which it is sent out holds a little over 6½ fluid ounces and costs 2s. 6d. It bears no label, but has the word "Antipon" blown in the glass. A circular enclosed with the bottle gives a number of rules on the subject of dietary, together with statements as to the merits of the article, from which the following extracts are taken:

As a really permanent cure for corpulence, combining remarkable fat-reducing properties with tonic principles of the highest quality, "Antipon" is justly regarded by the most competent authorities as one of the most valuable discoveries in modern therapeutics, solving once and for all the vexed question of the radical cure of obesity without harmful after-effects. "Antipon" absolutely and definitely replaces all the weakening and frequently dangerous processes, systems and medicines which have hitherto done duty as remedies for the disease of obesity. It provides the medical practitioner and the public with a powerful and entirely harmless specific not hitherto within their reach.

Within a day and a night of taking the first dose there will be a reduction of weight varying from 8 oz. to 3lb., in extreme cases even more. The subsequent daily decrease will be persistent until normal weight and dimensions are attained, when the doses may be discontinued.

Directions for Use.—Take two dessertspoonfuls in half a wineglassful of water, immediately after meals. N.B.—After taking dose, cork the bottle securely.

Analysis showed the liquid to be a solution of citric acid in water, of the strength of 39·3 grains in a fluid ounce; a red colouring substance was also present, and O·4 per cent. of alcohol, the latter being doubtless introduced with the colouring. The red colour could be perfectly matched with cochineal, but the behaviour towards alkalies and other reagents showed differences; cochineal, with the addition of a little methyl orange, however, showed in most respects a similar behaviour.

The estimated cost of ingredients for 6½ fluid ounces is 1■d.

RUSSELL'S ANTI-CORPULENT PREPARATION.

This preparation is sold from an address in London and like the previous one, was in a bottle bearing no label; the letters "F.C.R." were blown in the glass, and the bottle, which held 12½ fluid ounces and cost 6s., was enclosed in a perfectly plain case, with no printed matter accompanying it. A pamphlet on the subject of the medicine was posted separately to the person ordering it; in this it was explained that:

Acting upon the many suggestions received, principally from ladies, the bottles are packed quite plainly, and without the ordinary trade labels usually found upon medicines, etc. The box is quite devoid of advertisements or anything whatever likely to denote its contents. The servants and others attached to the household may therefore be safely entrusted to open the box; inquisitiveness, if present, will not be rewarded.

In this pamphlet very detailed directions were also given for taking the medicine, and for diet and exercise. It was stated that:

In a very short space of time, say twenty-four hours, a considerable quantity of the most unhealthy fat will have been removed from that part of the system most in need of relief from the adipose matter oppressing it (the quantity varies from 8 oz. to 2 lb., or even more).

The dose is one tablespoonful in a half-wineglassful of water, within, say, ten minutes after each meal.

Analysis showed the liquid to consist of a solution of citric acid in water, containing 37 grains in a fluid ounce. The orange colour was found to be due to iron, which was present to the extent of 0·012 per cent.; and 0·4 per cent. of alcohol was also found. Addition of this proportion of iron in the form of the ammonio-citrate was found to give a practically identical colour, and the formula is approximately:

Citric acid 37 grains. Iron and ammonium citrate ¼ grain. Rectified spirit 2 minims. Water To 1 fluid ounce.

The estimated cost of the ingredients for 12½ fluid ounces is 2·1d.

ABSORBIT REDUCING PASTE AND J. Z. OBESITY TABLETS.

These two preparations are sold by a "Hygienic Skin Specialist." The paste, or, perhaps, both preparations, appear to be also known under the name of "Zobeide," as the paste was supplied in response to an order for "Zobeida," and the jar bore a label giving a so-called "analysis" (which it is needless to say was no analysis) beginning, "We have carefully examined the Zobeide Tissue Absorbers and Paste." The price of the paste was 3s. 6d., and the jar contained just over 2 ounces. The directions on the label were:

Rub in a circular direction, at night, where needed, for five minutes or more; firm, even movements, and only use as much as the skin will absorb.

The paste was a pink ointment, containing 93 per cent. of a fatty basis, 4·8 per cent. of a substance which agreed in its characters with dried bile, and was evidently ordinary "purified ox-bile," and a little carmine, the remainder being moisture. Further examination of the fatty basis showed a considerable proportion of beeswax, and the analytical results obtained agreed with a mixture of:

Beeswax 23 parts. Lard 46 " Rapeseed (colza) oil 31 "

It is not possible, however, to assign an exact formula to a mixture of fatty substances like this. The composition of the paste was approximately:

Purified ox-bile 5 per cent. Beeswax 22 ” Lard 44 ” Oil 29 ” Carmine q.s. A trace of perfume was also present.

The estimated cost of ingredients (2 ounces) is 3d.

The tablets are sold in boxes, containing 25, price, 2s.

The directions were:

Two at night dissolved in the mouth as an ordinary lozenge.

The tablets were flat oval lozenges weighing 19 grains each. Analysis showed their composition to be as follows:—

Sulphur 24 per cent. Ginger, about 4 ” Sugar 61 ” Acacia gum 8 ” Moisture 3 ”

The estimated cost of the ingredients for 25 lozenges is ½d.

XL REDUCING PILLS AND REDUCING LOTION.

Hughes & Hughes’s XL Reducing Pills and Ointment are advertised from an address in a seaside town. The pills are sold in boxes containing 28, price 2s. 9d. a box. The preparation was described, in a circular enclosed with the box, as:

A remedy at once safe, speedy, and efficacious, and of marked value from the health point of view, as it combats the special ills to which the corpulent have a liability. It is very easy to take, the pills being tasteless, and does not necessarily oblige any special course of diet.

The directions were:

2 pills, twice a day, after principal meals.

The pills were coated with French chalk, and coloured pink on the outside. After removal of the coating they had an average weight of 3 grains. Analysis showed them to contain a vegetable extract, powdered ginger, powdered liquorice, iron, potassium, phosphate, and iodide; in addition to the mineral constituents just named, the ash showed all the constituents of the ash of extract of bladderwrack; various other tests applied to the pills indicated this extract to be present, and failed to show any other ingredients. The quantities of the respective substances were determined as accurately as possible, and the formula found to be approximately:

Potassium iodide 0·15 grain. Iron phosphate 0·35 ” Powdered ginger 0·2 ” ” liquorice 0·1 ” Extract of _Fucus vesiculosus_ 2·2 grains. In one pill.

The estimated cost of the ingredients for 28 pills is 1¼d.

The Reducing Lotion for external use only with the XL reducing Pills is sold at 4s. 6d. a bottle, containing 2¼ fluid ounces.

Directions for Use.—To a little of the lotion add three or four times the amount of water (to a spoonful, three or four spoonfuls of water). The lotion is in a highly concentrated form, and equals a bottle four times the size. The lotion should be applied night and morning, gently, without rubbing, by means of the hand, or a piece of rag, to the part desired. Any part that is abnormally enlarged can be so treated, except the face, to which it should not be applied. The XL lotion will not irritate the most delicate skin, but it should not be used when there is any scratch or abrasion.

Analysis showed the presence of chloride, bromide, and iodide of potassium, glycerine, and a small quantity of a resinous substance in combination with alkali. The amount of the last constituent was very small, the resinous substance only amounting to 0·08 per cent.; it was somewhat bitter, with little colour, and showed no characteristic reactions or properties by which it could be identified. The proportions of the other ingredients were found to be:

Potassium iodide 9·7 grains. ” bromide 13·5 ” ” chloride 6·9 ” Glycerine 105 minims. Water To 1 fluid ounce.

The estimated cost of the ingredients (2¼ fluid ounces) is about ¾d.

TRILENE TABLETS.

These tablets are advertised from an address in London, in boxes price 2s. 6d., containing 66 tablets.

Enclosed with the package was a little book containing testimonials, directions, etc., and also a small circular giving instructions as to diet, with the addition:

We desire to say that such precautions are not indispensable by any means, but we formulate the above for the guidance of those in whom any peculiarity of Constitution may render such care salutary, and to promote rapidity of cure.

The directions were:

Three of the tablets three times a day 10 minutes before meals, either dissolved on the tongue or taken as pills. (_No change of diet being essential._)

It was also added:

The present supply lasts one week, in which time the weight begins to lessen, but a marked change in appearance naturally occupies _several weeks_ to effect.

Two separate packages of the tablets were obtained for analysis at an interval of several weeks; in the first supply the tablets were of a dirty white colour and contained no dye, but in the second they were bright yellow, and contained a yellow dye, which appeared to be one of the coal-tar colours; the other ingredients were the same as those found on the first occasion. The average weight of one tablet was 0·9 grain, and they were found to contain 87 per cent. of sugar, 2·4 per cent. of moisture, and O·5 per cent. of ash; about three-quarters of the remainder was starch, principally potato starch, but with a little maize. The residual 2 or 3 per cent. was a gelatinous substance which showed no marked reactions or characters, and exhibited only traces of cell tissue when examined microscopically. Analysis of the ash showed it to contain sodium, potassium, calcium and magnesium chloride, sulphate, and phosphate; these are the constant constituents of the ash of extract of _Fucus vesiculosus_; an aqueous extract of the tablets contained a small quantity of mucilage similar to that yielded by the same drug. By taking some _Fucus vesiculosus_ in the wet state, pounding it to a pulp and boiling it, a material was obtained agreeing with the gelatinous substance from the tablets, and there appeared no ground for doubting the identity of the two. Careful search was made for alkaloids and other substances in small quantity, but without any being found. The formula thus became:

Fucus vesiculosus, in pulp 3 per cent. (dry weight). Starch 7 ” Sugar 87 ” Water 3 ” Yellow dye q.s.

The estimated cost of the ingredients (66 tablets) is one-fortieth of a penny.

HARGREAVE’S REDUCING WAFERS.

This preparation is supplied from an address in London in boxes price 1s. 1½d., containing 21.

The following extracts are taken from a circular enclosed with the box; the circular contained also a number of testimonials, with directions, etc.

Purely vegetable. Contain nothing harmful. Can be taken at any time with perfect safety. Dose: Three wafers daily. One after Breakfast, Dinner and Supper. If Supper is not taken, one after Tea instead. May be dissolved on the tongue or taken as pills. No change in diet necessary.

The supply sent herewith lasts one week, in which time the Fat commences to get less. In most cases, however, to complete a cure takes about seven weeks, therefore clients should now send for the further six weeks’ treatment.

The “wafers” were really compressed tablets of the ordinary shape, coated with French chalk, and coloured pink externally with eosin. After removing the coating the average weight of the tablets was 2·4 grains; they consisted of substances of “extract” nature, with about 10 per cent. of powdered liquorice. Analysis of the ash showed all the constituents of the ash of extract of _Fucus vesiculosus_ (bladderwrack), and other tests indicated that this extract formed about one-half of the tablet; the other constituent (or constituents) also of “extract” nature, showed no reactions or properties by which it could be identified, and it was probably present merely as excipient.

ALLAN’S ANTI-FAT.

This substance is supplied by an American “Botanic Medicine Company” from a London office, in bottles containing 6½ fluid ounces, price 6s. 6d.

On the wrapper appeared the words:

Purely vegetable. Perfectly harmless. Always efficacious.

We call special attention to the efficacy of our Anti-Fat in the cure of that distressing complaint—indigestion or dyspepsia. It acts solely upon the food in the stomach, regulating and putting the liver and discharging organs in good working order.

A circular was enclosed with the bottle, entitled, “How to get lean without starvation,” from which the following extracts are taken:

A very extensive observation has convinced us, since our first circular treatise was issued, that in the majority of cases the Anti-Fat must be taken for from two to three, and, in rare cases, even four weeks before the patient will begin to notice much reduction of flesh, after which the loss goes on rapidly—generally from three to five pounds a week. In some cases the diminution in weight commences from the first two or three days’ use of it.

The treatment of obesity has hitherto rested on no sure basis.

Through the study of physiological chemistry, a _specific_ has at length been discovered, which, from the name of the discoverer, has been called Allan’s Anti-Fat.

Directions: Take two teaspoonfuls of the Anti-Fat in a wineglass full of water or sweet milk before each meal.

A small slip was also enclosed headed “CAUTION!!” which stated:

The color, as well as the flavor, of the Anti-Fat, varies somewhat with age and exposure to light, but neither in the least impairs its virtues. The temperature of the weather at the time of the manufacture of this remedy has also much to do with its clearness, or transparency, but does not affect its properties.

Analysis showed the presence of alcohol, glycerine, potassium iodide, salicylic acid, and a vegetable extract which from its properties and the analysis of the ash was evidently a purified extract of _Fucus vesiculosus_. The proportion of the latter drug represented could not, of course, be determined with certainty for the reasons already given, but the amounts of the other ingredients were ascertained by analysis, and the formula was approximately as follows:

Potassium iodide 0·3 grain. Salicylic acid 1·0 ” Glycerine 40 minims. Fluid extract of _Fucus vesiculosus_ 70 ” Water To 1 fluid ounce.

The estimated cost of the ingredients (6½ fluid ounces) is 3d.

MARMOLA.

This preparation is supplied by another American Company, which also has a depôt in London. It is sold in packages, containing ½ ounce, price 2s. 6d.

This preparation, which has been largely advertised in daily and weekly newspapers, is not represented as a proprietary article, but is mentioned as one ingredient of a prescription to be made up at a chemist’s. The following advertisement is a sample:

Is Fatness a Social Offence?

“The female form, being capable of expressing a supreme degree of grace, should be an inspiration in our daily lives and lead up to higher ideals of beauty,” said an art lecturer lately. Therefore the fat woman is an enemy to the artistic uplift, for she is entirely too heavy for any wings of fancy to raise.

Why should any woman remain fat when it is so easy to reduce one’s flesh? A woman may take but little exercise and enjoy the best of food, and still preserve a beautiful figure. She has at hand a simple fat-reducer that takes the place of starving and gymnastics. It consists of a dessertspoonful after meals and at bedtime of this simple mixture: One half-ounce of Marmola, one ounce of fluid extract of Glycyrrhiza B.P., one ounce of pure Glycerine B.P., and Peppermint Water to make six ounces in all. Every over-fat person should try it. It’s quite harmless, and will take off as much as a pound of fat a day. With a chemist’s handy, anyone can have a good figure at a reasonable cost.

A dessertspoonful of the mixture prescribed would contain about 9 or 10 grains of Marmola. The prescription and directions were reproduced on the label of the package, and it was added:

If faithfully taken as directed for 60 or 90 days, satisfactory results should be obtained.

which is a decidedly milder statement than that in the advertisement that it “will take off as much as a pound of fat a day.”

The box contained a light brown powder, and analysis showed the presence of (1) a large proportion of a powdered seaweed, agreeing well in characters with the powder of _Fucus vesiculosus_, its identity being further indicated by the composition of the ash; (2) a substance of proteid nature, agreeing well in characters with the powder of dried thyroid gland, its identity being further indicated by the presence of iodine in organic combination; (3) phenolphthalein; (4) sodium chloride (common salt); and (5) extractive. The last showed no well-marked characters by which it could be identified, and differed both in quantity and some minor properties from the extracts obtained from a specimen of powdered fucus which was used for comparison. This difference might quite well be due to differences in the drug or in the treatment it had received, or the extract may represent some other ingredient possessed of no distinctive characters; a trace of oil of peppermint was also present.

Although it was easy to ascertain the nature of the ingredients the determination of the proportions in which they were present in such a mixture offered no little difficulty. It is not necessary to detail here the methods employed, but it will suffice to say that while every care was taken to make the results as accurate as possible, they cannot in the nature of the case be more than approximate. The formula arrived at was:

In one Dose. Dried thyroid gland 14 per cent. 1·4 grain. Phenolphthalein 4 ” 0·4 ” Sodium chloride 7 ” 0·7 ” Powdered _Fucus vesiculosus_ 50 ” 5·0 grains. Extractive 25 ” 2·5 ” Oil of peppermint trace trace.

Taking the “extractive” at the price of some of the commoner medicinal extracts, the estimated cost of the ingredients for half an ounce is about 4d.

FIGUROIDS.

The tablets sold under the name of Figuroids are or were recently supplied by a London Company, price 2s. 9d. per bottle, containing 12 large and 12 small tablets.

They were described in a pamphlet enclosed in the package as

A Scientific Obesity Cure discovered through an accident while making Scientific Investigations in the Laboratory.

Other extracts from the pamphlet are as follows:

In looking through quantities of anti-fat literature one finds all kinds of crude, ignorant explanations, such as, for example, that the remedy absorbs the fat. Now, a sponge absorbs water, or any dry thing will absorb a liquid, but common sense will tell you that a liquid taken into the body will not absorb fat; you can clearly understand that point without further explanation. Another remedy, it is claimed, simply destroys the fat. This explanation is, as you can see, equally preposterous. In Nature nothing is destroyed. When a piece of coal is burned it is not destroyed, it is only changed into gases and smoke, and fat is not destroyed by any remedy.

Now here is the true and scientific explanation. When Figuroids are taken, and the fat passes out of those cells into the circulation, it is oxidized. This produces chiefly water and carbonic acid gas. This oxidation takes place while it is being carried along in the circulating blood. This carbonic acid gas and water vapour are eliminated from the system as already explained.

When you take Figuroids, therefore, your extra fat simply passes from the adipose cells through their unbroken walls into the blood, and is there changed to water and Carbon Dioxide, and thus leaves the body.

This is the scientific, simple, natural explanation, and Figuroids is the only remedy which has the effect....

If then you are exceedingly stout and suffering from all the unpleasant symptoms resulting from that condition, if you find your weight excessive, if you suffer from heart palpitation, if you have redness of the face with annoying perspiration and shiny appearance of the nose and face, if the throat and bosom are altogether too stout, and if the lines of the figure have been lost, or if the abdomen has become too prominent, if Gout and Rheumatism make themselves manifest occasionally, and all the disagreeable and often dangerous symptoms of Obesity are apparent, you will know that in Figuroids you have a perfectly safe remedy, while if you suffer but slightly from Obesity and all the symptoms are less marked, you will also know that Figuroids furnish you with an effective, agreeable, and perfectly Safe cure....

When taking Figuroids it is not necessary to unduly restrict yourself in the matter of diet. You may eat and drink what you desire in reason. It would of course, be foolish to drink or eat excessively of fat or fattening foods.

In another enclosed circular the Company stated that:

They have decided to originate a No Cure No Payment system, and will refund the purchase money to any patient whose weight is not reduced by from two to six pounds per month whilst taking Figuroids.... This offer to refund purchase money is made on the understanding that the Figuroid Company's instructions are faithfully observed and the conditions of their offer complied with.

The directions on the label were as follows:

Each bottle contains an equal number of full doses (large tablet) and half doses (small tablet).

Take regularly one full dose (large tablet) dissolved in plain or soda water within 30 minutes after each of the first three meals on the first day. Next day take one half dose (small tablet) dissolved in plain or soda water within 30 minutes after each of the three meals. Third day take full doses again; and so continue alternating.

Although it is here clearly conveyed, without directly making the statement, that the large and small tablets only differ in being full doses and half doses respectively, examination showed their composition to be different, and it was necessary to analyse them separately.

Large Tablets.

The large tablets had an average weight of 58 grains; analysis showed them to contain an effervescing mixture of sodium bicarbonate and tartaric acid, in which the former was in excess, so that the resulting product was alkaline, together with sodium chloride (common salt), phenolphthalein, formamine (hexamethylene-tetramine), talc, and gum. The quantity of each of the ingredients was determined as accurately as possible, with the results given below; it will be noted that these quantities add up to 101·4 instead of 100, the reason being that the whole of the soda is for convenience represented as bicarbonate, whereas a portion of it had become converted to carbonate by loss of carbon dioxide.

In One Tablet. Sodium bicarbonate 62·0 per cent. 38·9 grains. Tartaric acid 22·6 " 13·1 " Sodium chloride 6·5 " 3·8 " Phenolphthalein 2·0 " 1·2 " Formamine 3·5 " 2·0 " Talc 2·8 " Gum about 2·0 "

Hexamethylene-tetramine or formamine, is perhaps better known by its trade names—urotropine, cystamin, urisol, etc.; it does not appear to have been described as of value for obesity.

Small Tablets.

The small tablets had an average weight of 34·3 grains. Analysis showed them to contain sodium bicarbonate and tartaric acid, but in this case the latter was in excess and the product acid; the other ingredients were sodium chloride, phenolphthalein, and talc. The results of quantitative determinations indicated the following formula (more carbon dioxide had been lost in this case; the figures add up to 108·5, the reason being that given above):

In One Tablet. Sodium bicarbonate 34·8 per cent. 11·9 grains. Tartaric acid 46·3 " 15·9 " Sodium chloride 22·8 " 7·6 " Phenolphthalein 1·6 " 0·5 grain. Talc 3·0 "

The estimated cost of the ingredients of the contents of a 2s. 9d. bottle is 1¾d.

FELL REDUCING TREATMENT.

In pushing this "treatment," advertised by an Association giving an address in London, the system of letters in series is resorted to, but a small package, containing 112 tablets, can be purchased for 6s. 6d.

An advertisement ran as follows:

FAT PEOPLE GIVEN FREE TREATMENT.

We have such marvellous records of reductions effected in hundreds of cases with the Fell Reducing Treatment, that we have decided, for a limited period only, to give free trial treatments.

7 LB. PER WEEK REDUCTION IS GUARANTEED, without dieting. Perfectly harmless, pleasant; easy and quick results. Send no money. Simply address the Fell Formula Association, 340, Century House, 205, Regent Street, London, W., enclosing stamp to pay postage, when a free supply in plain wrapper will be immediately forwarded.

A free supply was sent on application, accompanied by a letter and sundry circulars; other letters followed at intervals, and extracts from some of these will be given. They were printed in imitation of typewriting, with the name and address typed in, so as to give the appearance of being personal letters. It will be noted that when a customer has been attracted by the advertisement that "7 lb. per week reduction is guaranteed, without dieting," very much smaller claims are gradually substituted.

Esteemed Friend,

Your favour of recent date has received our careful attention, and we take pleasure in sending you a three days' trial of the Fell Reducing Treatment. Before taking it, weigh yourself, and then again in three days, on the same scales and in the same clothes, you will find you have lost some 3 lb. in weight.

An abnormal condition like corpulency requires that the antidote directly reaches the seat of the complaint, and by these Reducers the blood will be purified, and all the organs of the body restored to natural healthy action, while the germs of the disease will be entirely eradicated from the system, so that the superfluous fat, which will be removed will not return....

At the present stage of the disease in your case, we can positively assure you that under our treatment a marked improvement will begin at once, and continue steadily until a complete reduction in weight, with all the benefits to general health, is effected. Unlike most other methods of treatment, the action begins immediately and the sufferer feels better almost from the beginning, and it is with confidence that we advise you to begin a course of treatment with our Reducing Preparation at once.

Our regular terms and prices are 26s. for a case containing three 11s. boxes, whereby a saving of 7s. is effected.

If you take up the treatment in this manner you can be sure of having sufficient of the Tablets to take you through to a quick reduction. Single boxes of Tablets, however, are supplied at 11s. and smaller sizes at 6s. 6d. The 6s. 6d. box covers a ten days' treatment, while the 11s. boxes contain three times the quantity of the 6s. 6d.

This letter was not answered, but before long another was received which contained the following passages:

In sending you the sample of the "Fell" Preparation, we did so more to show the thorough nature of our treatment than from the expectation that material benefit would be realized from same. As you require to bring about a certain reduction you must necessarily undergo a certain course of treatment. A pound a day reduction results in many cases, and there is every reason to expect that such reduction can be effected in yours. A serious affliction such as obesity is not to be removed by any temporary remedy or with a few days' treatment....

Remember, a 26s. case contains sufficient treatment to reduce materially the most stubborn and long standing case, while an 11s. box contains three times the quantity of the 6s. 6d. box....

A supply was sent for and was accompanied by the following letter:

Dear Sir,

I have despatched to you the Tablets together with directions and instructions. I ask you to carefully observe same, and am confident if you do so, you will very soon see most beneficial results....

I am confident that you will be highly delighted with the splendid effects of the Tablets at the end of a few weeks if you follow carefully my instructions and are prompt and regular in taking the Tablets. I am sending you herewith printed instructions and rules for diet. You will note that our suggestion as to what you should eat, if strictly followed, will not work any hardship, and that you will never go hungry....

This letter, signed "_____ 'Adviser, Fell Formula Association,'" was accompanied by a printed circular giving rules as to diet, etc., and by a "symptom blank," to be filled up by the patient in order to obtain particulars of "the Fell System of Simple Muscular Movements for Reducing the Weight and Increasing the Strength, in combination with the 'Fell' Reducing Treatment"; it appears from the latter that particulars of these exercises are only supplied when the 26s. case is sent for.

A fourth letter dealt with generalities and recommended taking the reducing treatment in increased quantities, but after an interval a fifth was received, enclosing a booklet advocating the use of “the Century Thermal Bath Cabinet,” from which the following are extracts:

... We have strongly recommended the Home Turkish Bath that it may be used at least once a week as an adjunct to the Reducing Treatment; hence our affiliation to the “Century Thermal” Bath Cabinet, Ltd., whose home cabinet is built on such lines as to render it the best device extant for taking Hot Air or Vapour Baths.

... in any event, it were better to spend the required amount, for were the cost as much as £10 in all (it has but rarely exceeded that) the expense is out of all proportion to the ultimate benefit.

... with the Fell treatment no case of obesity, in either sex, can fail to be reduced if assisted with the regular use of the Hot Air Bath.

Booklets entitled _Corpulence or Obesity. Its causes, results, and successful treatment: The Treatment of Obesity by the “Fell” Reducing Treatment_: and _Make Muscle of your Fat_, were also sent at different times. The following extracts from two of these scarcely appear consistent:

A Guarantee to Reduce Weight.

It is not our purpose to indulge in empty talk only, or in unconsequential boasts. We are prepared to, and do, give a positive guarantee that the Fell Treatment, used in conjunction with the Muscular System, will reduce the fat of any person—provided our instructions are adhered to—in the space of a very few weeks.

Do We Guarantee?

We are frequently asked this question personally and by letter, and reply emphatically—No, we do not. To say Yes—would be illogical and certainly demoralising.

A guarantee that any medical remedy or curative will absolutely effect its stated purpose is misleading, deceptive, delusive, and is a trap to ensnare, not intelligent individuals, but the unwary, the unsophisticated, and those utterly unable to discriminate as to the merits or demerits of any so-called specific.

The dose was stated to be:

Nine tablets daily. Three taken three times a day before meals. They may be taken as pills or dissolved on the tongue.

The tablets had an average weight of 1 grain. Analysis showed them to contain 90·8 per cent. of milk sugar, 2·4 per cent. of greasy matter, which appeared to be a mixture of stearic acid and paraffin, evidently employed as a lubricant in making the tablets, and 6·8 per cent. of an extract which agreed well in its characters with extract of _Fucus vesiculosus_; its identity was further indicated by analysis of the ash. Each tablet would thus contain:

Extract of bladderwrack 0·07 grain. Milk sugar 0·91 ”

The estimated cost of the ingredients for 112 tablets is ¼d.

NELSON LLOYD SAFE REDUCING TREATMENT.

In this instance the bait of free trial for a fortnight is held out in the advertisements issued from an address in London; the following are extracts from one advertisement:

I myself am a member of a family many of whom died prematurely after much mental and physical suffering, arising from corpulence. While studying medicine for my degree, I saw the signs of the family complaint in myself. I naturally sought to avert what I for some time feared as being my hereditary fate. It was when I had almost given up hope that I discovered a cure for my condition, which all the time grew worse, in spite of my hopeful trials of all advertised and unadvertised remedies for stoutness. I at last gave up expecting a cure from other people. I experimented with my own thought-out remedies, and, happily, at last my perseverance—or, rather, my desperation—succeeded....

The result of several years’ study and experience has only served to make my treatment more and more successful....

I specially invite those who have tried other remedies for reducing weight without success to write me for:

I. A copy of my book, “The Scientific Treatment of Obesity” (just published, price 6d.), thoroughly deals with the subject in a popular, readable style....

II. Two photos of the lady referred to above, with her letter giving full particulars of her cure.

III. Everything required for a complete fourteen days’ free trial treatment.

I make no charge for all the above, but ask you to enclose sixpence (by postal order), just to cover the expenses of carriage, packing, and dispatch of parcel.

Application for the “Treatment” brought a box containing 42 tablets, a copy of the booklet mentioned above, and a letter and form for particulars. A few extracts will suffice to show what was claimed and the methods adopted.

From the booklet:

Different cases vary so much that the same treatment is never exactly suited to any two cases. Moreover, the treatment has to be modified as the patient progresses, the condition of the individual being periodically allowed for.... I wish to make it perfectly clear that not only do I offer every client the full benefit of practically a life-study of the whole subject of corpulence, but that I _guarantee_ to effect a cure of every case I take up.

There are no “ifs” and “buts” about my promises to my patients. I undertake to reduce corpulence by rational individual treatment in each and every case entrusted to me, and I undertake to promise (_sic_) that my treatment is in no way weakening, that it is permanent, and also that it has absolutely no ill effects.

From the first letter:

One of the Tablets should be taken after each of the three chief meals of the day for the next fortnight. I suggest that if convenient you weigh yourself before beginning the course, and again in fourteen days’ time, with the same scales and in the same clothes. You will find you have lost weight, while improving in your general condition.... My course of Treatment lasts a month except in unusual cases. The tablets I have sent you for the first fortnight will at once put a stop to the fat-forming habit of the body; these tablets are taken during the first fortnight in all cases, and while excellent results follow even in this brief period, they need to be followed up from the fifteenth day by additional and different remedies, adapted to each individual case.

In order to prepare this part of your Treatment I shall need to have before me full particulars of your case, which you can easily give me by filling up the Consultation Form enclosed herewith....

My fee for a month’s course of Treatment is one guinea, but you will see that I have given you credit for the first fortnight’s Treatment sent you herewith, because this is free in accordance with my offer through the Press. This means that by sending at once you can have one month’s complete treatment for half cost. To secure this concession you must, however, send me the Consultation Form filled up, and remittance for 10s. 6d. in time to continue your Treatment on the fifteenth day, and I must have at least three clear days in which to consider your case and prepare and post your Treatment to reach you in time.

The “Consultation Form” contained questions as to age, height, weight, chest and abdomen measurements, details of bodily condition, habits, and diet; this was filled up so as to represent an ordinary case of moderate obesity, and returned with 10s. 6d. In the next letter it was stated:

I am preparing your second fortnight’s treatment, and it will be forwarded in due course, but I feel I should like to take this opportunity of pointing out to you that there are special features about your case which, while not preventing the accomplishment of the improvement you desire, will, however, entail a little longer course of treatment than one month.

In my opinion your case requires a two months’ course of my treatment, at the end of which time the results will be all that you can desire. I thought it only right you should know this, and I would like you to tell me if you will take the full course my experience leads me to advise you.

My fee for the two months’ course is two guineas, but you have already standing to your credit the sum of one guinea, being one half-guinea allowed for first fortnight’s free trial, and the other half-guinea you have just sent me.

I should like you to take the full course my experience tells me is necessary for you, and if you now send me the one guinea balance, I will at once arrange for the supply of all the necessary remedies to you at the proper intervals.

The second fortnight's treatment consisted of "special tablets" and a liquid; these were accompanied by a further letter, a diet table, and a report form, to be filled in and returned after 10 days.

The three kinds of medicine were examined with results as follows:

The preliminary tablets.—There were 42 in the box, and the directions were to take one three times a day after meals.

They were sugar-coated and coloured red externally; after removal of the coating, they had an average weight of 4·7 grains. Analysis showed them to consist principally of substances of extract nature, together with an amount of liquorice fibre representing about 20 per cent. of powdered liquorice; iodine was present in organic combination, and a nitrogenous substance; the amount of nitrogen was 0·51 per cent., representing 3·2 per cent. of proteid; no tissue of thyroid gland was present, and the nitrogenous material was probably contained in an extract of this substance. The remainder possessed the general characters of extract of _Fucus vesiculosus_, and its identity was also indicated by analysis of the ash; some gum was also present, and some indication was obtained of another substance also, which, however, possessed no important characters, and was probably also of the nature of excipient. The formula indicated by the results was thus:

Extract of bladderwrack 2·5 grains. Proteid of thyroid gland 0·15 grain. Powdered liquorice 0·9 " Excipient and moisture, etc. q.s. In one tablet.

The "special" tablets.—There were 33 of these in a box; the directions were to take one after the mid-day and one after the evening meal. They were sugar-coated but not coloured. After removal of the coating, they had an average weight of 4·6 grains. Analysis showed their composition to agree qualitatively with that of the preliminary tablets, but the nitrogenous material and the liquorice were present in somewhat larger amounts. The following formula was indicated by the results:

Extract of bladderwrack 2·5 grains. Proteid of thyroid gland 0·19 grain. Powdered liquorice 1·4 " Excipient and moisture, etc. q.s. In one tablet.

The liquid.—Two fluid ounces were supplied, the directions being to take 30 drops in a wineglassful of cold water the last thing at night before retiring and on rising in the morning. Analysis showed this to contain alcohol, glycerine, nitrogenous matter, a little iodine in organic combination, and substances of extract nature; the character of the extract and the composition of the ash again pointed to its being derived from _Fucus vesiculosus_; the amount of nitrogen was determined and the equivalent amount of proteid matter calculated; the alcohol and glycerine were also determined quantitatively: the amount of extract of bladderwrack could only be arrived at by difference, supported by the probability that the alcohol was all, or nearly all, added in the form of the fluid extract of this drug, and the figure can therefore only be given with reservation; there were also indications of some small amount of flavouring and colouring matter having been added. The approximate formula appeared to be:

Proteid of thyroid gland 0·3 part. Liquid extract of bladderwrack 32 fluid parts. Glycerine 12 " In 100 fluid parts.

The amount of thyroid actually represented by the nitrogenous matter found in these three preparations was too uncertain for an estimate of the cost price to be of value.

CORPULIN, AND DALLOFF'S TEA "CONTRE L'OBESITÉ" GRAZIANA ZEHRKUR.

Of the German preparations examined by Dr. Zernik two contain bladderwrack. One called Corpulin contains also tamarind and cascara sagrada. The other, Dalloff's Tea "Contre l'Obesité," as to which the advertisers assert that "regular use leads to the removal of superfluous adipose tissue and the person becomes healthy and attains old age" was found to consist of a mixture of the leaves of senna, bearberry (_Uvœ ursi_) and lavender, and anthylla flowers. Any action it may have depends probably on the senna leaves. It is sold in boxes costing 7s. 6d. or 4s. 6d.; the smaller box contains 80 grammes, or nearly 3 ounces of the powder.

Graziana Reducing Treatment (Zehrkur) is sent out in parcels costing 3s. Each contains a packet of a greyish-brown powder, a box of 40 starch capsules, each containing 0·2 gramme of a light brown finely-divided powder, and a box of 86 pills, each weighing 0·22 gramme. The chief ingredient of each of the preparations is powdered _Fucus_. The pills contain some substance yielding emodin, the purgative principle, or one of the purgative principles, of aloes, rhubarb, buckthorn, and senna, and also some sulphates and chlorides.

CHAPTER X.

SKIN DISEASES.

Proprietary articles for the cure of eczema and other skin affections include several which are as widely advertised as any nostrums of any kind. Some of them are at first offered at the comparatively low price of 1s. 1½d.; but in almost every case the further information supplied on application shows that what is really recommended is a “treatment,” including an ointment or other application, a special soap, and a medicine to be taken internally, and often also a dusting powder, and occasionally other articles. The importance of persisting in the treatment is strongly emphasised, with the result that anyone who once lays out 1s. 1½d. is likely to be drawn into spending quite a considerable sum. Only a few out of the long list which might be made of these articles have been analysed, but the results throw sufficient light on the general nature of the whole class. The most striking point about them is perhaps the extremely commonplace nature of the drugs selected, although the vendors in some instances would have the buyer believe that the preparation sold is the result of years of patient experiment.

ANTEXEMA.

A Company with an address in London advertises for sale a bottle, price 1s. 1½d., containing a little less than 1½ ounces, but the “Antexema Treatment” includes Antexema, Antexema Soap, and Antexema Granules (to be taken internally). On a handbill enclosed with the bottle it was stated that:

In most cases “Antexema” will by itself effect a cure, but the permanence of this is assured by the continued use of a suitable soap, and the cleansing and purifying action of “Antexema Granules” on the blood.

A booklet on “Skin Troubles” was also enclosed, containing some “before” and “after” illustrations, but they could hardly be expected to convince anyone; directions were given in this for the course to be pursued in a variety of disorders, including such “skin troubles” as in-growing toenails, lupus, piles, ulcers, etc. Incidentally, twelve other preparations made by the same Company, in addition to the three named above, were recommended.

On the outer package it was stated that:

“Antexema” is the most efficacious remedy known for the relief of all inflamed conditions of the skin. Its beneficial effects are not confined to the curing of Eczema, Psoriasis, Nettlerash, Erysipelas, Boils, and other serious troubles, but it is also by far the best remedy for Cuts, Burns, Sores, Bruises, Chilblains, Blisters, Insect bites, and every variety of trouble to which the skin is liable.

Only “Antexema” itself was analysed. It consisted of an emulsion, with more or less of a watery layer below it. The directions for use were:

Shake the bottle well, and, if necessary, stir up the contents until a milky substance is formed. Then gently rub “Antexema” into the parts affected until dry, and if the case is a severe one it should be applied as often as possible. “Antexema” is odourless, non-poisonous, and invisible when rubbed on the skin, and it instantly allays irritation. Do not wash any weeping or inflamed surface until healed, and, if possible, avoid dressings and coverings.

Analysis showed it to consist of:

Soft paraffin 35·4 per cent. Boric acid 1·5 ” Gummy matter 12·4 ” Water 50·7 ”

The gum resembled in some respects a mixture of acacia and tragacanth, but could not be exactly identified.

The estimated cost of the ingredients of 1½ ounces is two-thirds of a penny.

PACIDERMA PREPARATIONS.

These preparations are advertised as follows from an address in London:

New Cure for Eczema.—A victim who was cured after 5 years’ intense suffering will gladly send to all readers of the _Christian Herald_ full particulars (free) of an inexpensive guaranteed cure for Eczema, Bad Legs, Sore Hands and all Skin Eruptions, on receipt of stamped addressed envelope.—Write to A. Paciderma.

An application to the address given brought a typed letter apparently produced on a multiple copy machine, from “Paciderma. Manageress, Mrs. E. Avice,” from which the following extracts are taken:

“Paciderma” ... consists of three preparations (in one package), one for internal use and two for external use. Both internal and external Remedies are absolutely necessary to eradicate the disease.... The price is most moderate, namely 6s. and postage 3d. for the package containing the three preparations for thirty days’ full treatment. In conclusion I would point out to you that these Remedies have met with a world-wide success, even in the worst forms of these terrible complaints, and are in fact so wonderfully successful that they are

GUARANTEED EFFICACIOUS IN EVERY CASE

no matter what has previously been tried and failed.... Be sure to fill up the Order Form which I am enclosing you as carefully and accurately as you can so that I may be able to give your case my fullest attention and consideration.

This letter was accompanied by a booklet entitled “Eczema and how to Cure it,” and by an order form with spaces for name, address, date, and the following further particulars:

Age; sex; occupation; how long been suffering? where the complaint is located; are the spots or wounds dry? is there any sticky discharge? are your bowels constipated? do you suffer from piles? do you suffer from indigestion? do you suffer from rheumatism or gout? Do you suffer from any other complaint?

This form, filled up with the details of an imaginary case, was sent with a postal order for the requisite amount. A case of “Paciderma” preparations was at once received, and needless to say there was no evidence of their having been modified in any way in consequence of the “fullest attention and consideration” given to the particulars supplied. The preparations were accompanied by a further letter, typed like the first, from which the following is extracted:

One case of the remedies is generally sufficient to effect a cure, and I trust that it may be so in your case, but if the disease has been in the system for years it has got a firm hold, and naturally takes longer to eradicate; therefore, if this case of remedies should not cure you, you must lose no time in writing for a further supply so that no time may be lost between. You must avoid anything likely to irritate the skin, and be especially careful as to the soap you use, as many soaps are most injurious, being quite sufficient in themselves to cause an eruption. I should recommend you to use “Paciderma Skin Soap” to wash yourself with, as it is absolutely pure, and will keep your skin smooth and healthy.

After an interval a further letter was received, which ran as follows:

Dear Sir,—I have been expecting to hear from you as to how the treatment I sent you some time ago has affected you. I sincerely trust that you have derived benefit from it. As I think I told you before, some cases are naturally much more difficult to cure than others, and take longer time, as in most cases the disease has been for years getting a firm hold on the system, and cannot, therefore, be eradicated in a few days.

I assure you I should be the last to induce you to spend money, unless I honestly thought and believed that the treatment would benefit you. I have been a fellow sufferer myself, and know what it did for me by persevering after everything else had failed. If, therefore, you are not yet cured, I think it is only my duty to strongly urge you to persevere with the treatment, and if you hesitate to do so owing to the money being a consideration to you, I am willing to meet you as far as I possibly can, and will send you the complete 6s. 3d. case for 4s. 6d. post free, which is just cost price, or I will send you the Blood Wafers for 2s. 2d. per box post free instead of 2s. 10d., or the Crème for 2s. 2d. post free instead of 2s. 10d., or the Powder for 7d. instead of 9d. post free.

I am offering you this very great reduction in price as I am most anxious that you should be cured, as I am quite certain that you will be if you persevere steadily.

Do not be afraid of troubling me by writing me fully as to how the treatment has affected you, as I can assure you that I am quite as anxious to cure you as you yourself are to be cured, and I take a special interest in your case.

Trusting soon to hear from you.

Yours truly, E. AVICE.

The booklet already referred to contained a sworn statement by Mrs. Avice detailing her own sufferings and cure, the latter being due to “a dear old friend, an M.D.” Further paragraphs, not in the sworn statement, were as follows:

It remained for my old friend, the Doctor, to whose discoveries I owe my cure, to find the only certain remedy for this dread complaint. For years he studied and searched to find a cure for that curse of hot climates, the “prickly heat,” a very distressing form of Eczema which is very prevalent in warm countries, and which few Europeans escape. At last his perseverance was rewarded, and the long sought for Remedy found and used with the greatest success both abroad and after his return to England. Since his death I have still further improved on and perfected his ideas, and have evolved my now well-known “Paciderma,” which has met with the most startling success in every case in which it has been tried....

Paciderma cures all skin troubles without exception, all pimples, blotches, sores and eruptions of every kind, in sufferers of every age, from the infant at the breast to the old and infirm man or woman who has reached or passed the allotted span of three score years and ten.

It is absolutely the only cure for Eczema.

The following are the results of the examination of the remedies evolved after so much study and research and perfected and improved:

Paciderma Crème.—Price 2s. 9d. per box, holding nearly 4 ounces. Directions for use:

Apply the Crème to the parts affected with the finger, or spread on lint or soft linen, and bandage.

The Crème consisted of a fairly stiff ointment, which on analysis gave results corresponding to the following formula:

Zinc oxide 25·6 per cent. Calcium carbonate 2·7 ” ” sulphate 15·8 ” Boric acid 15·9 ” Basis 58·7 ”

The basis consisted of soft paraffin, apparently with a small proportion of a saponifiable oil, such as olive oil.

The estimated cost of the ingredients for 4 ounces is 1½d.

Paciderma Powder.—Price 9d. per box, containing about 3 ounces. The directions ran:

Allays all itching and irritation, and should be applied freely and frequently to the affected parts, in fact whenever they itch or irritate.

Analysis showed the composition to be:

Maize starch 54 per cent. Boric acid 14 ” Insoluble mineral matter 19 ” Moisture 13 ”

The insoluble mineral matter contained alumina, magnesia, and silica, corresponding to a mixture of talc and kaolin; this composition also agreed with all its other properties.

The estimated cost of ingredients for 3 ounces is ¾d.

Paciderma Blood Wafers.—Price 2s. 9d. per box of thirty.

Directions. One to be taken every night at bedtime.

The “wafers” consisted of cachets, each containing about 8½ grains of a powder, the composition of which was indicated by analysis to be:

Sodium bicarbonate 59 per cent. Precipitated sulphur 37 ” Powdered ginger 3 ” Aloin 1 ”

The ginger and aloin could only be estimated approximately.

The estimated cost of the ingredients for 30 wafers is one-fifth of a penny.

CUTICURA REMEDIES.

The remedies are stated to be prepared by a Drug and Chemical Corporation in the U.S.A.

The “system,” which has been very widely advertised, consists of Cuticura (Ointment), Cuticura Soap, and Cuticura Resolvent (liquid or pills); the ointment and the resolvent liquid were taken for analysis.

A booklet was enclosed in each package, containing, with other matter, directions for the use of the remedies in fourteen languages; from it the following extracts are taken:

In the treatment of torturing, disfiguring, itching, scaly, crusted, pimply, blotchy, and scrofulous humours of the skin, scalp, and blood, with loss of hair, the Cuticura Remedies have been wonderfully successful. Even the most obstinate of constitutional humours, such as bad blood, scrofula, inherited and contagious humours, with loss of hair, glandular swellings, ulcerous patches in the throat and mouth, sore eyes, copper-coloured blotches, as well as boils, carbuncles, sties, ulcers, scrofulous rheumatism, and most humours arising from an impure or impoverished condition of the blood, yield to the CUTICURA SYSTEM OF TREATMENT in the majority of cases, when the usual remedies fail.... Parents are assured that these Remedies are composed of the purest and sweetest ingredients known to modern pharmacy, and may be used on the youngest infants with complete satisfaction.

Cuticura Ointment.—Price 2s. 6d. per box, containing 1¾ ounces.

Directions.... Cuticura Ointment may be applied to any part of the surface of the body by direct application with the finger, the palm of the hand, or spread on cotton, linen, or absorbent cotton, and covered with a light bandage, or by any means by which a remedy of this consistence would be used.

... in rare instances of individual tendency to acute eczema, acne, acne rosacea, erysipelas, and other highly inflammatory conditions, especially those affecting the face, it may act as an irritant, and hence those using it must observe what has been said in the foregoing directions in order that they may exercise judgment as to whether to continue it or not, should any unfavourable symptom present itself.

Examination of the ointment showed the absence of all metallic compounds, also of alkaloids or other active principles, and of saponifiable fat. It consisted of a mixture of hard and soft paraffins, slightly perfumed with rose, and coloured green. The chief green colouring matter present appeared to be an aniline dye, and a mixture of paraffins, coloured with a trace of malachite green and a little chlorophyll, agreed very closely with it in its properties. No other ingredient could be discovered.

The estimated cost of the ingredients of 1¾ ounces is ¾d.

Cuticura Resolvent.—Price 2s. 6d. per bottle, containing 6½ fluid ounces.

In the pamphlet quoted above it is stated:

Cuticura Resolvent is alterative, antiseptic, tonic, digestive, and aperient, and is confidently believed to be superior to other preparations for purifying the system of humours of the skin, scalp, and blood, with loss of hair. CUTICURA RESOLVENT is prepared in accordance with the most advanced pharmaceutical and therapeutical knowledge from medicinal agents of ascertained purity and potency, and while in the highest degree effective, commends itself to delicate, sensitive, and refined people, especially women, because of its pure, sweet, and gentle action.... It is believed to be one of the most successful of blood-purifying and strengthening medicines for children in all conditions which point to inherited impurities and weaknesses, and may be taken on the first appearance of glandular swellings, ulcers, sores, especially on the neck, pallor, weakness, and delicate, frail conditions, with every hope of success.

DIRECTIONS.—Adult dose, two teaspoonfuls three times a day; for children over ten years of age and delicate females, one teaspoonful; for children from five to ten years of age, one half of a teaspoonful; for children two to five years of age, 15 drops; from one to two years, 10 drops. To be taken three times a day, immediately after each meal.

Analysis showed the composition of the mixture to be:

Potassium iodide 17 grains. Sugar and glucose 486 ” Extractive 8 ” Alcohol 10 fluid drachms. Water to 6½ fluid ounces.

No alkaloidal substance was present; the extractive gave a slight indication of the presence of a preparation of rhubarb; all other drugs with well-marked characters were absent.

ZAM-BUK.

This ointment is sold by a London Company in a box, containing three-fifths of an ounce, price 1s. 1½d.; a Zam-Buk soap is also recommended for use as part of the treatment. In a circular enclosed in the package it was related how:

Certain medicinal plants were taken, and from them were extracted gums and juices possessing considerable healing and curative power. Costly experiments at last secured the right blending of these juices; and to the final product, a preparation virtually capable of growing new and healthy skin, the name of Zam-Buk was given....

Zam-Buk practically contains those substances which Nature has intended for the use of man ever since she bequeathed to him the instinct to rub a place that hurts....

Zam-Buk has proved itself to be unequalled for Cuts, Bruises, Burns, Scalds, Abrasions, Festering Sores, Poisoned Wounds, Lacerated Wounds, Old Wounds, Sprains, Strains, Swellings, Dog Bites, Cat Scratches, Obstinate Sores, Chafings, Itch (Scabies), Stings from Hornets, Bees, Wasps, Centipedes, and Spiders; Running Sores, Ulcers, Ringworm, Eczema (acute or chronic form), Psoriasis (tetter), Pimples, Acne, Abscesses, Boils, Carbuncles, Scrofula, Cramp, Barber's Itch, Heat Rashes, Sunburn, Freckles, Blotches, Blackheads, Scalp Irritations Scurf or Dandruff, and other Scalp Sores; Colds, Chills, Raw Chapped Hands, Sore Lips, Raw Chin after Shaving; Inflamed Patches, Sore Nipples, Glandular Swellings, Swollen Knees, Bad Legs, Blind and Bleeding Piles, Cold-Sores, Sore Backs, Diseased or Weak Ankles, Sore and Aching Feet, Perspiring Feet, Chilblains, Soft Corns, Saltwater Sores. Rubbed well into the part affected, Zam-Buk gives great relief from Rheumatism, Lumbago, Neuralgia, Sciatica, Toothache, and allays all kinds of Inflammation, Itching, and Irritation.

The directions on the box were:

For Bruises, Cuts, Sores, Sprains, Open Wounds, Sore Breasts, Inflamed Patches, Ulcers, Eczema and Piles; first cleanse the parts with pure water and then apply Zam-Buk direct or on a piece of clean lint. For Burns, Scalds, etc., rub Zam-Buk lightly over the injured part and cover same as soon as possible in order to exclude the air. To use Zam-Buk as an Embrocation rub it in well, both into the muscles and tendons, when the healing, stimulating and strengthening ingredients in Zam-Buk will be absorbed into the system.

Analysis showed its composition to be:

Oil of eucalyptus 14 per cent. (approximately). Pale resin (colophony) 20 " " Soft paraffin 55 " " Hard paraffin 11 " " Green colouring matter a trace.

An ointment prepared in accordance with this formula and tinted with chlorophyll agreed in all respects with the original.

The estimated cost of the ingredients for three-fifths of an ounce is ¼d.

ZIP OINTMENT.

This is supplied by a Company giving an address in a London suburb in box containing rather less than an ounce (0·85 ounce) at the price of 1s. 1½d.

On a circular enclosed with the box this ointment was described as a "cure for Eczema, Ringworm, Psoriasis." It was also stated that:

Zip is the product of many years' experience and trials, and will be found the best and most reliable remedy for the above troublesome complaints.

The directions given on the box were:

Wash well the parts with the Zip Skin Soap, and apply Zip night and morning.

Analysis showed the composition of the ointment to be:

Calomel 2·1 parts. Lead acetate 1·0 part. " oleate 2·5 parts. Oil (probably olive) 2 " Glycerine 5 " Creosote A trace. Oil of lemon grass Sufficient to perfume. Paraffin ointment To 100 parts.

The estimated cost of the ingredients for 0·85 ounce is ½d.

The following are quoted from Dr. Zernik's notes on some of the skin remedies most advertised in Germany.

CRÈME EKZEMIN.

Crème Ekzemin, advertised as a cure for almost all diseases of the skin, including psoriasis, is a mixture of precipitated sulphur and a semi-fluid fatty mass, coloured red. The tube contains 75 grammes, and costs 5s. 2½d.

PHEUN SKIN PASTE.

Pheun Skin Paste, according to the vendors, possesses marvellous properties, and when applied to the skin it not only removes all the dirt but kills all the bacteria, even when situated in the deeper layers, and it is recommended as a cure for all forms of skin diseases. Zernik, on analysis, found it to contain 31 per cent. of soft paraffin, 5 per cent. of water, 2 per cent. of soap, and 10 per cent. of a dry substance yielding slimy material.

JUNIPER BEAUTY CREAM AND JUNIPER BEAUTY SOAP.

It may be worth while to add that Zernik says of a certain “Juniper Beauty Cream,” sold in Berlin, that it is a water-containing ointment, perfumed with oil of bergamot, containing 5 per cent. of white precipitate (ammoniated mercury) and 11 per cent. of salicylic acid. It seems to be intended for the face, but looking to the large proportion of salicylic acid it contains, it might, perhaps, be more appropriate for use as a corn plaster.

RINO CURATIVE OINTMENT.

Rino Curative Ointment, advertised as containing naphthalan, Peru balsam, chrysarobin, etc., was found by Zernik to consist of turpentine, oil of cade, 1 per cent. of boric acid, 6 or 7 per cent. of yolk of egg and an indifferent vehicle,

CHAPTER XI.

MEDICINES FOR BALDNESS.

During recent years the number of preparations put forward for the cure of baldness has been increased by a new class, those, namely, which are not applied locally but taken internally. The principal ingredient in all seems to be the dried colouring matter of the blood of warm-blooded animals—haemoglobin. The most widely advertised of them is sold under the name of “Capsuloids.”

CAPSULOIDS.

The price was 2s. 3d. for a box containing 36 capsuloids.

On the outer package it was stated that:

Our special process used in making Capsuloids is never used and never has been used outside our Laboratory. It is known only to the Capsuloid Company, Ltd., and has never at any time been communicated to any other person or firm. This material is then enclosed in little pear-shaped gelatine capsules which are made of the finest and purest gelatine. As a result of our special process, Capsuloids have that particular and remarkable effect upon the hair through the medium of the blood which is so well and widely known. There is no other preparation which possesses anything like the same effect.

Capsuloids not only cause the death of those harmful germs which we have proved to be the cause of falling out and prematurely grey hair, but they also restore the injured growing cells of the hair roots, and nourish them, and cause them to multiply so that the roots become firm and grow rapidly, producing thick and luxuriant hair, and where there has been premature greyness, it is also cured. Recent scientific investigation has definitely proved this, and has demonstrated that hair cannot be made to grow by using external preparations.

Directions. To stop falling out of the hair and to restore the colour to prematurely grey hair, adults should take two, or in very severe cases three, capsuloids before eating or with the first part of each meal, three times daily. The doses for younger persons is one or two with each meal. Capsuloids never cause constipation or indigestion, nor do they in any way upset the stomach, or any part of the system.

A booklet of 20 pages was enclosed in the package, in which the above statements were repeated and further elaborated with the aid of a diagram of the root of a hair, with blood-vessels, oil gland, “growing cells containing harmful germs,” etc.

The capsuloids were elongated gelatine capsules containing a dark material, the average contents of one weighing 3·4 grains. The material yielded 32 per cent. to a solvent suitable for extracting fats, and this portion proved to be a mixture of about equal parts of a neutral oil and a fatty acid, agreeing in their characters with olive oil and oleic acid, respectively. Extraction of the residue with alcohol then removed 10 per cent. of an aromatic balsamic substance, generally resembling Peruvian balsam, but lighter in colour; a mixture of equal parts of Peruvian balsam and purified storax gave a substance practically identical. The residue, insoluble in both solvents, was a red-brown powder, which was found by its characters to be dried haemoglobin. Careful search was made for arsenic, alkaloids, and other ingredients, but nothing else was detected. The results indicated the following formula for the contents of the capsules:

Haemoglobin 1·97 grain. Olive oil } Oleic acid } of each 0·54 ”

Balsam of Peru } Purified storax } of each 0·17 ” In one capsule.

The estimated cost of materials for the contents of 36 capsules is 1d.

Other dealers have paid the company the sincere compliment of imitation, and various similar articles appear to be largely sold. The following particulars are taken from price lists and advertisements intended for retail chemists; as haemoglobin is referred to as the principal constituent in each case, they were not submitted to analysis.

CAPSULATED HAEMOGLOBIN OVALS FOR THE HAIR.

“Capsulated Haemoglobin Ovals for the Hair. Contain 2½ grains of Pure Haemoglobin.”

They were supplied by a firm in a south country seaside town, labelled with name and address of the retailer. The wholesale price quoted was for tubes of 25, 4s. per dozen.

HAEMOGLOBIN HAIR CAPSULES.

“Capsules for the Hair. When falling out or turning prematurely grey, these capsules by enriching the blood make the hair glossy, luxuriant, and full of vitality.”

These were not described on the package as containing haemoglobin, but were quoted in the price list as “Haemoglobin Hair Capsules.” They were supplied by a company in a seaside town. “Store price, 1s. 6d.” Wholesale price, 7s. per dozen packages.

SOLUBLE CAPSULES OF HAEMOGLOBIN.

“Soluble Capsules of Haemoglobin. A natural hair food. Produces Healthy, Strong, and Luxuriant Hair.”

The wholesale price of these, supplied by a London firm, was for boxes of 36, 5s. 9d. per dozen.

CHAPTER XII.

CANCER REMEDIES.

A very slight acquaintance with the advertisements of quack medicines is enough to show that a knowledge of the causes of the disease for which a cure is promised is in no wise necessary for the composition of either the medicine or the advertisement, in fact, it is impossible to believe that the extravagant claims and absurd statements made could be put forward by persons having any knowledge of disease. It is no matter for surprise, therefore, that in the case of the least understood and least successfully combated of diseases many proprietary “remedies” are put forward. A considerable number of these articles have been received and the alleged claims tested at the laboratories of the Imperial Cancer Research Fund; specimens of a few of these were obtained and submitted to analysis, and some notes on their composition cannot fail to be of interest to members of the medical profession, who will probably from time to time have to treat sufferers from cancer who have been induced to buy one or other of these preparations.

As was to be expected, the articles examined have little or nothing in common. In the case of diseases for which the ordinary treatment involves the use of certain specific drugs, proprietary medicines are usually merely varying compounds of those drugs; thus, of the advertised cures for epilepsy, analyses of which are given in the next chapter, the essential ingredient in all but one is an alkaline bromide. But in cancer the would-be maker of a proprietary “cure” has no such accepted treatment to guide him, or to

restrict the free range of his fancy in selection of ingredients; it is probable that some of the “remedies” here described were inspired by the fact that some apparent improvement followed their fortuitous use in some cases, _post hoc_ having been assumed to mean _propter hoc_; the first to be described, however, can hardly rest even on this basis.

It is a colourless liquid, containing a trace of sediment; the odour is that of alcohol, though very slightly vinous. Fractional distillation showed the presence of about 40 per cent. of alcohol; on complete evaporation, a trace (0·02 per cent.) of dry residue was left. This residue was free from any alkaloid, and its behaviour with reagents gave no indication of any other active principle; it agreed in character with the “extractive” found in spirit that has been kept in a wine-cask. After removing the alcohol, the liquid was perfectly tasteless. This “remedy” is thus very simple in nature, consisting merely of diluted and slightly impure alcohol. Its composition brings to mind the analysis published some years ago of a so-called electric fluid, or “electricity,” for the cure of cancer, which was taken up by a certain well-known journalist and boomed by him in the pages of the review which he edited; many marvellous cures were ascribed to it, but examination showed that although it was sold at several shillings per fluid ounce, it consisted of plain water. Notwithstanding the exposure, the article is at present quoted in wholesale lists, and is therefore presumably still in demand. The cost of the “medicine” we are now dealing with is of course considerably greater than the cost of plain water, but this fact will be but small consolation to the victim who derives as little benefit from the one as from the other.

The next article analysed was a blue fluid containing a considerable blue sediment, and smelling fairly strongly of terebene. The chief ingredient was found to be a blue dye stuff of the oxazine or thiazine group, much resembling methylene blue (which is the only member of these groups ordinarily used in medicine), but differing from it in solubility and in its behaviour with certain reagents. This constituted the greater part of the sediment, and a portion of the dye was also in solution. The liquid further contained a dissolved gum and a trace of terebene; these, with a little magnesium carbonate, were all the ingredients present. No trace of any alkaloid was found, and the solvent was water. The gum showed no difference from ordinary acacia gum, and was probably added to suspend the undissolved dye stuff. Water dissolves very little terebene, and no more of the latter was present than could be dissolved by the water; it was probably employed to give an aromatic taste and smell, and the magnesia was doubtless used to subdivide the terebene in the manner commonly followed by pharmacists when dissolving essential oils in water. It thus appears that the essential ingredient of this medicine is the blue dye stuff; it is possible that this has been used as methylene blue, since the articles sent out under the same name by different dye manufacturers often differ in composition; but, as already stated, it is not identical with the methylene blue usually met with. The total solids in the mixture, after shaking up the sediment, amounted to 13·2 per cent., of which the dye stuff constituted something like one-half.

A third preparation was a brown liquid of syrupy consistence found to consist of wood tar. It was a much purer product than ordinary Stockholm tar, and its peculiar odour indicated that it was derived, at least in great part, from the birch; no other ingredient could be found. This article came from Sphakia, Crete; the label bore no directions for its use, leaving it uncertain whether it was intended for internal or external use, but the latter appears the more probable.

The remaining articles are clearly intended for external application; the first of these consisted of a plaster mass, in the half-pound sticks in which such masses are usually supplied. Analysis showed the principal ingredient to be lead oleate, with a little stearate, and small quantities of resin and soap. These are the ingredients of the resin and the soap plasters of the _British Pharmacopœia_, and the proportion of soap present showed the specimen under examination to be emplastrum resinae.

The next preparation was an ointment of Dutch origin. It contained large quantities of ammonium alum and zinc sulphate, with a little sodium sulphate, made up into a stiff ointment with a basis consisting of beeswax, soft paraffin, oil, and resin. The quantities of the salts were approximately:

Alum 27 per cent. Zinc sulphate 37 ” Sodium sulphate 8 ”

The presence of so large a proportion of mineral salts, of course, leaves very little tenacity in the ointment; particles of the white salts were easily visible to the eye, and the effect of applying the preparation must be practically the same as if the dry salts were rubbed on the skin except that the basis would, of course, act as a lubricant in the rubbing.

The last of these preparations was another ointment; the mineral ingredients in this case, however, were in organic combination. This ointment contained copper oleate and aluminium oleate with a basis of lard and a little resin. The proportions of the active ingredients were approximately:

Copper oleate 15 per cent. Aluminium oleate 35 ”

No alkaloid or other active principle was found.

A bottle of lotion for cancer and other affections, obtained in the ordinary way through a dealer, was examined. The label commences with the statement that the lotion “cures cancerous or malignant sores”; then follows a list of other diseases, with the addition, “even cases that have been under the treatment of doctors and at infirmaries for years.” Analysis showed the composition of the lotion to be substantially as follows:—

Zinc sulphate 92 grains Carbolic acid (pure phenol) 1·2 oz. Glycerine 1·8 fl. oz. Cochineal solution sufficient to give a deep red colour. Water to 3·3 fl. oz.

This quantity is contained in a bottle costing 4s. 6d.; the directions are to add the whole contents to 1½ pints of water, which is to be applied to the diseased parts for about five minutes two or three times a day.

Another pretended “cure” for this disease was supplied from an address in Croydon, by a person who described himself as a retired Government analytical chemist. The bottle did not bear an Inland Revenue stamp. The vendor seems to prefer to see and examine the patients. In one such case he was paid 3 guineas, and asked for more, as it was, he said, a complicated case. The directions given were “two tablespoonfuls should be taken three times a day.” Analysis of this liquid showed the presence of ferric chloride, and traces of hydrochloric acid and alcohol, and nothing else except water; the alcohol indicates that the tincture of perchloride of iron, and not the liquor, was employed; determination of the amounts of iron and chlorine present showed that 6 fluid ounces of the mixture contained 5·7 fluid drachms of the tincture.

A few years ago a good deal was heard of the wonderful cures said to be achieved by two persons who resided at Cardigan. A great deal of secrecy was observed, but it was known that a fluid was applied to the surface of the cancerous tumour. The treatment, it was stated, began with prayer, and exhortations to the patient to trust in the Almighty; the lotion or oil, which was said to be made entirely from herbs and to contain no mineral caustic, was then painted on with a brush. Unlike other empirics who profess to remove the “roots” which the knife leaves behind, these Welsh practitioners asserted that their remedy made the “roots” shrink into the original growth which then fell off like a ripe apple from a tree. The practice seemed to be to require the patient to attend daily to have the local application made for periods extending over several months. Eventually, in some cases, a mass of dried, heaped-up crusts formed, and when this became detached it was put into a bottle and given to the patient who was told that it was the cancer extracted by the treatment. In one case which was enquired into, this bottle cancer was submitted to microscopical examination; it was found to consist of crusts formed of sloughing parts of the skin and inflammatory exudation, the whole being such a mass as might be produced by the use of an escharotic. The crusts when submitted to chemical analysis were found to contain zinc chloride in considerable amount, together with a very appreciable quantity of an insoluble compound of lead. A healing oil was also supplied to help the cancer falling off, and this when chemically examined was found to contain 27 per cent. of oil of turpentine, the remainder consisting principally of an ordinary saponifiable oil, probably cotton-seed or olive oil. In addition there was a considerable amount of deposit which proved to consist almost wholly of barium sulphate, a very insoluble salt, used, under the name of permanent white, by watercolour artists. It would seem, therefore, that the statement that the applications contained no mineral caustic was inaccurate. In other patients the effect of this Cardigan treatment was more destructive. In the case of one woman who had been informed that the cancer had been cured and that she only required some tonic medicine to complete the cure, the surgeon who was called to her when she was _in extremis_ has said that he never beheld anything like it in his life; the whole breast was a necrosing mass, black and stinking, the ulcers extending up to the collar-bone and down to the margin of the ribs and across the middle line; the hand could have been inserted under the margin of the dead part all round. Some unfortunate patients persevered with the treatment although suffering pain described as excruciating.

Caustics are, in fact, the weapon of the quack, and although they may have a legitimate sphere in surgery, it is very limited; zinc chloride, for instance, has occasionally been used in a strong solution or paste as a caustic under special circumstances. Although portions of a tumour may be removed by caustic application, it is impossible to eradicate the whole in this way, as the cancerous process is extending into adjacent parts. The formula of the quack—“cancer treated without the knife”—appeals with great force to the public who do not know the terrible long-drawn-out agony which those treated with caustics have to undergo. Of this a vivid description was given by a well-known naturalist, the father of a distinguished man of letters, in a little book in which he related the suffering of his own wife; she was treated by an American cancer-curer by caustics. The process of “cure” lasted several months, and the result may be summed up in the statement that “suffering never ceased from the beginning of the operation till her spirit was freed from the worn-out body.”

CHAPTER XIII.

REMEDIES FOR EPILEPSY.

The nostrums which appear to be most advertised at the present time for the treatment of epilepsy afford a good example of the fact which has been previously pointed out that in some instances the vendors of secret preparations make use of drugs in common use by the medical profession for the treatment of some particular disorder; this is, of course, only possible when the symptoms are well-marked and easily recognised. As will be seen from the analyses given below of a number of nostrums advertised as remedies for epilepsy it was found that all, with one exception, contained bromide salts, that is to say, a drug the effect of which is described and discussed in every medical work dealing with the disease; nevertheless, the advertisers endeavour to lead the purchaser to believe that the preparations possess peculiar virtues unknown to the medical profession. The exceptional preparation contains vervain (_Verbena officinalis_) which held a place in the old pharmacopœias and herbals, chiefly as an astringent application to wounds or as a lotion for sore mouth. Dodoens (1572) says it is good for headache applied as a plaster, while Gerarde (1633) mentions its use as a garland round the head for the same condition, but he disapproves of the many old wives' tales told regarding it which tend to sorcery, and are such as honest ears abhor to hear; indeed, he hints that some assert that the "divell did reveal it as a secret and divine medicine." According to Pliny, vervain was gathered by the Druids of Gaul and Britain at the rising of the Dog Star, when neither sun nor moon shone, with the left hand only, and after libations of honey. When thus obtained it was said to vanquish fevers and other distempers, to be an antidote to the bite of serpents, and a charm to conciliate friendship. Paris speaks of it as in his own time the subject of a work on scrofula by a Mr. Morley, which was written for the sole purpose of restoring the much injured character and use of vervain, so that it is evidently a herb which has suffered much from detraction. Mr. Morley directed the root of the plant to be tied, with a yard of white satin ribbon, round the neck where it was to remain until the patient was cured. The modern vendor does not indulge in these refinements.

In submitting the following analyses it should be stated that a mixture or powder, dispensed according to the prescription obtained by the analysis, produced in each case a preparation closely resembling in appearance and taste that sold by the secret medicine vendor; further, the mixtures possessed the same specific gravity as the originals.

OZERINE.

"Ozerine," prepared by a chemist in Ireland, is described as an unfailing remedy for epilepsy, fits, or falling sickness. The bottle examined had no medicine stamp affixed.

The formula ascertained by analysis is as follows:

Potassium bromide 120 grains. Ammonium carbonate 16 " Burnt sugar q.s. to colour. Chloroform water to 1 fluid ounce.

Potassium bromide (111 grains) and potassium chloride (9■ grains) were found by analysis, but as some potassium bromide containing a large percentage of chloride had recently been in the market the latter was not regarded as an intentional addition.

Dose.—One teaspoonful before breakfast and dinner, and two at bedtime.

The price charged for a bottle containing 8 fluid ounces was 4s. 6d.; the estimated cost of contents was under 4d.

W. AND J. TAYLOR'S CELEBRATED ANTI-EPILEPTIC MEDICINE.

This preparation, sold in this country through an export agent in London, is said to be "simple, efficacious, harmless, and cheap." The effrontery of the following paragraph, extracted from a circular which was wrapped round the bottle, is amusing in view of the analytical results:

The principal drug is to be found in nearly every surgery, and yet not one doctor in a hundred would think of using it in Epilepsy, simply because he has no precedent to act upon—he is not directed by any of the great medical writers to prescribe or administer it in this disease; he knows not of its being so used, and he has not tried it himself, and thus he remains unaware of the one grand means of curing Epilepsy, even with the very drugs necessary at his elbow.

The formula ascertained by analysis was:

Tincture of iodine ¾ minim. Potassium bromide 13 grains. Ammonium bromide 4 " Water to 1 fluid ounce.

The mixture contained the proportion of iodine indicated in the above formula; but as it also contained traces of iodide, it was probable that tincture of iodine was used in its preparation. It may, however, have been prepared from an aqueous solution of iodine and potassium iodide.

Dose.—One teaspoonful three times a day.

The price of a bottle holding 12 fluid ounces was 2s. 9d.; the estimated cost of the contents is about 1d.

OSBORNE'S MIXTURE FOR EPILEPSY.

This mixture is stated to be prepared in a small town in England.

The following is an extract from a circular accompanying the bottle:

It scarcely ever fails to prevent the fits, loss of consciousness, convulsions, nervous twitchings, &c., of epilepsy, while at the same time it acts as a most valuable tonic; it allays irritation of the nervous system, purifies the blood, strengthens the frame, improves the general health, and helps to check the progress of disease on the intellectual faculties, and may be taken by the most delicate.

The formula ascertained by analysis was:

Potassium bromide 166 grains. Sugar 48 ” (= syrup ■j). Burnt sugar q.s. to colour. Peppermint water to 1 fluid ounce.

Traces of fixed ammonia were also present.

Dose.—One large teaspoonful morning and night.

The price charged for a bottle holding 5 fluid ounces was 2s. 9d.; the estimated cost of the contents is about 3d.

“PROFESSOR” O. PHELPS BROWN'S VERVAIN RESTORATIVE ASSIMILANT.

This preparation is recommended by the vendor—

“for the positive and speedy cure of epilepsy or fits, dyspepsia, indigestion, all derangements of the stomach and bowels, and for every form of debility, no matter from what source it may arise. An unequalled tonic and nervine.”

The formula ascertained by analysis was:

Decoction of Vervain (2 oz. to a pint) 4 fluid drachms. Port wine 1 ” ” Rectified spirit 2 ” ” Water to 1 fluid ounce.

The dose was stated to be one dessertspoonful three times a day before eating.

The mixture contained 25·75 per cent. of absolute alcohol by volume, and reacted towards lead acetate and lead sub-acetate exactly like a specimen prepared according to the above formula. It also contained the same amount of extractive, and had the same specific gravity.

The price is 2s. 9d. for a 6-oz. bottle. The estimated cost of the contents is about 5d.

TRENCH'S REMEDY FOR EPILEPSY AND FITS.

This is, or was, made by a company giving an address in Ireland. The package examined had no medicine stamp affixed.

Liquid Preparation.—The following formula refers to the liquid preparation supplied for use in the United Kingdom.

The formula ascertained by analysis was:

Potassium bromide 70 grains. Ammonium bromide 10 ” Sugar 72 ” (= syrup ■jss). Fuchsia q.s. to colour. Water to 1 fluid ounce.

The dose was stated to be one teaspoonful in the morning and two at night; the price for a 3-oz. bottle is 3s.; the estimated cost of the contents was about 1d.

“_Concentrated Form._”—This was supplied for export to the colonies, was a moist coarse brown crystalline powder in hermetically-sealed tins, with directions enclosed for dissolving in water. A quarter package (the smallest supplied) contained 11¼ ounces, and was directed to be dissolved in one pint of warm water. The resulting mixture was found to measure 25 fluid ounces.

From the formula given below it will be seen that the mixture thus prepared differed from the one issued for home consumption in two important particulars: (_a_) ammonium bromide was absent, (_b_) the dose of potassium bromide was considerably larger than that of the total bromides in the latter. Is this a form of colonial preference? or is it that our brothers beyond the sea are more robust and hence proof against the depressing influence of potassium salts? The formula of the powder ascertained by analysis was:

Potassium bromide 61 parts. Moist brown sugar 39 ”

The calculated composition of the finished mixture was:

Potassium bromide 120 grains. Moist brown sugar 77 ” Water to 1 fluid ounce.

The dose of the mixture directed to be taken was one teaspoonful in the morning and two at night.

The price charged for a quarter package was 15s., but the estimated cost of the contents is about 8d.

Such then are these secret remedies for epilepsy; with one exception they are weak preparations of well-known drugs supplied at considerably more than the usual cost, and administered without that careful adjustment of dose to the needs of the particular patient which is, after all, the most essential part in the treatment of epilepsy by bromide salts. The exception contains an old-fashioned herb once praised by the superstitious but abandoned time and again even by them; it has never been shown to possess any definite therapeutic properties and was long ago discarded by the medical profession because it was found useless.

SOME GERMAN NOSTRUMS.

Of five nostrums sold for the cure of epilepsy in Germany, examined by Dr. Zernik, three were found to contain bromide salts as chief constituents: _Lamma powder_ consisted of equal parts of bromide of sodium and bromide of ammonium; _Antiépileptique_ (Uten) was a solution of potassium bromide (16 per cent.), coloured green, and containing 1 per cent. of an indifferent bitter tincture, while _Berendorf’s powder for epilepsy_ contained potassium bromide 53·3 per cent., borax 40·3 per cent., and zinc oxide 4 per cent., the remainder being water. Borax is a remedy occasionally used to correct some undesired effect of bromides and has sometimes been prescribed for patients who could not tolerate the bromides. Zinc oxide has, or at one time had, a certain reputation as a nerve sedative. Of the two German remedies which did not contain bromide one consisted largely of formaldehyde which is used as an antiseptic and preservative for food, and the other consisted of pills containing nothing beyond inactive powdered leaves and roots.

CHAPTER XIV.

SOOTHING, TEETHING AND COOLING POWDERS FOR INFANTS.

The number of proprietary infants’ powders that can be said to be at all widely advertised is small, but some of them are sold in very large numbers. In addition, powders for the same purpose are very largely supplied by retailers, put up by themselves; they are usually of similar composition to one or other of those here described, but there is, of course, great scope for variations in the quantity and proportion, as well as in the nature of the drugs employed. It may, perhaps, be hoped that the efforts now being made by the employment of health visitors in many towns will, by the spread of instruction as to the common-sense management of infants, gradually lead to a great diminution in the custom so prevalent among the poorer classes of dosing infants whenever the curious foods, still so commonly given, cause indigestion.

STEDMAN’S TEETHING POWDERS.

The powders “with one e” are sold from an address in the north of London in boxes, price 1s. 1½., 2s. 9d., 4s. 6d., and 11s. The 4s. 6d. box contained 60 powders, and the 11s. box contained 216; the other sizes are stated to contain respectively 9 and 30 powders.

In a circular enclosed in the package it is stated that:

The returns of the Registrar-General tell us that the period of Dentition is one of more than ordinary peril to the child. It is a time of most active development, a time of passing from one mode of being to another, and we may fairly congratulate ourselves when this time of Teething be passed. To pass this time safely, and with the least risk to the child, one of “Stedman’s Teething Powders” should be given about twice a week, during the whole time of Dentition, according to the directions below....

When the bowels are moved regularly and the motions of a natural yellow colour, the Powders had better be omitted for a time, unless great irritability be present, accompanied with restlessness, then a dose had better be given. Diarrhœa will generally be checked by giving a dose at the commencement of the attack.

The directions are:

When the Child is under three months of age, the Third of a Powder only is to be given; from three to six months Half a Powder may be used; when above six months a Whole Powder may be taken.

The average weight of one powder was 2·4 grains; twelve powders weighed singly had weights varying from 2·25 to 2·6 grains. Analysis showed the powder to be composed of:

Calomel 29 per cent. Sugar of milk 71 ” ”

A trace of alkaloid was present also, and when extracted from the material of a large number of powders, was found to amount to only 0·016 per cent., or ¹/■■■■ grain in one powder. This trace of alkaloid did not show the behaviour of morphine, and did not give any reactions characteristic of any of the ordinary alkaloids, so far as it was possible to test for them on the minute amount available.

The estimated cost of the materials for the powders in a 4s. 6d. box is one-third of a penny.

STEEDMAN’S SOOTHING POWDERS.

The powders, “with two e’s,” are stated to be prepared in the south of London, and are sold in packets, price 1s. 1½d. and 2s. 9d. per packet; the 2s. 9d. packet contained twenty-four powders.

In a circular enclosed in the packet it is stated that:

The good effects of these Powders during the period of Teething have now had _Fifty Years’ Experience_, during which time _Thousands of children have been relieved annually_ from all those distressing symptoms which children suffer while cutting their teeth—viz., Feverish Heats, Fits, Convulsions, Sickness of Stomach and Debility, accompanied with Relaxation of the Bowels, and pale and green motions, or Inflammation of the Gums.

... the striking superiority both in the health and strength of those children who have taken the soothing Powders during the period of Teething has induced the Proprietor to make this MUCH-VALUED MEDICINE more generally known by this advertisement.

The directions are:

Dose.—From one to three months, the third of a Powder; from three to six months, half of a Powder; from six months and above that age, one Powder only and no more; ...

The average weight of one powder was 2·8 grains; twelve powders weighed singly had weights varying from 1·9 to 4·5 grains. Analysis showed the powder to consist of:

Calomel 27 per cent. Sugar 22 ” Maize starch 50·5 ” Ash 0·5 ”

A minute trace of alkaloid appeared to be present; the quantity was considerably less than in the Stedman’s powders described above, and so small, in fact, as hardly to give positive evidence of its alkaloidal nature.

The estimated cost of the ingredients of Steedman’s powders in a 2s. 9d. packet is one-eighth of a penny.

PRITCHARD’S TEETHING AND FEVER POWDERS.

The proprietors of these powders give an address in a large provincial city. The price charged is 1s. 1½d. for a box containing sixteen powders.

In a circular enclosed in the package it is stated:

The constantly increasing sale of these justly esteemed Powders proves them to be the most effectual Medicine that can be given to young children during the troublesome and anxious period of teething. By their gentle action on the Bowels, and valuable cooling

properties, they allay all irritation and Feverishness, prevent Fits, Convulsions, &c., ensure refreshing and natural sleep for the child, and therefore peaceful nights for the parents.

The directions are:

From one to three months, a third of a Powder; from three to six months, half a Powder; from six months and above that age, one Powder (not to be given if the child is relaxed).

The average weight of the powders was 2·1 grains; twelve powders weighed singly had weights varying from 1·9 to 2·3 grains. Analysis showed the powder to consist of:

Calomel 47 per cent. Antimony oxide 0·7 ” Calcium phosphate 1·4 ” Sugar of milk 50·9 ”

No trace of alkaloid was present.

The estimated cost of the ingredients of the powders in a 1s. 1½d. box is one-ninth of a penny.

FENNING’S CHILDREN’S COOLING POWDERS.

The proprietor gives an address in the south of England, and the prices charged are 1s. 1½d. and 2s. 9d. a box; the 2s. 9d. box contained 48 powders.

They were described in a circular enclosed with the box as:

The best medicine for infants cutting their teeth, preventing convulsions, thrush, disordered bowels, and for all the feverish diseases of infants and children.

The following directions are given:

For an Infant under _three_ years of age, give _one_ of Fenning’s Cooling Powders mixed with a little water, or it could be thrown dry as it is into the opened mouth of the baby, and gently holding back the head for half a minute it would be swallowed.

Whenever an Infant is restless or feverishly hot from Teething, when it is griped or sick from improper food, or over-feeding; has acidity, or a disordered stomach, _one_ of these Powders should be immediately given and, if necessary, repeated every day....

When a Child is attacked with Thrush, Measles, Hooping Cough, or Fever of any sort, always keep the feverish blood cool by giving a dose of _Fenning’s Cooling Powders_ every or every other day.

The powders had an average weight of 3·4 grains; twelve powders weighed singly had weights varying from 3·2 to 3·8 grains. Analysis showed the powder to consist of:

Potassium chlorate 70 per cent. Powdered liquorice 30 ”

The estimated cost of the ingredients of the powders in a 2s. 9d. box is one-sixth of a penny.

CHAPTER XV.

REMEDIES FOR EAR DISEASE AND DEAFNESS.

Some of the advertisements most frequently seen headed “Deafness cured,” “Eyes and Ears,” “Eye Diseases cured,” etc., do not refer to nostrums obtainable in the usual way through patent medicine dealers. The reader of the announcement is invited to write to the address given for particulars of special remedies, or an “interesting and convincing book post free,” dealing with the cure of diseases without operation, etc. Application for particulars brings much printed matter recommending the advertiser’s method, accompanied by a set of questions to be answered by the sufferer. If these answers are supplied and the fee demanded paid, medicine of some sort is sent. Medicines sold in this way, of which many other instances have been given in previous chapters, form a special class of “secret remedies,” and might be said, perhaps, to come rather under the head of prescribing at a distance, but it is, to say the least, very doubtful whether the composition of the medicines supplied is modified according to the answers given to the questions, and the two kinds of quackery are not sharply separated. In the case of the preparations now to be described, one or two belong more nearly to the class just referred to than to that of ordinary “patent medicines.”

We meet again the benevolent gentleman who having cured himself offers “to send particulars of remedy free,” but eventually sells his treatment at a price which would seem to represent no bad profit on the outlay for materials.

We also meet the dealer who to encourage the possible buyer sends a reduced price coupon only asking in return for the names and addresses of two or three friends who suffer in like manner.

ALFRED CROMPTON’S SPECIFIC FOR DEAFNESS.

This so-called specific, prepared in a town in the north of England, is sold in a bottle containing half a fluid ounce, and costing 1s. 1½d.

The label on the outside of the package was headed:

Deafness Cured!

and continues:

Alfred Crompton’s Specific for Deafness, Noises in the Ears, &c., is decidedly the best remedy out for this most annoying complaint. A single Bottle has in most instances effected a speedy and permanent cure.

The directions were:

Warm the Specific and Shake the Bottle. Two or three drops to be dropped in the Ear, night and morning, and rub behind and under the Ear with the Specific.

Analysis showed the following composition:

Soap 3·6 per cent. Glycerine 45·0 ” Oil 21·7 ” Water 29·5 ” Alcohol a trace. Oil of rosemary ”

There was a slight indication of a trace of camphor; probably this with the alcohol and oil of rosemary and part of the soap were added in the form of soap liniment. The oil gave analytical figures corresponding to a mixture of almond and colza oils in about equal proportions.

The estimated cost of ingredients, for ½-oz., is one farthing.

DELLAR’S ESSENCE FOR DEAFNESS.

This so-called essence, prepared it is stated by a company giving an address in London, and sold at the price of 1s. 1½d. for a bottle, containing two-fifths of a fluid ounce, is described on the label as “An old-established and valuable remedy.”

Directions for Use.—A small piece of wool, well moistened with the Essence, to be pushed into the cavity of the Ear every night at bedtime, and removed in the morning.

Analysis showed the composition to be;

Oil of turpentine 16 per cent. Fixed oil 84 ”

The properties of the fixed oil and the figures which it gave on further analysis corresponded to those of almond oil.

The estimated cost of the ingredients, for two-fifths of an ounce, is one halfpenny.

HERBERT CLIFTON’S TREATMENT FOR DEAFNESS.

This is brought to the notice of the public by an advertisement in the following terms:

A new cure for deafness. A Gentleman who cured himself after 14 years’ suffering will send particulars of remedy free.

Here followed the gentleman’s address, and an application brought a letter and a pamphlet entitled “Deafness and Noises in the Head, with Instructions how they may be Absolutely Cured,” which was marked “40th edition.” It professed to give an account of the writer’s own experiences. A few extracts will suffice to give an idea of it:

Those only who have suffered from the terrible calamity of deafness can understand the misery it brings into one's life; and only those who have had occasion to seek the assistance of men who profess to cure this awful affliction can appreciate how utterly its treatment is misunderstood by the various advertising empirics who profess to cure it, whether by electrical, galvanic, or any of the other methods which are so alluringly set forth as perfectly infallible by people who never suffered themselves, who can have no sympathy, therefore, with those whom they profess to assist, and whose only object is to extract as large a sum as they possibly can from the pockets of those whom they have been able to attract to their spider's parlour. The writer, however, of the present pamphlet is in a different position.... As a lad I began to suffer from noises in the head, which as time went on increased to such an alarming degree that I was taken to an Aural Surgeon.... The usual result followed. I became worse and worse, and, of course, weaker through his treatment.... Another doctor was consulted.... But the treatment failed, my affliction increased, and MY LIFE BECAME A BURDEN.... There seemed no hope for me. Nearly a dozen eminent surgeons had seen me, examined me, said different things about me, and indifferently treated me; but all to no purpose.... As a last resource I tried the various quack remedies which have allured so many to their bitter cost, and many a pound was wasted on mechanical, electrical, magnetic, and other useless appliances, and upon ear-trumpets, drums, tubes, &c., with no result.... Then the wild, yet happy, thought flashed across me: "Why not try and cure yourself?" I pondered and pondered over the idea, and at last, rather than submit to my fate, determined to study physiology and medicine and endeavour to discover the cause of my deafness, with the distant hope that I might alight upon the method of its cure.... The conclusion I came to was that what I really required was a medicine which should reach the minute muscles of the inner ear, as upon their proper action the sense of hearing almost entirely depends ... after a time I had succeeded in discovering a preparation which would do the required work.... My disease was of so long standing, that I had found it had caused the drums of my ears to become weak and shrunken ... and I soon devised a small appliance to fit inside each ear—the appliance which I now term the "Invisible Drum Support" ... in my gratitude to the Almighty for my merciful deliverance I vowed that I would publish to the world the method by which I had struggled out of the dark past into the brilliant light of the present.

A postscript to the letter stated that "No charge whatever is made for advice, so you need not hesitate to avail yourself of the benefit of my _opinion_," but no information was vouchsafed as to the price charged for the "treatment," except that it would be found extremely moderate. Paragraphs, of the usual inspired kind, were quoted from the _Family Doctor_, _Christian Union_, _Family Churchman_, _Health_, and local newspapers of varying degrees of obscurity.

The letter and pamphlet were followed after an interval by another letter, as follows:

Dear Friend,

Referring to your application for my Pamphlet some time back, I shall be glad to know whether you wish me to proceed further in the matter. As I have received no letter from you, I presume that you imagine the cost of treatment will be too high. I will, therefore, make you a Special Offer, that is, for the sum of 10s. (which may be paid in two monthly instalments of 5s. each, if more convenient) I will forward you the full Treatment and Directions. Should you avail yourself of this offer, kindly detach the form at the bottom of this letter and return to me. The Treatment is, without doubt, the most effectual ever placed before the Public, as will be found by the numerous testimonials received.

I am daily in receipt of letters similar to those enclosed herewith, and I feel confident that, should you give the treatment a trial, you will also be able to report quite as good results.

Kindly let me know your decision as soon as possible. If you will take my advice you will not further delay.

May I draw your attention to the letters on the other side?

I am, yours faithfully, HERBERT CLIFTON.

The "treatment form" was filled up and sent in with 10s., and, as was to be expected, "my candid opinion as to whether my system of treatment is calculated to efficiently meet the requirement," was apparently in favour of treating the case, as a pair of "drum-supports" and a bottle of fluid were received, together with a letter asking the recipient to follow out the directions given very carefully and not be disheartened "because you find no improvement immediately, you must give the Cure a fair trial. I shall be glad," the letter concluded, "to hear from you in about three weeks' time with a general report on your case."

The "drum-supports" consisted of half-inch lengths of narrow india-rubber tubing, as used for the valves of bicycle tyres, with an inner tube of "gum-elastic," the india-rubber being expanded at one end into a funnel ¼ in. long, and attached at the other to a small oval disc of sheet india-rubber. The prime cost of the pair would probably not exceed 3d. The bottle was labelled "No. 1. Price 3s.,"

and contained 1 fluid ounce of liquid; analysis showed this to have the following composition:

Glycerine 10 per cent. approx. Oil 28 ” ” Ether 2 ” ” Water to 100

A trace (about 0·01 per cent.) of an alkaline substance was present, which appeared to be borax. The oil showed the characters of almond oil.

The estimated cost of the ingredients, for 1 oz., is one halfpenny.

OHRSORB COMPOUND.

The following advertisement is taken from _Cassell’s Saturday Journal_:

DOCTOR MAKES DEAF HEAR.

A medical book just published describes a German doctor’s wonderfully simple cure for deafness and head noises (a real home cure). A limited number of those books have been secured for readers of _Cassell’s Saturday Journal_, and will be sent free by post by the publisher, M. Franckel.

Application to the London address given brought a pamphlet of sixteen pages, from which a few extracts are here given:

For years it has been known to Medical Men that the minute vessels or channels of the lymphatic system underlying the skin, covering the bone behind the ear, were intimately connected with those supplying vital nourishment to the middle and internal ear, where we find the common seat of deafness and head noises. If, then, we could medicate through the skin, this important current of lymphatic fluid, controlling the health of the essential parts of the organ of hearing, our medications could be made to flow inward to reach and to cure a disease so deeply hidden within the ear as to be otherwise regarded as incurable. It is the province of this little work to explain why the prescriptions of so many aurists have failed in years past, and to present a new chemical compound which is of the utmost value to deaf people.

Applications behind the ear are recommended in the writings of our greatest ear surgeons. Gruber, Politzer, Delstanche, Grünfeld, and numerous others have given us prescriptions of this kind, and, although their combinations of drugs have failed to produce any remarkable results, they have pointed out the remedies that would cure if combined with a substance which could penetrate the skin freely.... Until lately we possessed no basis for our ointments, embrocations, or plasters, which could freely penetrate the skin.... Happily there is a new basis lately brought to the notice of the medical profession, which has the remarkable property of uniting with the watery secretions of the body in such a way that it (_sic_) absorbed by the skin, and taken up by the lymphatic circulation (described on p. 1), together with any drugs that are combined with it in the form of an ointment.... To this new basis has been given the name “Ohrsorb.”

Quotations purporting to be from the writings of medical men are given, but no references are provided by which they can be checked; and, indeed, the extracts only refer to a “new preparation” and a “new treatment,” without any indication that the advertised article is the one intended. Another quotation is then given “From the Private Clinical Memoranda of Dr. Kupfinn,” described as an “Hon. Auris Chirurgis,” in which “Ohrsorb” is referred to in a laudatory manner; this is followed by an account of some “typical cases,” but it does not appear that this is part of the quotation, although it is so put that it might easily be taken to be. The pamphlet continues:

It should be clearly understood that Ohrsorb by itself is only a basis used solely for the purpose of providing the _active portion_ of the Author’s Absorption Treatment, and that the cure depends on the medicinal action of the drugs compounded with it in any special prescription. It is for this reason that certain particulars as to each patient’s case are asked for on the enclosed coupon, namely, that the individual form of deafness, head noises, or ear trouble may be treated by an “Ohrsorb” compound specially adapted to it.

The pamphlet proceeds to give reasons for supplementing the treatment by the use of other articles, of which the following are recommended: “Ohraseptic,” “Nazaseptic,” “Specially Prepared Catarrh Tonic,” a nasal irrigator, and a safety ear syringe. It was accompanied by a leaflet headed, “Medical Report on the ‘Ohrsorb’ Treatment,” in which many testimonials are given, but not one from a medical source or anything of the nature of a medical report; also by a “reduced price coupon,” offering a 2s. 9d. tube for 1s. 6d. or a 4s. 6d. tube for 3s., provided the applicant undertook to use it as directed and report the result, and a list of about fifty questions to be answered in connexion with deafness, &c., and catarrh of the nose and throat, concluding with the following

paragraph:

As a little return for supplying the tube of “Ohrsorb” compound at the reduced price, and for the very special attention that will be given to your case, the author will be grateful if you favour him with the names and addresses of two or three of your friends who suffer from deafness, head noises, or catarrh of the nose or throat. This is entirely confidential, and your name will not be mentioned.

In order to test the importance attached to the answers to the questions, a supply of “Ohrsorb Compound for Deafness” was sent for, without giving any particulars of the supposed case for which it was required. The compound was at once sent, together with a multiple-typed letter of the usual kind, as shown by the following extracts:

“I hope you will not neglect to write me about your progress with my treatment”; “of course you will appreciate that in obstinate cases Ohrsorb must be persisted with for some time before the improvement can begin to show itself.”

and offering for future supplies three 4s. 6d. tubes for 10s. 6d.

The “Special Ohrsorb Compound” is supplied in collapsible tubes, and the 2s. 9d. size contained just over ½ oz. of ointment. The directions were to rub the ointment once, twice, or thrice a day over the skin close behind the ear, and also from just beneath the ear around to the front of the throat, for three to five minutes.

The ointment, nearly black in colour, contained about 70 per cent. of vaseline, and about 4 per cent. of beeswax, a little soap, and a little saponifiable fat; sulphur and ammonia were present in combination, and the dark constituent appeared to be of the class represented by thiol, tumenol, and petrosulfol, artificial compounds intended to take the place of ichthyol, and like it containing much sulphur in combination but free from its disagreeable odour. The total sulphur found in “Ohrsorb Compound” was 0·8 per cent., which corresponds to about 8 per cent. of one of these substances. An ointment made up with tumenol, soft paraffin, wax, and a little ammonia soap resembled “Ohrsorb Compound” very closely, though the correspondence was not quite complete. It was not considered worth while to isolate the dark constituent in a state of purity permitting of more precise identification than is here indicated; to determine the detailed characterization of such a substance a large quantity would be necessary.

CHAPTER XVI.

REMEDIES FOR EYE DISEASES.

The proprietary articles advertised for the cure of diseases of the eyes, though perhaps not so numerous as some other classes of nostrums, vary a good deal in nature, but the claims made for most of them are equally comprehensive. The results of analysis of a few are here given and it will be seen that two of them, including one called “botanic,” are mercurial ointments. Another advertiser seems to think or pretends to think that cataract can be cured by bathing the eyes with soda alum dissolved in coloured water, while we come across also an “Ophthalmic Institution” selling for external application an anti-cataract mixture consisting of glycerine with a little potassium iodide and starch.

SINGLETON’S EYE OINTMENT.

This is stated to be prepared, by a person whose name is not Singleton, at an address in London. The price charged is 2s. for a pot containing about 55 grains.

The ointment is described on the outer package as

“An Absolute Specific for all Eye Troubles and Diseases.”

On a circular enclosed in the package it was stated:

“It cures Weak Sight, Inflamed Eyes, and all disorders of the Eyelids from whatever cause arising.... Singleton’s Eye Ointment requires great skill in making, and is composed of costly ingredients. One pot will cure you.... The Ointment also cures Piles and Scorbutic Eruptions.”

A book dealing with the ointment was also supplied, in which it is stated that

“Singleton’s Eye Ointment will cure all affections of the eye.”

Analysis showed the principal ingredient to be red mercuric oxide, of which 7·4 per cent. was present. The fatty basis contained about 4 per cent. of beeswax, and the remainder was a practically neutral and colourless substance which agreed in properties and analytical figures with a mixture of lard, Japan wax, and purified cocoanut oil. It is, of course, impossible to determine with certainty the composition of a mixture of fats, unless a large quantity is available for analysis; but the exact nature of the fatty basis is immaterial, and no indication was obtained of any other medicinal ingredient.

The assertion that such an ointment "requires great skill in making" is absurd, and as to the costliness of the ingredients, the 55 grains in the pot are estimated to be worth one-ninth of a penny.

BOSTOCK'S EYE OINTMENT.

This ointment, stated to be manufactured by a limited company with an address in London, is sold in a pot containing half an ounce, and costing 1s. 1½d. It is described on the label as "An invaluable remedy for every Disease to which the Eye is subject." In a circular wrapped round the pot it is called "Bostock's Botanic Eye Ointment," which

is strongly recommended as a valuable Restorative and Preserver of the Sight, removing Inflammation, Bloodshots, Scorbutic Humours, Shooting Pains, Dimness, Swelling in the Eyelids, and numerous other diseases to which the Eye is subject; it also preserves the Sight against the injuries arising from extreme Heat and Cold.

Analysis showed the presence of small quantities of ammoniated mercury (commonly known as white precipitate) and an insoluble compound of lead which appeared to be the oxide; a little glycerine was present, and a bitter, light-coloured substance of the nature of an extract; this contained no alkaloid, and gave no characteristic reactions indicating the drug or plant from which it was derived; a trace of a vegetable powder was also found, the quantity being so very small that it was probably only an accidental contamination of the extract; when examined microscopically it appeared to consist chiefly of the tissue of a seed. The basis of the ointment contained soft paraffin and spermaceti, and a third constituent agreeing in its characters with lard. Determination of the amounts of the respective ingredients indicated the following approximate formula:

Ammoniated mercury 0·88 per cent. Lead oxide (litharge) 0·15 " Glycerine 2·25 " Extractive 3·32 " Spermaceti 31·0 " Soft paraffin 31·0 " Lard 31·4 "

Neglecting the extractive, the estimated cost of the ingredients for half an ounce is under one halfpenny.

A NEW AND MARVELLOUS REMEDY FOR THE EYES.

This substance, sold from an address in Wisbech at the price of 2s. 9d. for a packet containing 135 grains, was enclosed in a small envelope, on which was written, "Remedy for Eyes only"; there was no printed label except the revenue stamp. In the accompanying circular it was described in the following terms:

A Cure for Cataracts, Films, White Specks, &c. without Operation. The Remedy Cures and Improves the Sight when every other remedy and human skill fails. The Remedy within Twelve Months has proved itself to have no equal for removing Cataracts, Films, White Specks, &c., and is guaranteed the greatest and most marvellous Remedy in the world for such, and for all Eye Sufferers.

Directions for use were given in another circular, as follows, and seem worth quoting as an illustration of pretensions so preposterous that they seem calculated to defeat their own object even when addressed to the most credulous:

Divide the packet of powder into four parts; into an ordinary six ounce medicine bottle put one part out of the four, then fill up the bottle with pure water. Filter or strain the water before so doing, then let the Lotion stand all night after it is made, it is then ready for use. Keep the remainder of the powder in a dry place until required for use.

Shake up the bottle well before using, and in case of Blindness or very bad eyesight, for deep-seated Inflammation, Cataracts, White Specks, &c., pour some of the Lotion into an earthen cup or basin, and bathe the eyes three times a day, about two minutes at a time, and let the Lotion go well into the eyes by winking them whilst bathing them—the Lotion will do no harm by going well into them, for good results can only be obtained in such cases by the remedy going well into the eyes. After bathing the eyes cover up the Lotion with a saucer or plate to keep dust, etc., out, until required for use again. Use a piece of linen rag for bathing the eyes.

N.B.—For Painful, Bloodshot, Weak, Dim, and Misty Eyes, or Floating Black Specks, or for Eye Strain, Etc., and for Strengthening the Optic Nerve, Etc., and for Inflammation, Short Sight, Etc.—Simply bathe the eyes twice a day, morning and night, just before

going to bed, about two minutes at a time, letting a little of the Lotion go into the eyes, and should the Remedy make the eyes smart too much, and too long, or make the eyes inflamed or water, etc., too much, make the Remedy a little weaker by adding a little more water to same quantity of Powder, or by not putting quite so much powder to same quantity of water.

This circular concludes with the following notice:

Please Note the Remedy can only be had direct from the Proprietor himself, as no other human being in existence sells it.

The package was accompanied by a written paper as follows:

Please note. Since instructions have been printed I find it necessary for a slight alteration for the benefit of those suffering from Cataracts, Films, and white specks. In such cases when first commencing to use the remedy divide the packet of powder into 4 parts make one bottle out of one part and use according to instructions. After the use of first bottle divide the rest of the powder into 2 parts you will then have sufficient for 2 bottles and will therefore have remedy much stronger of which is needed in case of Cataracts, etc. And when more remedy is required always divide the packet into 3 parts sufficient to make 3 bottles and follow instructions.

(P.S.) I may say for the benefit of those suffering from Cataracts, Films, and white specks the best and quickest results have been obtained by using one bottle per week.

The packet contained a coarse pink powder, with many white particles. Analysis showed it to contain:

Basic aluminium sulphate 48·2 per cent. Sodium sulphate (anhydrous) 18·3 ” Colouring matter a trace.

the remainder being water. The double sulphate of aluminium and sodium, or soda alum, contains 48·8 per cent. of aluminium sulphate and 20·3 per cent. of sodium sulphate, and the substance under examination thus practically consisted of this salt, somewhat deficient in sulphuric acid. The colouring matter did not quite agree in its behaviour with any of the common pink colours, though it was very similar to acid magenta.

The estimated cost of 135 grains is one-twentieth of a penny.

POMIES’ ANTI-CATARACT MIXTURE.

This application is sold from a place called an Ophthalmic Institution in London at the price of 2s. 6d. for a pot containing 162 grains.

It is one of a series of preparations sold under the name “Pomies,” including anti-cataract oil, anti-inflammation eye lotions Nos. 1 and 2, sedative collyrium, and others. The package itself was singularly free from printed matter; the directions on the label were as follows:

“Take some of the Mixture on a camelhair brush and introduce it into the eye in wiping the brush between the lids two or three times, twice a day.”

Analysis showed the composition of the substance to be:

Potassium iodide 5·6 per cent. Glycerine 56·5 ” Starch 6·4 ” Water 31·5 ”

The estimated cost of the ingredients, for 162 grains, is one-third of a penny.

SOME GERMAN NOSTRUMS.

The eye preparations analysed by Dr. Zernik are not very interesting. One called _Okterin_ is a sulphate water, colourless, odourless, acid, and astringent, apparently pumped out of a mine containing ochre. Another sold under the name _Opthalmol_, and described as a natural remedy for all kinds of eye disease is supposed to be made from the glands of a fish. It yielded analytical data which appeared to prove that it was rancid olive oil, with 6 or 7 per cent. of a mineral oil like paraffin. A third wonder-working application, _Augenwol_, said to be made from various plants obtained from many countries proved to be a coloured and perfumed solution of common salt containing a little glycerine and some extractive substances.

CHAPTER XVII.

REMEDIES FOR PILES.

The series of analyses of secret remedies for hæmorrhoids, and the extracts from the advertisements by which these nostrums are commended to the public, make it evident that the prevalence of this complaint, which is always disagreeable and painful, and sometimes incapacitating, provides a happy hunting ground for the nostrum monger. An additional attraction is, perhaps, to be found in the fact that considerable variety is possible in the method of treatment. Local applications, represented by suppositories and ointments, appear to be most in favour, but there is an obvious opportunity for the man who wishes to sell a medicine to be taken internally to declare that local applications "only afford temporary ease, and do not tend to remove the cause. Only internal treatment can cure." The further possibility of extracting double or threefold payments from sufferers by insisting on the necessity of both local and internal remedies has by no means been neglected; in some cases one preparation only is advertised, and after obtaining this the sufferer learns that something further must be bought if the promised cure is to be effected. In another case, where the remedy is a "threefold treatment, because there are three avenues of approach to the seat of the ailment," it is advertised to be sent without payment, the money to be paid after a week's trial if benefit has been received; any one availing himself of this offer necessarily supplies the vendors with his name and address, and will then, it seems, become the recipient of numerous letters, emphasizing the dangers of neglect, and offering "our full-size guinea treatment" on special terms. It has been shown in previous chapters that this method of doing business directly with the persons taking quack remedies is in great, and apparently growing, favour with makers of such things. The letters with which the sufferer is inundated are, as a rule at any rate, printed in imitation of typewritten letters or reproduced by some manifolding process, and the recipient, unless he be something of an expert, is likely to suppose that he is receiving letters composed for his personal benefit, an illusion that is sedulously maintained by a profession of "special interest in your case," or some equivalent fiction. The majority of the preparations described in this chapter contain substances commonly employed for the relief of piles, such as hamamelis (witch hazel), lead acetate, zinc oxide, calomel, or others, if possible, still more old-fashioned; some, like the "Muco-Food Cones, containing concentrated glutinous nourishment," consist of flour and cocoa butter, and are innocent of medicinal ingredients. Advertisers, of course, indulge in the usual impudent reflexions on the work of the medical profession; one, for instance, hazards the statement that "for centuries piles have been treated in a careless, listless, manner by physicians, who, through ignorance or indifference, were unfit to be entrusted with such cases." These same advertisers remark: "The people do not like to be humbugged"—a statement, perhaps, as far from the truth as some other assertions in the advertisements and letters. One company—two of whose "cures" have been shown in previous chapters to consist of sugar only, and whose ointment for piles is about equally active—invites those who are not cured by it to detail their symptoms to "our medical correspondence department"; it is easy to believe that "you will receive the same thorough attention from our medical staff as if you were examined personally," but how much attention that would be is wisely not stated. The majority of the articles are of American origin, some of them being marked "Made in U.S.A.," and others being now prepared in this country, but having originally come from across the Atlantic. Whether English or foreign, however, the usual disproportion is to be found between the prime cost and the price charged. If in the present series the highest price is charged—and the greatest pertinacity in extracting the sufferer's money is shown—by a transatlantic concern, in other chapters English quacks have been shown well to the fore as regards both price and methods.

BUER'S PILES CURE.

On purchasing from an address in one of the Home Counties Buer's "Piles Cure" for 1s. 1½d., it proved to consist of a box of Buer's Mul'la, and a single sample powder of Buer's Pile Powders, which cost a further 1s. 1½d. for a box. Several circulars were enclosed in the package. The trade mark was a picture of a donkey; a few extracts will suffice as specimens of the statements made:

Is it money (1s. 1½d.) or your life? Buer, the founder, the proprietor is the seventh son, not trading on his birthright but on his cure, testified by hundreds. Warrants it will cure you. If you suffer, will you try it?

The pains experienced range all the way from the slightest itch to the most terrible sufferings, which appear like tearing the body asunder, and unless the piles are cured with Buer's Mul'la there is no relief....

They cause you to be despondent, caring little to live; no go in you; quarrelsome in yourself; weakening to the constitution; until something gives way and hastens your death. It is therefore money or your life; no hesitation.

But one thing—not for the sake of selling the Powders—keep a box of Buer's Pile Powders in house—12 for 1s. 1½d. ain't dear—and take one as directed whenever you feel any irritation.

The box of ointment contained two-fifths of an ounce. The directions were:

Apply this Mul'la to parts affected.

Analysis showed the ointment to contain:

Lanoline (anhydrous) 66·5 per cent. Beeswax 1·5 " Water 32·0 "

Hamamelis ointment is usually made from the liquid extract which contains rectified spirit, but no alcohol was present in this oddly-named preparation; it may have been made with liquor hamamelidis prepared without the use of alcohol; a minute trace of water-soluble substance contained in the ointment suggested by its behaviour with reagents that such was the case. The estimated cost of ingredients is three farthings.

Twelve of the powders are supplied in the 1s. 1½d. box. The directions are:

To be taken at bedtime in a glass of milk or water.

Analysis showed the composition to be:

Precipitated sulphur 14·9 grains. Calcined magnesia (partly carbonated) 23·6 "

in one powder of average weight. Single powders in one box varied from 28 to 48 grains. The estimated cost of the ingredients for twelve powders is 1¼d.

MUNYON'S PILE OINTMENT.

This ointment is supplied by the same Homœopathic Home Remedy Company as has been encountered in earlier chapters. The price charged was 1s. a package, containing a collapsible tube holding 1 oz. of ointment and a metal tube for introducing it.

On the outside of the package it was stated that the ointment

permanently cures all forms of Piles or Hemorrhoids, and immediately relieves pain, burning, itching, and distress at the outlet of the bowels.

In the circular enclosed in the package, in which thirty of this company's preparations for different complaints were advertised, it was stated that the ointment

cures piles, blind or bleeding, protruding or internal, stops itching instantly, allays inflammation, and gives ease at once to the sore parts, heals fissures, ulcerations, cracks, and all anal troubles."

A label on the tube of ointment asked the purchaser

if this remedy fails to cure him, to write to the proprietor stating fully all your symptoms. He will have your case carefully diagnosed, and, you will receive the same thorough attention from our medical staff as if you were examined personally. All communications are kept strictly confidential, and replies are sent in plain envelopes. Our Medical Correspondence Department is having great success in curing old obstinate cases. Remember we sweep away all fees for medical advice, we put special medical attention at your service absolutely free. We want you to feel at liberty to write us whenever you need any medical advice, and to fully understand that there will be no charge of any kind for our service.

Analysis showed the ointment, which was directed to be applied three times a day, to consist of soft paraffin, with a trace of ichthyol sufficient to give a slight odour, but not enough to affect the appearance of the ointment. Experiments showed that 0·2 per cent. or over of ichthyol appreciably darkens the colour of soft paraffin, and it appears therefore that less than this proportion was present. The estimated cost of one ounce of the ointment is one farthing.

DOAN'S OINTMENT.

This is sold by a company giving an address in London; the price is 2s. 9d. a tin, containing 1■ oz.

On the package it was stated that

Doan's Ointment cures Piles, Salt Rheum, Chilblains, Eczema. Cures Black-headed Pimples, Hives and any itching disease.

In the enclosed circular it was referred to as:

The “Thorough” Cure for Piles, Eczema, Shingles, and Itching Diseases of the Skin.

And the statement was made that:

Bleeding and torturing itching piles are quickly and thoroughly cured by Doan’s Ointment, relief being usually obtained from the first application. A cure will follow—a “thorough” cure.

A “Pile Pipe” was supplied at 6d. for applying the ointment to internal piles; for external piles it was directed to be applied with the finger or a piece of clean soft rag. Analysis showed the composition of the ointment to be:

Calomel 36·0 per cent. Zinc oxide 11·2 ” Phenol 1·3 ” Beeswax 2·3 ” Soft paraffin 49·2 ”

The estimated cost of the ingredients is 2d.

OXIEN MEDI-CONE PILE TREATMENT.

The sole proprietors of this treatment are stated to be “The Giant Oxie Co.,” of a town in the U.S.A., but having a British depôt in London. The price charged for a box was 2s. 3d.; it contained twelve suppositories, described on the label as:

Warranted to cure Blind, Bleeding, or Itching Hemorrhoids, and all other Diseases of the Lower Bowel and Rectum.

The following extracts are quoted from the enclosed circulars:

Just so far as an electric light is ahead of a tallow candle, is the Oxien Medi-Cone Pile Treatment in advance of and superior to all other remedies for Rectal Diseases.

The people do not like to be humbugged. Modern Men and Women demand modern methods of treatment. With this in view we have after careful painstaking study and experimenting organized a radically new method for the positive cure of Bleeding or Itching Piles or Hemorrhoids, Rectal Ulcers, Fissure, Polypi, Fistula, and all ailments of the Rectum and Lower Bowel....

If you are a sufferer from this terrible malady which has scourged people of all classes of society, in every clime since Bible times, do not now give up. You can be cured. For centuries Piles have been treated in a careless, listless manner, by physicians who through ignorance or indifference were unfit to be entrusted with such cases, or by quacks who by questionable methods and high-titled nostrums extracted dollar after dollar from patient sufferers. During the past few years, however, a great awakening has taken place. The people demanded a suitable and satisfactory treatment and students have been at work, and the subject and its cures have had the most careful and scientific attention.

The result of the careful and scientific attention of the students is these suppositories, which were found on analysis to have the following composition:

Lead acetate 5·6 per cent. Creasote, about 2·0 ” A resinoid substance 3·0 ” Vegetable tissue 1·0 ” Hard paraffin 7·0 ” Oil of theobroma (cocoa butter) 81·4 ”

The resinoid substance showed the presence of tannin; it could not be identified with any certainty, but may have been “hamamelin,” an extract of hamamelis (witch hazel) for which there is no official standard or method of preparation, but it did not agree closely in character with the hamamelin ordinarily supplied in this country. The vegetable tissue appeared to be that of a young leaf, and from the peculiar nature of the hairs was probably hamamelis leaf; the mature leaves as imported into Great Britain, however, possess characters which were absent. The suppositories were of the average weight of 19 grains, and the estimated prime cost of the ingredients for twelve is 1¼d.

HEMOTORA.

The fluid to which this name is given is stated to be manufactured for a company by a chemist in Cheshire. A bottle containing nearly 4 fluid ounces, costs 2s. In the accompanying circular the company’s views as to the cause of piles are expounded as follows:

Hemotora is a Concentrated Extract of Herbs which has been tested and proved beyond doubt to be a “Certain Specific for Piles.” A short explanation will clearly show the action of Hemotora. Should any hindrance occur to the flow of blood through the hæmorrhoidal veins, they naturally become congested and distended; this further brings about a thickening of the vein walls, eventually developing painful tumours called “Piles,” or technically, “Hæmorrhoids.” The many and various conditions that eventually produce Piles can always be traced to this accumulation of blood, and it is in this direction, the very basis of the complaint, that the active principles of Hemotora display their wonderful efficiency by removing the obstruction to the natural flow of blood; the parts will then return to their original condition and functions. Relief may be obtained from the external use of Ointments, Creams and Suppositories, but these preparations only afford temporary ease, and do not tend to remove the Cause. Only internal treatment can cure. Results show that External, Internal, and Bleeding Piles alike soon yield to this remedy; after a few doses the pain is greatly alleviated, accompanied by a sense of relief from the sickly feeling of lassitude and depression. The tonic properties of Hemotora quickly restore the general health.

From another circular it appears that

The “Hemotora Salve” for Itching Piles is sold in small 1s. Jars, large size, 2s. 6d.

Analysis of “Hemotora” showed it to be an aqueous liquid containing about O·09 per cent. of a bitter amorphous alkaloid and 2·7 per cent. of vegetable extractive, including a little of a substance of the nature of a tannin, but not medicinal tannic acid. The liquid appeared to be produced by aqueous extraction, infusion or decoction, of some bitter vegetable substance.

ROLLO’S REMEDY FOR PILES.

This ointment, made by a Scottish company, is sold in tins, price 1s. 1½d., containing rather under 1 oz. It is described in an accompanying circular as a remedy for a good many disorders besides Piles:

Rollo’s Remedy for Piles, Eczema, Rheumatic Pains, Burns and Scalds, Chilblains, Soreness or Roughness of the Skin, Itching.

Rollo’s Remedy is a Vegetable Extract in the Highest Possible State of Purity, without any addition whatever. It is obtained from a little known part of Africa, and has been brought to its present perfection after a long series of scientific experiments. It does not contain any Poisons, Drugs, Chemicals, or Impurities of any kind, and although intended for external use only, it is so pure that even if eaten it would be quite harmless.

Analysis showed the ointment to contain over 99 per cent. of fatty basis, with a very small quantity of a dark substance which appeared to be vegetable extractive. It contained no alkaloid and no tannin, and possessed no characters indicative of the drug or plant from which it was derived. The basis showed the characters of a mixture of fats in which oil of theobroma (cocoa butter) predominated, with about 15 per cent. of lanoline (anhydrous).

DR. VAN VLECK’S COMPLETE ABSORPTIVE PILE TREATMENT.

The preparations sold under this name are, or were, very widely advertised by a company giving an address in London. They are offered without previous payment, as indicated by the following extracts from an advertisement:

To every person who sends us the coupon below at once, we will send—Free to try—our complete new threefold absorption cure for Piles, Ulcer, Fissure, Prolapse, Tumours, Constipation, and all rectal troubles. If you are fully satisfied with the benefits received, send us 4s. 6d. If not, we take your word, and it costs you nothing; you decide after a thorough trial.

Our valuable new Pile Book (in colours) comes free with the approval treatment all in plain package. Send no money—just the coupon—to Dr. Van Vleck Co.

The “new Pile Book,” a pamphlet of 40 pages, entitled “The Rational Treatment of Rectal Diseases,” included a description of the rectum, with eleven illustrations—several of them coloured—with descriptions of various kinds of piles and treatments, and of the Van Vleck remedies. A few extracts only can be given:

Unless you are beyond every chance of recovery, this wonderful threefold Absorption treatment will cure you....

The Absorption Cure is Threefold because there are three avenues of approach to the seat of the ailment. To neglect one of these avenues means to leave an open gateway for the return of the malady. Dr. Van Vleck struck at the well spring of the disease, as well as at the visible effect of it. Once cured by our treatment the disease is cured to stay cured. There is no pain, no confinement,

no heavy doctor's or surgeon's bill, no operation. The cost is placed within the reach of all, and the treatment is accompanied by a positive guarantee of cure. The treatment embraces:

1. Dr. Van Vleck's Absorptive Plasma. 2. Dr. Van Vleck's Muco-food Cones. 3. Dr. Van Vleck's Pile Pills (and System Regulator).

The "positive guarantee" is given inside the back cover of the pamphlet, as follows:

GUARANTEE.

The Dr. Van Vleck Co.... Hereby positively agrees that Dr. Van Vleck's Absorption Cure for Piles, when taken and used in accordance with our simple instructions and directions, will cure any case of Piles, and in the event of its failure to cure,

AGREES TO REFUND

The entire amount paid immediately upon required statement that benefit has not been received.

The Dr. Van Vleck Co.

It will be observed that this purported to be a guarantee to cure, and would be read by most as a promise to refund the amount paid if the treatment did not cure; whereas it was only a promise to refund if a "required" statement were made that benefit (that is, any benefit) had not been received, a statement most uncured persons might hesitate to make.

On application for the 4s. 6d. treatment, 5 suppositories, 10 pills, and about 65 grains of "plasma" in a collapsible tube were sent, with a long circular letter of the usual type, offering the:

Large special treatment, including our new Rectal Applicator, made from pure Stannum,[2] for 21s., or for 16s. 6d. in addition to the 4s. 6d. to be sent for what was supplied.

[2] _Stannum_: tin. _Latin Dictionary._

The labels of the preparations were stamped "made in U.S.A."

Letters subsequently received urging continued use of the treatment and pressing for particulars of the case, were much like those from other nostrum dealers which have been printed in earlier chapters, and included such statements as:

We have made a special study of your case, and we are convinced that if this, our final offer to _you_, is accepted, a permanent cure will be assured.

No "case" had been even mentioned in sending for the preparations. The "final offer" was:

On receipt of 12s. 6d. we will forward you our Full Size Guinea Treatment, post free. We are perfectly willing to trust to you to remit us the balance of 4s. on completion of the cure. Remember you are absolutely protected by our guarantee (see last page of booklet).

Other papers sent were a "Patient's Special Symptom Form," to be filled up after using the "treatment," and including such questions as "Are your Piles better?" "Please state in what way your condition has changed since you commenced taking our treatment," and a form for names and addresses of other persons suffering from piles.

Analysis of the "plasma" showed it to be a paraffin ointment containing about 6 per cent. of powdered galls and a small quantity of menthol (approximately 1 per cent.); the basis consisted principally of soft paraffin, with a dark substance which appeared to be the natural impurities of crude petroleum. The formula is thus approximately:

Powdered galls 6 parts. Menthol 1 " Crude petroleum jelly to 100 "

The "Muco-food Cones" had an average weight of 21 grains; analysis showed them to consist of:

Wheat flour 28 per cent. Oil of theobroma (cocoa butter) 68 " Water 4 "

Careful search failed to show any other ingredient.

The pills were coated with a mixture of talc and sugar, tinted an orange colour; after removing the coating they had an average weight of 1·1 grain. Analysis showed them to contain small quantities of powdered capsicum, powdered liquorice, and maize

starch; 23 per cent. of ash, about half of which consisted of silicious matter and was apparently talc that had got into the pill from the coating; the remainder of the ash showed the usual constituents of the ash of vegetable drugs and extracts, together with a small quantity of zinc, which was present in the pill in the metallic state and was presumably derived from some vessel used in the preparation; a bitter extract, agreeing in its properties with extract of cascara sagrada, constituting the major portion of the pill; and a resinoid substance which resembled iridin. As a definite formula cannot be given for such a pill, the cost of ingredients can only be estimated somewhat roughly. After making liberal allowance for the unknown resinoid, the estimated cost of the ingredients of the quantities of the three preparations supplied for 4s. 6d. is three-farthings.

CHAPTER XVIII.

PREPARATIONS FOR RUPTURE.

Advertisements of means of curing rupture without operation are very common, but in most cases the advertiser has for sale a special form of truss or other appliance. The disorder is so well-known to be of a mechanical or structural nature, that it might have been thought that it would hardly have been worth anybody's while to advertise drugs for its cure. Nevertheless there are, at least, two instances in which medicine for internal or external use is supplied; the results of examination of these are here given.

RICE'S TREATMENT FOR RUPTURE.

The following is a specimen of the wording of the advertisement of this "treatment" which used to be, and perhaps still is, very commonly illustrated by a picture of a bricklayer filling up a hole in a wall:

RUPTURE CURED.

Do You See this Bricklayer Closing up the Opening in that Wall. That is the way to cure _Rupture_, by filling in the opening with _new_ and _stronger_ tissue.

A rupture is simply a break in a wall—the wall of _muscle_ that protects the bowels and other internal organs.

It is just as easy to cure a wound or break in _this_ muscle as one in the arm or hand.

Now this break may be no larger than the tip of your finger. But it is large _enough_ to allow part of the intestines to crowd through. Of course, this cannot _heal_ unless nature is _assisted_. That is just what this Method does. It enables you to retain the protrusion inside the wall in its proper place.

Then we give you a Developing Lymphol to apply on the rupture opening. This penetrates _through_ the skin to the edges of the opening and removes the _hard ring_ which has formed around the break.

Then the _healing_ process begins. Nature, no longer handicapped by the protruding bowel and hardened ring at the opening, and stimulated by the action of the Lymphol, throws out _her_ supply of lymph, and the opening is again filled with _new muscle_.

Isn't this simple? Isn't it _reasonable_?...

Simply _write_ us and we will post you a _free sample treatment of_ the Developing Lymphol and a finely illustrated book on The Nature and Cure of Rupture. Do _not_ send any money. Just your _name_ and _address_ on this Coupon.

Application for particulars of the method of cure brought a book of 40 pages, entitled "The Nature and Cure of Rupture," with a letter, directions for measurement, and other papers. It would seem that if the applicant does not at once become a customer, other letters and booklets are sent at intervals. The titles of some of these booklets which are before us are: "First Aid to the Ruptured," "The Value of a Cure," "A Fireside Reverie," "Facts and Faces," "The Story of Christopher Columbus," and "The Man Who Wondered Why." However much the matter varies, it always leads to the subject of the cure of rupture by Rice's Treatment. The treatment consists of the wearing of an "Appliance" (occasionally referred to as "my perfect truss") and the application of "Developing Lymphol." The respective parts stated to be played by these are indicated by the following extracts from some of the pamphlets referred to:

To be cured of rupture it is necessary to apply my Lymphol Developing Treatment regularly as directed, for it is the Lymphol, not the Appliance, that performs the cure.

The Appliance is simply a means of support to retain the rupture, and prevent the protrusion from tearing down the new particles of tissue with which the opening is being filled under the vitalizing and healing influence of the Lymphol.

The appliance is supplied in two grades or qualities. The price of the Appliance and Lymphol together ranged from 21s. for a child's single appliance of the cheaper grade to £4 10s. for an "Abdominal Supporter and Navel Appliance Combined," of the higher grade. It was stated in the price list that the lymphol and appliance were not supplied separately; but in another list sent with the goods the lymphol alone was priced at 16s. 6d. The bottle sent held just over four fluid ounces.

The directions were:

Lie on your back, remove appliance, unscrew stopper, and sprinkle a few drops of the Lymphol on to the point where the rapture leaves the cavity of the abdomen. Apply night and morning, rubbing in thoroughly with fingers. If irritation is produced, use less Lymphol, or discontinue its use for a few days. The Lymphol may be reduced in strength by adding Spiritus Rectificatus which can be obtained from any chemist.

The "appliance" consisted of an elastic band to go round the body, fitted with an adjustable pad and an understrap. Analysis showed the "lymphol" to be an alcoholic solution containing essential oils and capsicum resin, and a trace of red colouring matter. Oils of origanum (thyme), peppermint, and spearmint were recognized; the proportion of capsicum was estimated by determining the total solid matter, and by comparing the pungency of dilutions of the lymphol with dilutions of the solutions prepared in imitation; the red colouring matter was not cochineal, or one of the common vegetable colours, but appeared to be one of the artificial dyes. Careful comparisons indicated the following formula:

Tincture of capsicum (_B.P._ strength but prepared with strong alcohol) 60 parts by measure. Oil of origanum 6 " " Oil of peppermint 1 " " Oil of spearmint 0·3 " " Red dye q.s. " " Rectified spirit to 100 " "

The estimated cost of the ingredients for 4 fluid ounces is 9d.

HEALINE TREATMENT.

This is advertised from a town in the south of England as follows:

Rupture cured

speedily and permanently, with inexpensive home treatment. A certain remedy for Man, Woman, and Child. Full particulars on receipt of two stamps.

Application to the address given brought a booklet of 28 pages, headed:

The following is a description of Rupture, Its causes, Symptoms, Treatment, and Cure.

An extract from this booklet is here given:

The only possible way to effect a permanent cure is by taking a remedy that will fortify and strengthen the weakened vessels, and so enable them to bear an ordinary strain without injuring them. HEALINE TREATMENT No. 1 has been found by experience to perform this operation after all other so-called treatments have failed. External treatment cannot cure you, for the cause is internal; therefore to effect a cure the cause must be removed. By taking this remedy as directed, a cure may be expected from two to four months, according to description of complaint and length of time affected. From six to nine bottles of this preparation is generally sufficient to effect a cure, or the same quantity of pills. I do not guarantee to completely cure every case, but it will do as much good as nature will allow, and prevent strangulation in every case. I find, after a few years' experience with this remedy, that it is able to absolutely cure ninety out of every hundred cases of rapture, where nine to a dozen bottles have been taken.

Other sections of the pamphlet are devoted to varicocele and varicose veins, for which it appears that "Healine No. 2" and "Healine No. 3" respectively are recommended.

The prices of the preparations (post free) were thus given:

Liquid Form.—3s. per bottle; Three for 8s. 9d.; or Six prepared bottles for 15s.

Pill Form (recommended).—2s. 9d. per box; Three for 8s.; or Six for 13s. 9d.

Healine Lotion (same price as Internal Healine) is always necessary for bad Ulcerated Legs and open or deep-seated Wounds, and never fails to cure when used as directed.

Consultation by appointment only, for which a fee of 2s. 6d. will be charged.

An application for a bottle of liquid “Healine No. 1,” with a remittance of 3s., brought in return a box of the pills, with an intimation that these were recommended in preference. The box contained 60 pills, two to be taken three times a day.

The pills were coated with talc, after removal of which they had an average weight of 4 grains. No metallic salts were present, and no alkaloid; about 1 per cent. of an oily liquid of acid nature, apparently oleic acid, was found; small quantities of a tannin, gum, and phlobaphene, a decomposition product of tannin, were present, and a bitter substance which showed no characters by which it could be identified; aloin and extract of cascara sagrada were absent, and all resinous substances, unless in minute quantity; the pill consisted chiefly of indefinite extractive, with about 20 per cent. of a vegetable powder, one ingredient of which was liquorice, a second appearing to be gentian, but it was not identified with certainty; a considerable portion of the vegetable powder had no identifiable properties.

CHAPTER XIX.

CURES FOR INEBRIETY.

For a good many years past cures for inebriety have been freely advertised in various ways, some of them commonplace and others showing a good deal of ingenuity. Some are advertised and sold in the same way as ordinary secret remedies, that is to say, the purchaser sends so much money and receives a box or bottle with directions for administering the contents. In other instances the inebriate is required to submit himself to inspection, and in certain cases must enter a home maintained by the proprietor or his agents. Between these two extremes there are intermediate plans, the methods followed shading off on the one hand into those of the ordinary nostrum seller, and on the other into the more elaborate system of the “treatments” with which transatlantic enterprise has made us familiar. The last of the remedies described by name below approximates very closely to this class.

COZA POWDER.

This powder is supplied by the Coza Institute, 76, Wardour Street, London, W., formerly 62, Chancery Lane, London, W.C. The price charged for a box, containing 30 powders was 10s.

The preparation was advertised with an offer of a free sample. An application for a sample brought a single powder together with a 10s. box to be paid for or returned, a book of 130 pages (which is referred to below), and a letter, from which the following is an extract:

Coza Powder has the marvellous effect of producing a repugnance to intoxicating drink of any kind, and may be administered in coffee, tea, milk, water, beer, whisky, brandy, or solid food without the partaker’s knowledge.

Coza Powder does its work so silently and surely that any person interested in the intemperate can administer it to him or her without his or her knowledge and without him or her learning what has effected the reformation.

Coza Powder has reconciled thousands of families, saved from shame and dishonour thousands of men and transformed them into sturdy citizens and capable business men. It has led many a young man along the direct road to good fortune, and has prolonged by several years the lives of many individuals.

We particularly wish to draw your attention to the fact that we guarantee Coza Powder to be absolutely harmless.

The book which was sent, entitled _No more Drunkenness_, opens with the statements that—

Coza Powder is one of the greatest discoveries of the day. There is nothing in the whole world to compare with it. It is the only powder to cure the craving for drink and drug habits.

The first few pages are devoted to a disquisition on drunkenness; then follow further claims for Coza Powder, such as—

Coza is the name of a marvellous powder which possesses the quality of occasioning in him who takes it a dislike for alcoholic liquors and all intoxicating drinks. The drinker finds alcohol so detestable that even on the most tempting occasions it will be

impossible for him to take a single drop.

A large part of the book is given up to what are called testimonials, with portraits stated to represent the writers; the large majority of these are dated from Continental countries. Those to which English names and addresses are appended are for the most part expressions of hopefulness, or records of slight variations in drinking which are believed to be due to the powders; for instance:

My friend has been taking “Coza” this last two days, and he has had no desire for drink.

Enclosed you will find P.O. for which send me another box. I think the powders are doing my friend good. Send at once.

The last pages of the book are devoted to advertisements of Canexia Hair Elixir, Canexia-Brilliantine, and Canexia-Shampoo Powder, supplied from the Canexia Chemical Works, 61, Chancery Lane; and Anticelta Tablets for Obesity, and Brixa Tablets for Thin People, supplied from 62, Chancery Lane.

A visit to the address showed that the Canexia Chemical Works, the Coza Institute, and the offices of Anticelta and Brixa Tablets were all at that time accommodated in three rooms on the second floor at 61 and 62, Chancery Lane, the double number representing the one entrance of a large block of buildings containing hundreds of different offices. A photograph of the entire block, inscribed “Coza Institute,” is given in the book just referred to. The address has since been changed to that given above.

The powders had an average weight of 1½ grains, the weights of single ones varying from ■ grain to 3 grains. Analysis showed them to contain 90·5 per cent. of sodium bicarbonate, the remainder being a vegetable powder; microscopic examination of this powder showed that it agreed in all its characters with a mixture of equal parts of cummin fruit and cinnamon. No alkaloid was present, and no other ingredient of any kind could be detected. The formula is thus:

Sodium bicarbonate 90 parts. Powdered cinnamon 5 ” Powdered cummin 5 ”

Cummin fruit (seeds) have a bitter aromatic taste and a peculiar strong heavy odour. Owing to its disagreeable taste and odour cummin is seldom used in medicine, any medicinal properties it possesses being the same as those of other aromatic and less nauseous umbelliferous fruits.

The estimated cost of the ingredients for 30 powders was one-thirtieth of a penny.

DIPSOCURE.

This nostrum is prepared by a “Chemical Co.,” giving an address in Birmingham. The price charged for a box, containing 50 powders, 25 being white and 25 tinted reddish-buff, was 9s.

This article, like the preceding, is advertised with an offer of a free sample. Application for a sample brought also a stream of letters at short intervals, with abundant printed matter. A few extracts from the letters are here given:

Eminent medical men have over and over again declared that if a cure for drunkenness could be discovered both TASTELESS AND ODOURLESS, and placed in the hands of a devoted woman to administer SECRETLY, the greatest difficulty in effecting cures would have been overcome. “Dipsocure” IS TASTELESS and ODOURLESS, and CAN BE administered SECRETLY; so that it has been our privilege and good fortune to have solved the problem. Whilst counteracting and freeing the alcoholic-laden system of the poison, it is soothing to the nerves and restores the health, and is harmless to the most delicate person.

... when a cure has been effected we ask you kindly to acquaint us of the fact, and perhaps you will then consider our agency proposal, showing how a good income can be made by introducing the cure to others. To show you the ease with which it can be sold, if you remit us 10s. three packages will be sent, two of which you can readily dispose of to other sufferers at 9s. each, thus making 8s. profit and obtaining one packet quite free.

The directions for use were:

Give one powder three times a day, before meals, dissolved in half a tea-cup of Hot Coffee, Tea, Whisky, Milk, Gin, &c.

Use either the brown or white powder, as the colour of the liquid may require.

The powders had an average weight of 4·2 grains, single powders varying from 2·9 to 6·0 grains. The composition of both kinds was found to be the same except for the trace of colouring matter contained in the tinted powder. Analysis showed the composition

to be—

Acetanilide 6 parts. Potassium bromide 35 ” Sugar of milk 59 ”

The estimated cost of the ingredients for 50 powders was one-third of a penny.

ANTIDIPSO.

This is supplied by another “Chemical Company,” giving an address in London. The price of a box, containing 48 powders, 24 being white, and 24 tinted pinkish-buff, was 10s.

The statements made about this article, in circulars and letters, were very similar to those made about the preceding one. A few extracts will suffice:

You will not forget that to insure an absolute complete and permanent cure for the craving, two boxes are invariably required. We have had data of cures effected with one box, but to make absolutely sure you will do well to immediately send us remittance, to the same value as the last, and get the second box of the specific. Antidipso may be administered with or without the knowledge of the patient.... We enclose you a booklet showing our agency terms. Kindly give it your attention, as we are confident you will be so surprised and satisfied at the cure which will be effected that you will either yourself want to take up agency with us, or get some one in your district to do so.

The directions were:

Give one powder, dissolved in half a tea-cup of hot coffee, whisky, milk, gin, &c. (using either Brown or White Powder as colour of liquid may require) 3 times a day before meals.

The powders had an average weight of 5·3 grains, single powders ranging from 3·7 to 9·9 grains. The white and tinted powders were made of the same constituents, with a trace of colouring matter added in the latter case, but in different proportions. Analysis showed the composition to be:

WHITE POWDERS.

Potassium bromide 24·5 parts. Sugar of milk 75·5 ”

COLOURED POWDERS.

Potassium bromide 35 parts. Sugar of milk 65 ”

The estimated cost of the ingredients for 48 powders was one-third of a penny.

THE TEETOLIA TREATMENT.

The following is an extract from an advertisement of a “Teetolia Treatment Association,” giving an address in London:

After years of Drink and Drug taking—

Cured in 4 days.

... The Teetolia treatment acts so rapidly and so efficiently that within four days from the commencement of administration the insistent craving for drink is absolutely destroyed—so much so, that even the thought of alcohol becomes nauseating.... Thousands have been cured by this treatment, and we guarantee to cure you. If you write to-day, you will receive by return of post a private consultation sheet, together with a valuable book on this subject, post free in plain envelope, and you will be a free man within a week.

On application being made for further particulars, a booklet of twenty pages, entitled _The Teetolia Treatment for Alcoholic Excess, Drug Habits, and Resultant Nervous Diseases_, was sent, together with a letter and a form to be filled up with particulars of the case to be treated. The following are extracts from the booklet:

The discovery of the Teetolia method and treatment for the permanent eradication of the crave for drink and drugs marks an era in medical science. It is the outcome of a life’s study of the subject by one of our best known West-End physicians.

You can, whilst undergoing the treatment, pursue your ordinary methods of living. You continue to take your daily modicum of alcohol; but somehow about the third or fourth day of treatment, without having made any physical or mental effort, you feel that you no longer want a drink; it holds out no attractions to you; its magnetic influence has gone....

We are willing to supply you with sufficient medicine for eight days' treatment free of all charge. This will enable you to determine whether the treatment is acting successfully, for at the end of the fourth day an obvious and perceptible effect should be experienced. We impose no condition; we rely on your candour, honesty, and gratitude that at the end of the eight days' treatment, if you are convinced of the value of the Teetolia Treatment, you will forward to us the ordinary fee—£1 1_s._—for same, but if you have derived no benefit from the treatment at the end of the same period, then you are under no obligation whatever to pay us one single penny.

The letters were on headed paper, at the top of which was printed, "All communications strictly confidential," and "Consultations with Physician by appointment." The first letter concluded as follows:

Please therefore fill in and return without delay the special statement sheet and upon our receiving it the Physician will go carefully into the case and will prescribe special medicine, which will reach you with expert advice in the course of two or three days in a perfectly plain sealed package.

The "expert advice," in a letter purporting to be from "The Medical Superintendent," sent with the medicine, contained these passages:

I want, if possible, the patient to use his own endeavours to try and keep off alcohol during the first few days of treatment; if this cannot be done, then the treatment must be commenced when the patient is not drinking, in order to give the medicine a better hold on the system. The dislike for alcohol, which we claim, does not come on all at once.

The eight days' treatment is enough to show you that it will do good, but not sufficient in this case to effect a permanent cure. I would advise the patient to continue for at least a month to six weeks.

This is somewhat widely at variance with the statements quoted above. "You continue to take your daily modicum of alcohol" and "you will be a free man within a week."

The one guinea "treatment" consisted of 2■ fluid ounces of a liquid of the nature of a vegetable fluid extract.

The directions were:

Half a teaspoonful to be taken in a little water every four hours during the day at 10, 2, 6, and 10 o'c.

Analysis showed this to contain 29·3 per cent. by volume of alcohol and 2·3 per cent. of alkaloid, which consisted principally of quinine. The liquid agreed generally with a diluted liquid extract of cinchona; the amount of alkaloid was just under half what is contained in the official liquid extract of cinchona. Treatment with suitable solvents extracted a trace of a non-alkaloidal bitter substance resembling the bitter substances obtainable from quassia, chiretta, &c.; a preparation of chiretta appeared to be the more probable. No strychnine was present, and no evidence was obtained of any other ingredient.

SOME OTHER DRUG CURES FOR INEBRIETY.

A somewhat frequent constituent of preparations for the treatment of inebriety is atropine, while other preparations contain one or more of the alkaloids belonging to the same group, usually known as the solanaceous alkaloids from the fact that they are all derived from plants of the nat. ord. _Solanaceae_. These alkaloids closely resemble each other in their chemical nature and in their pharmacological properties; the principal members of the group are:

Atropine, C■■H■■NO■; obtained chiefly from _Atropa belladonna_ (deadly nightshade) and _Scopola carniolica_.

Hyoscyamine, C■■H■■NO■, obtained chiefly from _Hyoscyamus niger_ (henbane) and _Scopola_ species.

Hyoscine, or scopolamine, C■■H■■NO■, obtained chiefly from _Scopola_ species, _Hyoscyamus niger_, and _Datura alba_.

The two following were originally described as separate substances, but have more recently been shown to consist of mixtures:

Duboisine, obtained from _Duboisia myoporoides_, consists chiefly of hyoscyamine and hyoscine.

Daturine, from _Datura stramonium_ (thornapple) consists chiefly of hyoscyamine, with a variable proportion of atropine.

A certain preparation for inebriety is said to contain “stramonine”; as no alkaloid has been described and characterized under this name, it is probably only a variant of daturine, which, as has been said, consists of a natural mixture of hyoscyamine and atropine.

To the above may be added the artificial alkaloid homatropine (C■■H■■NO■), which has not been found in a plant, but is prepared synthetically; in chemical constitution it is mandelyl-tropeine, atropine being tropyltropeine.

The differences in the action of the four principal solanaceous alkaloids are briefly as follows:

Atropine has a stimulant action on the central nervous system especially on the motor area; it depresses and in large doses paralyses the nerve endings of secretory glands, plain muscle, and the heart.

Hyoscyamine is intermediate in its action between atropine and hyoscine; causes less stimulation of the central nervous system than atropine, and is a weaker sedative and hypnotic than hyoscine. It has the same action peripherally as atropine but is twice as powerful.

Hyoscine resembles atropine in its paralysing effect upon peripheral nerve endings, the action being quicker, more powerful, and less lasting. It does not possess the stimulating effect of atropine upon the brain; depression of the motor area is marked from the first.

Homatropine resembles atropine in its action but is less powerful.

CHAPTER XX.

CURE ALLS.

The greater number of the proprietary medicines described in these pages are advertised as cures for a wide range of ailments, but usually there is some one disease for the treatment of which they are particularly recommended, so that it has been possible to classify them according to their alleged purposes. In very many other cases, however, the claims made are so wide that the article is put forward as a sort of cure-all. Thus one of the articles described is stated to cure such different disorders as constipation, rheumatism, St. Vitus’s dance, heart disease, rickets, sleeplessness, kidney complaints, and women’s special ailments, among many others, and is said to be “a real elixir of life in solid form”; the facts as to its composition, ascertained by analysis, show what the possibility of its being a “cure”—for heart disease, for instance—is. As to “Pink Pills,” another of the nostrums analysed, which probably owes its popularity partly to bold advertisement and partly to its alliterative name, the method followed appears to be to recommend them for different diseases in different advertisements; personal testimony, or what is put forward as such, from sufferers who have been cured, is made the basis of most of these, and illustrations are employed to catch the eye of the casual reader. Analysis showed that these pills were practically the ordinary iron-carbonate pills commonly called Blaud’s pill, which ought to be freshly made. The Pink Pills are of lower strength than usually prescribed, and to judge by the proportion of iron that was found to be in the higher state of oxidation, very carelessly prepared. They differ vastly, however, from other Blaud’s pills in the price charged for them. Thus the proprietary Pink Pills are sold at a little over a penny each, while coated Blaud’s pills can be bought retail at a few pence a gross, and wholesale in large quantities at a little over a penny a gross. The analyses of other proprietary preparations show a similar disparity between the market price of the drug supplied and the price charged to the person who is beguiled into purchasing; thus thirteen-pence-halfpenny, two shillings and sixpence, and two shillings and ninepence are the selling prices of nostrums, the ingredients of which are estimated to cost respectively one-eighth, one-third, and one-tenth of a penny.

Preparations of this class are not in all cases very clearly marked off from those recommended for some special disease, such as have been dealt with in previous chapters, for many of them are recommended for some one disease, of which nearly all others are asserted to be variations.

DR. MARTIN’S MIRACLETTS.

These wonders are supplied by a Medicine Co., from an address in London. The prices are 1s. 1½d., 2s. 9d., 4s. 6d., and 11s. per bottle. A 2s. 9d. bottle contained sixty tablets.

They are described on the package as:

A real Elixir of Life in solid form. The world's greatest remedy.

Cures Constipation, Indigestion, Headache, Neuralgia, Anæmia, Nervous Disorders, Liver Troubles, Rheumatism, Sciatica, Gout, St. Vitus' Dance, Hysteria, Rickets, Heart Disease, Kidney Complaints.

Cures Melancholia, Loss of Appetite, Sleeplessness, Lassitude, Mental Depression, Brain Fag, Palpitation, Stomach Disorders, Women's Special Ailments and Irregularity of Health, etc., etc.

A little book, entitled "A Fortune for All," enclosed in the package, contained the following statements:

Whatever you may be suffering from do not worry or fear, as Dr. MARTEN'S MIRACLETTS will be certain to cure you!

Dr. Martin's Miracletts make the weak and sickly become strong and healthy, and the aged become youthful and full of energy; the tired worn-out look being replaced by an appearance of cheerfulness and vivid health. The pale and wrinkled face with bad complexion gives way to rosy cheeks and a clear skin; the thin gain flesh, and the stout lose superfluous fat; indigestion quickly disappears, the appetite returns, and a _new life_ is open to all.

A separate small slip enclosed in the package was worded as follows:

GUARANTEE.

Dr. Martin's Medicine Company being absolutely confident of the marvellous curative properties of their Miracletts, will willingly refund the money to any purchaser who has taken eighteen Miracletts according to directions, and is not satisfied with the results.

Much less conspicuously, on another slip chiefly devoted to the relative quantities in the packages of different size, it was stated:

Those whose ailments have been of long standing must not expect immediate perceptible results, but with a little patience and perseverance the result is SURE.

The "Miracletts" consisted of sugar-coated tablets, the coating being coloured brown with ferric oxide (so-called chocolate coating). After removal of the coating they had an average weight of 4·3 grains; this included the weight of a strong coating of varnish, which was not removed with the sugar-coating. Analysis showed them to contain valerianates of quinine and zinc, iron oxide, menthol, kaolin in considerable quantity, and a little talc. A substance of extract nature was also present to the extent of about 5 per cent.; it possessed no characteristic taste or other property by which it could be identified; a resinous substance, which was found in small quantity, appeared to be merely the varnish with which the tablets were covered. The quantities of the different ingredients were determined as nearly as possible, and the results indicated the following amounts:

Quinine valerianate 0·4 grain. Zinc valerianate 0·1 " Ferric oxide 0·3 " Menthol 0·03 " Kaolin and talc 2·3 grains In one tablet.

The estimated cost of the ingredients of the tablets is 4d. a hundred.

THERAPION.

Another "medicine company," also with an address in London, advertises three preparations which it calls Therapion. Therapion No. 1 was described as "the most efficacious remedy" for "all discharges"; Therapion No. 2 as "the great remedy for impurity of the blood, scurvy, pimples, spots, blotches, pains and swellings of the joints, gout," and so on; and No. 3 as a new French remedy, by the use of which the shattered health will be restored.

The Expiring Lamp of Life Lighted Up Afresh,

and a new existence imparted in place of what had so lately seemed worn, "used up," and valueless. This wonderful medicine is suitable for all ages, constitutions, and conditions, in either sex, and it is difficult to imagine a case of disease or derangement, whose main features are those of debility, that will not be speedily and permanently benefited by this never-failing recuperative essence, which is destined to cast into oblivion everything that had preceded it, for this widespread and numerous class of human ailments.

The claims for No. 3 being so inclusive, it was deemed sufficient to analyse it only. The dose of all three was stated to be the same—a piece about the size of a small marble three or four times a day; as the package, costing 2s. 9d., contained 1■ oz., and as it was referred to as providing twenty ordinary doses, a single dose would be about 30 grains. The substance consisted of a dark

stiff paste smelling strongly of camphor. Analysis showed it to contain, in addition to camphor, glycerine, powdered liquorice, a bitter extract agreeing in all respects with extract of gentian, calcium glycerophosphate, and a trace of alkaloid; there also appeared to be a second extract present. The alkaloid, which amounted to 0·06 per cent. only, could not be identified with any of the ordinary medicinal alkaloids. There was some evidence that the second extract was that of damiana, and a paste made up with this and the other ingredients agreed well with the original; but extract of damiana possesses no distinctive characters by which it can be identified in a mixture. Quantitative determinations were made of those ingredients capable of it, and the proportions of the others estimated by comparison. The results indicated the following formula:

Camphor 2·5 parts. Glycerine 24 ” Powdered liquorice 40 ” Calcium glycerophosphate 1·8 ” Extract of gentian 5·0 ” Extract of damiana (?) 8 ” Alkaloid 0·06 ” Water to 100 ”

In addition, there appeared to be present a slight trace of the oil of one of the umbelliferous fruits, probably anise or fennel. Disregarding the trace of alkaloid, the estimated cost of the ingredients for 1■ oz. is 2d.

PINK PILLS FOR PALE PEOPLE.

These pills, sold by the Dr. Williams Medicine Company, from an address in London, are stated to be manufactured in the United States of America. The price is 2s. 9d. a box, containing 30 pills.

The pills are advertised for a great variety of diseases, prominence being usually given to one disease in each advertisement; thus four long advertisements appearing simultaneously in different papers were respectively headed:

Afraid of being touched. So sore with Rheumatism. A once-crippled victim tells how Dr. Williams’ Pink Pills cleansed his system of Rheumatism.

Eczema expelled. Mr. John Chamberlain tells how his sufferings from Skin Disease were cured by Dr. Williams’ Pink Pills.

Sciatica’s Swift Pains rendered this Lady helpless. Her case had defied treatment, but Dr. Williams’ Pink Pills succeeded by curing the cause of Sciatica.

The Dark Days of Dyspepsia.... Dr. Williams’ Pink Pills go to the very cause of the mischief.

Each advertisement included a long description of a “case,” and as a rule a picture was introduced. The following is from the concluding paragraph of the first of these advertisements, and the others ended in a similar way.

THE DR. WILLIAMS’ WAY.

When the muscles and nerves are tortured by poisons in the Blood, be the result Rheumatism, Sciatica, or Lumbago, the only way to a cure is to Enrich and Purify the Blood. Dr. Williams’ Pink Pills, in this way alone, have cured not only Rheumatism, but Anæmia, Indigestion, Palpitations, Influenza’s After-Effects, Eczema, Sciatica, St. Vitus’ Dance, Spinal Weakness, the many forms of Nervous Disorders dreaded by men; also the special ailments of women.

The pills were ovoid in shape and coated with sugar, coloured pink; after removal of the coating they had an average weight of 3 grains. Analysis showed them to contain ferrous sulphate, potassium carbonate (these two having reacted more or less completely, and about one-third of the iron having become oxidized to the ferric state), magnesia, powdered liquorice, and sugar. Since it has been stated that these pills contain arsenic, careful search was made for it, but it was not found, The pill is thus merely one of the many variations of Blaud’s pill. The quantities of the different ingredients found indicated the following formula:

Exsiccated sulphate of iron 0·75 grain. Potassium carbonate, anhydrous 0·66 ” Magnesia 0·09 ” Powdered liquorice 1·4 ” Sugar 0·2 ” In one pill.

The estimated cost of the ingredients for 30 pills is one-tenth of a penny.

BEECHAM’S PILLS.

A box of these pills, advertised to be worth a guinea, is sold for 1s. 1½d., and the prime cost of the ingredients of the 56 pills it contains is about half a farthing.

In a circular wrapped round the box it is stated that “these renowned pills are composed entirely of Medicinal Herbs,” and cure Constipation, Headache, Dizziness or Swimming in the Head, Wind, Pain, and Spasms at the Stomach, Pains in the Back, Restlessness, Insomnia, Indigestion, Want of Appetite, Fullness after Meals, Vomitings, Sickness of the Stomach, Bilious or Liver Complaints, Sick Headaches, Cold Chills, Flushings of Heat, Lowness of Spirits, and all Nervous Affections, Scurvy and Scorbutic Affections, Pimples and Blotches on the Skin, Bad Legs, Ulcers, Wounds, Maladies of Indiscretion, Kidney and Urinary Disorders, and Menstrual Derangements.

The pills had an average weight of 1¼ grains, and analysis showed them to consist of aloes, ginger, and soap; no other medicinal ingredient was found. The quantities were approximately as follows:

Aloes 0·5 grain. Powdered ginger 0·55 ” Powdered soap 0·18 ” In one pill.

NERVLETTES.

Of these pills, which are sold in a bottle, price 1s. 1½d., containing 27 pills, a circular enclosed in the package said

Coleman’s Nervlettes or Nerve Pills generate brain and nerve-force.

The pills were coated with talc; after removal of the coating they had an average weight of about 1½ grains. Analysis showed them to contain free phosphorus, quinine sulphate, a little powdered liquorice, and about 20 per cent. of a powdered vegetable tissue, which could not be identified; the remainder of the pill appeared to be of the nature of excipient only. The amounts of phosphorus and quinine were determined, and indicated the following formula:

Phosphorus 0·005 grain. Quinine sulphate 0·07 ” Vegetable powder 0·3 ” In one pill.

MOTHER SEIGEL’S CURATIVE SYRUP.

The price of a bottle of Mother Seigel’s Syrup containing 3 fluid ounces is 2s. 6d.

Although this was described on the wrapper as “for dyspepsia” so many disorders were stated to be due to this cause, and amenable to treatment with this preparation, that it may fairly be included in this chapter. On the other side of the wrapper it was called “A cure for impurities of the blood,” and “A cure for dyspepsia and liver complaints.” In a circular enclosed with the bottle it was stated:

The symptoms mentioned above are the smoke of the fire of indigestion—a fire that will eat out your very vitals and sap your strength and vitality. For it can’t be too often repeated that indigestion is the root of a great deal of evil; the origin of a great many disorders which no man quite understands how he came by. And why this is can easily be explained. Disease is poison; its symptoms are the manifestation of the poison. Indigestion creates many dangerous poisons, and is therefore the cause of many diseases.

So let us get rid of the smoke by putting out the fire, and purify our blood and system with Mother Seigel’s Syrup, which will sweep away the poisons and make us healthy and strong.

Mother Seigel’s Syrup is a highly concentrated, purely vegetable compound, having a specific action on the stomach, liver, and kidneys.

Analysis showed the presence of free hydrochloric acid, which is not usually classified as a vegetable compound, tincture of capsicum, a bitter substance agreeing in its properties with aloes, and sugar (partly as invert sugar); the colouring and flavouring substances also present indicated that the sugar had been added in the form of treacle. Quantitative determination of those ingredients capable of it, and estimation of the others by comparison with known mixtures, indicated the following formula:

Dilute hydrochloric acid (_B.P._) 10 parts by measure. Tincture of capsicum 1·7 ” ” Aloes 2 parts. Treacle 60 ” Water to 100 parts by measure.

The estimated cost of the ingredients for 3 fluid ounces is one-third of a penny.

THE ILLS OF HUMANITY.

Several examples have been encountered in previous chapters of the system of getting into personal communication with a possible customer, and addressing to him a series of letters warning him of the dire consequences should he fail to purchase the advertiser's "treatment." Over and beyond the chance of frightening the customer, the system, which seems to have originated in the United States of America, has the advantages that a profession can be made of adapting the treatment to the individual case, that the price may be lowered if the charge first made is considered too high and that possibly, in return for this concession, testimonials and the names of other sufferers may be obtained. A letter-writing system of this kind is found at work behind the advertisement from which the following paragraphs are extracted:

Free! Free!

To the Sick and Ailing Everywhere.

The Cure for your Disease—Delivered Free—Free for the Asking—Free to You.

To the sick—the suffering—to every man and woman victim of organic disease—local trouble or broken general health—Dr. Kidd's offer of free treatments is given in the absolute faith and sincere belief that they can and will stop disease, cure it, and lift you up again to health and vigour....

Rheumatism, kidney trouble, Bright's disease, diabetes, heart disease, partial paralysis, bladder troubles, stomach and bowel troubles, piles, catarrh, bronchitis, weak lungs, consumption, asthma, chronic coughs, nervousness, all female troubles, lumbago, skin diseases, scrofula, impure blood, general debility, organic vital ailments, etc., are cured to remain and continue cured....

Will you let me do this for you—will you let me prove it—brother and sister sufferers? Are you willing to trust a master physician, who not only MAKES this offer, but PUBLISHES it and then sends the test and proof of his remedies without a penny of cost to anyone except himself?...

My home office is at Fort Wayne, Indiana, U.S.A., but for the benefit of my thousands of English patients, I have established an office in London. Please address Dr. James W. Kidd, "Box" No. ____, E.C.

The advertisement was illustrated by the portrait of a man who, it might be assumed, was the "master physician" in question, but that in a book of some hundred pages, entitled "The Ills of Humanity, by Dr. James W. Kidd, Fort Wayne, Ind.," issued apparently by "the J. W. Kidd Co.," there is a portrait of Dr. James W. Kidd, which seems to represent a totally different person.

The book is principally occupied with a series of paragraphs on different complaints, rather over a hundred being dealt with; in the majority of cases the description leads up to reference to Dr. Kidd's treatment, or medicines, etc. Dr. James William Kidd, the book states, possesses a profound knowledge of medicine, a remarkable power over disease, and has "among his resources remedies that enable him to treat successfully many diseases that are generally considered incurable." After this the fact disclosed by analysis that his remedies seem in reality sadly lacking in originality and novelty, must excite a mild surprise.

It appears that persons writing to Dr. James W. Kidd, or the J. W. Kidd Co., receive a "Self-Examination and Consultation Blank." In one instance in which the blank was filled up, the reply was as follows:

Diagnosis and Case Record. By Dr. James W. Kidd, Fort Wayne, Ind.

For a complete description of your case, the probable results and my method of treatment, see pages 46, 99, 29, 13, 9, of the pamphlet "The Ills of Humanity," sent you under separate cover.

I find that you are afflicted with Rheumatism, Scrofula, Catarrh, Dyspepsia and Gastritis.

Rheumatism MEANS an excess of uric acid in the blood.

Scrofula is a constitutional disease almost synonymous with tuberculosis.

Catarrh is an excreting inflammation of the mucous membrane.

Dyspepsia (Indigestion) MEANS impaired secretion of pepsin and consequent imperfect digestion.

Gastritis MEANS catarrh of the mucous membrane of the stomach.

TAKE THE REMEDIES ACCORDING TO THE FOLLOWING DIRECTIONS:

One Tablet “A” before breakfast. One Tablet “B” before dinner. One Tablet No. 18 before supper. One Tablet No. 7 after dinner and after supper. One Tablet No. 45 on retiring.

This was accompanied by tablets marked “A,” “B,” and “18,” three of each, four marked “45,” and five marked “7”; also by a letter which appeared to be lithographed, and although the name and address were in the same writing and the same ink, they showed evidence of having been added afterwards. It seems probable, therefore, that, although professing to be a personal letter, it was one in regular use. It stated that Dr. James W. Kidd has “to-day selected and will forward to your address upon receipt of your remittance of 1_l._ the complete course of treatment,” the tablets sent being only samples. The letter apologizes for the smallness of the samples on the ground that the drugs “are very expensive.” The writer adds: “I have taken special interest in your case, because I want a cured patient in your immediate vicinity.” The tablets were analysed as completely as was possible with the small quantities sent, with the following results:

Tablet A (triangular) was coloured externally with a salmon-pink dye; the outer coating was of sugar, and below this was a rather thick coating of chalk, forming a very hard and resistant covering to the tablet. The decoated tablets weighed about 3-¼ grains each; they contained 52 per cent. of sodium bicarbonate, and the remainder consisted principally of a bitter extract agreeing in all respects with extract of gentian; small quantities of potato starch and a substance of resinoid nature, which could not be identified, were also present. No other medicinal substance could be found.

Tablet B (triangular) was coloured externally with a bluish-purple dye; the coating and the material of the tablets agreed in all respects with Tablet A, and the two were apparently identical.

Tablet 18 (circular) was white; the coating was of similar composition to that of A. The decoated tablets weighed about 3·8 grains each; analysis showed the presence of about 1 grain of sodium benzoate in each, together with a small quantity of a greenish, moderately bitter resin which could not be identified, and a trace of oil of wintergreen. Faint indications were obtained of a trace of an alkaloid, but not enough to amount to positive evidence. No other medicinal substance could be found; the remainder was of “extractive” nature.

Tablet 45 (circular) was coloured externally with a pink dye; the coating was of similar composition to that of A. The decoated tablets weighed about 1·1 grain each; the chief constituent was aloes, and there was also present a very small quantity of ginger extract, and a small quantity of a resin, which was probably jalap or scammony resin; also a moderate trace of alkaloid, which was not the alkaloid of nux vomica, belladonna, or hyoscyamus, but was not present in quantity sufficient to be identified; the only other ingredient found was a little potato starch.

Tablet 7 (circular) was not coated. The average weight of these was 6·5 grains each, and they consisted principally of charcoal, with some sugar and a very little saccharin.

“These special remedies are very expensive!”

BURGESS’S LION OINTMENT.

The results of an examination of Burgess’s Lion Ointment may be given here inasmuch as it will be seen that it is recommended for the cure of a great number of disorders. It is supplied in boxes at 1s. 1½d., 2s. 9d., 4s. 6d., 11s., and jars at 22s.; the 1s. 1½d. box contains 1 oz., and the next size 3 oz.

A circular wrapped round the box was headed “Amputation avoided—the knife superseded,” and continued:

E. Burgess’s Lion Ointment and Pills Have deservedly become the popular remedies for curing all diseases of the Skin, Old Wounds, Ulcers, Abscesses, (including Tuberculous), Tumours, Polypuses, Piles, Fistulas, Shingles, Venerea Sores, Whitlows, Broken Breasts, Bad Legs, Boils, Scurvy, Scrofula (_King’s Evil_), Scorbutic Eruptions, Poisoned Wounds _of all kinds_, Stings, Venomous Bites, Scurf, Ringworm, Itch, Corns, Chilblains, Chapped Hands, Cracked Lips, Cuts, Burns, Scalds, Gatherings in the Ear, Toothache, Earache, Neuralgia, Rheumatism, Gout, Sciatica, Quinsey, Bronchitis, Asthma, Deafness, etc.; also Ulcerous Affections of the Womb, for the treatment of which apply to the Proprietor, personally, or by letter, _in all cases free_. These invaluable medicines have not been introduced as remedies for any of the above complaints, or diseases, until they have in each case PRACTICALLY proved EFFECTUAL. To those who are suffering from diseases _apparently_ rendering amputation necessary, they are especially recommended, as they entirely do away with the necessity for the same by drawing all the cause of the disease from the affected part, cleansing the blood, and restoring the system to a sound, healthy condition.

They are vegetable preparations, and the Ointment can be applied with perfect confidence to the most tender skin. It is entirely free from all poisonous ingredients, a great recommendation for the nursery—for which it is invaluable.

In spite of the ointment being a “vegetable preparation,” analysis showed the principal ingredient to be lead oleate (lead plaster); this is blended with resin, wax, and fatty ingredients; vegetable extracts and active principles were found to be absent. It is not possible to separate the ingredients of an ointment like this sharply one from another; and, since the ingredients are not themselves simple bodies but mixtures liable to rather wide variations, they can only be approximately determined, and, as regards the lard and oil, even identification cannot be placed beyond doubt nor can small quantities of some other fats be certainly stated to be absent. These, however, are matters of minor importance. The composition given below has been checked by varying the analytical methods, as well as by comparison of various ointments prepared according to formulæ suggested by analysis. As a result of the investigation, the following formula was arrived at, which gives an ointment similar to the “Lion” ointment:

Lead plaster 13 parts. Beeswax 20 ” Resin 11 ” Olive oil 12 ” Water 6 ” Lard, to 100 ”

The estimated cost of the ingredients is about 1Od. per lb. of ointment.

APPENDIX.

STAMP DUTY ON SECRET REMEDIES.

The duty on secret medicines is regulated by the Stamp Act of 1804 as amended by the Stamp Act Amendment Act of 1812. The Act of 1804 was itself in part an amending Act and regulated the duties to be paid on paper, on books, on advertisements, and imposed _ad valorem_ duties on hats and proprietary medicines. The tax on proprietary medicines remains, but that on advertisements through and by which they continue to exist and flourish has gone the way of the duties on hats, and books, and paper. The Act of 1804 contained a schedule of medicines to the number of some 450. In the Act of 1812 this was replaced by a new schedule in which about 550 proprietary medicines were mentioned by name. The final clause of this Act, however, is expressed in very general terms, for it includes “all other pills, powders, lozenges, tinctures, potions, cordials, electuaries, plasters, unguents, salves, ointments, drops, lotions, oils, spirits, medicated herbs and waters, chemical and officinal preparations whatsoever, to be used or applied externally or internally as medicines or medicaments for the prevention, cure, or relief of any disorder or complaint incident to or in any wise affecting the human body,” if the person making or selling these various preparations claim to have any occult secret or art for making them or claim to have any exclusive right or title to make them, or prepares and sells them under the authority of letters patent, or if by public notice or advertisement, or by papers or labels on, or with, the enclosures, bottles, or cases in which the preparation is sold, the maker vendor, or proprietor recommend them as “nostrums, or as proprietary medicines, or as specifics, or as beneficial to the prevention, cure, or relief of any distemper, malady, ailment, disorder, or complaint incident to or in any wise affecting the human body.”

The Inland Revenue returns show that during the last ten years the amount received by the State from the stamp duty on patent medicines so-called has increased from £266,403 10s. 3d. in the year ending March 31, 1899, to £334,141 19s. 2½d. in the year ending March 31st, 1908. The net receipts are the gross receipts after deducting repayments and allowances, but the aggregates of these deductions are small. The following table shows the net receipts in each of the ten years, and the average for the two quinquennial periods, 1899-1903 and 1904-1908:—

TABLE SHOWING NET RECEIPTS FROM STAMPS ON “PATENT MEDICINES” FOR TEN YEARS, 1899-1908.

-----+---------- Year.| Yearly. |Quinquennial average. -----+---------- | £ s. d. | £ s. d. 1899 | 266,403 10 3 |} 1900 | 288,827 8 1½ |} 1901 | 297,479 19 6 |} 298,483 18 3 1902 | 306,337 5 9 |} 1903 | 333,371 7 9 |} | | 1904 | 323,445 14 0 |} 1905 | 331,438 17 6½ |} 1906 | 324,111 14 2 |} 328,048 16 0 1907 | 327,105 15 3½ |} 1908 | 334,141 19 2½ |} -----+----------

The value of the stamp which the vendor must affix to the bottle or package varies according to the price charged for the medicine, and the returns show the number of articles for which the several rates are paid. The following table gives the amount of the stamp duty on the several prices, the number of articles stamped in the fiscal year 1908, and the amount of the stamp. An attempt has also been made to estimate the total amount paid by the public for the articles stamped:—

TABLE SHOWING RATES OF DUTY, NUMBER OF ARTICLES STAMPED AND APPROXIMATE SUM PAID BY THE PUBLIC IN THE YEAR ENDING MARCH 31ST, 1908.

---------- Price of Article| Stamp. |Number of articles|Price paid by public. without stamp. | | stamped. | ---------- £ s. d. | s. d. | | £ s. d. 0 1 0 | 0 1½ | 33,037,202 | 1,858,342 12 0 0 2 6 | 0 3 | 7,565,822 | 1,040,300 10 0 0 4 0 | 0 6 | 1,002,549 | 225,573 10 6 0 10 0 | 1 0 | 122,249 | 67,236 19 0 1 0 0 | 2 0 | 18,445 | 20,289 10 0 1 10 0 | 3 0 | 11,308 | 18,658 4 0 ---------- 41,757,575 | 3,230,401 5 6 ----------

This estimate of the total amount paid by the public must be too high. In the first place it will be seen that the stamp duty does not rise by regular increments _ad valorem_. An article, the nominal price of which is 1s., must bear a stamp of 1½d., but if the nominal price be 1s. 6d., the stamp is 3d., and for an article of the nominal price of 2s. 6d. it is the same. In the second place, a large proportion of all the articles, probably the great majority of those at 1s., are sold at a discount, “store prices.” In the above table the maximum price for each rate of stamp duty and the full nominal prices are assumed. If a deduction of 25 per cent. is made to meet these sources of error, we have a sum of £2,422,800 19s. 1½d., as an estimate of the amount spent by the public on patent medicine in the financial year ending March 31, 1908.

At one time some of the vendors of nostrums took to inserting in their advertisements phrases intended to suggest that the Inland Revenue stamp upon their packages implied some sort of Government guarantee of the efficacy of the remedy. Though the Inland Revenue authorities do not as a rule display any anxiety with regard to the welfare of the public in the matter of the sale of nostrums, their efforts being confined to the collection of the duty, and the enforcement of the provisions of the Act should any vendor show a disposition to evade them, the stamp in recent years has borne the statement “This stamp implies no Government guarantee.” In spite of this vendors still sometimes contrive to convey the suggestion that the stamp conveys some sort of government guarantee; the suggestion looks the more plausible if the vendor has his name or autograph printed on the stamp by the government authorities; this will be done for him if he pays the cost of the die, and by the use of such an endorsement the incautious buyer may be led to assume that the Inland Revenue in some way shares the vendors’ responsibility for the genuineness of the article, that is to say for the genuineness of its claims. It has been suggested that the Legislature might go further and require the composition and ingredients of any secret remedy to be stated upon the label, box, or package, and looking to the nature of the facts disclosed by the analyses published in this book, it may well be believed that such publications on the labels would act to a certain extent as a warning to the public, for it would be apparent even to the least instructed that the claims in the vendors’ circulars were not quite consonant with the commonplace nature of the ingredients of the mixture, powder, pill, lotion, or ointment.

I.

In der Morgenstille war nichts vernehmbar als das helle, langgezogene Trillern der kleinen Buchfinken im jungen Birkenlaub. Die breite, ungepflasterte Straße, die sich, nicht weit von der russischen Hauptstadt, in der Richtung der finnländischen Bahnlinie ins flache Land erstreckte, lag einsam im Frühnebel da. Dann holperte ein Leiterwagen, mit einigen Möbelstücken bepackt, schwerfällig des Weges; der Fuhrmann kletterte von seinem Sitz, warf den kurzen Schafspelz von den Schultern, und, im roten Hemde neben seinen beiden magern Gäulen hergehend, stimmte er eine Volksweise an, die schwermütig in den Vogelgesang hineinklang.

Hinter den Birken tauchte hie und da ein Landhaus auf, meist ein Holzbau, mit geflossenen Fensterläden und bretterverschlagener Balkonthür; oder es schimmerte ein Garten hervor, in dem man eifrig beschäftigt war, das Winterlaub zusammenzukehren und die Beete für den Sommer in stand zu setzen. Aber erst nach Beginn der städtischen Schulferien wurde es in dieser Gegend lebendig.

Der Möbelwagen hielt vor einem Hause, das ganz abseits, weit entfernt von jeder Nachbarschaft, zwischen niedrigem Weidengebüsch und etwas feuchtem Wiesengrund lag. Es war nicht sonderlich groß, besaß aber den schönsten Garten von allen.

Die Frühlingsbäume, die es umstanden, breiteten einen zarten, bräunlichen Schleier darüber, und rings über den verwitterten Lattenzaun drängte sich der Flieder in hellgrünen Blattknospen.

»Die Pforte von außen aufstoßen!« schrie eine vergnügte Stimme in gebrochenem Russisch dem Fuhrmann entgegen, und gleich darauf kam ein halbwüchsiger Knabe durch den Garten gelaufen. Langsam bewegte der Wagen sich über den Kiesweg bis hinter das Haus, wo einige Stufen zur offenen Terrasse mit der Eingangsthür emporführten.

Eine ältliche Magd, mit einer sonderbaren Friesenhaube auf dem Kopf, wartete schon unten, griff kräftig mit an und ließ die abgeladenen Möbelstücke in dem Wohnzimmer niedersetzen, das mit seinem breiten Fenster auf die Terrasse hinaussah. Im Wohnzimmer stand die Thür zu einem kleinem Nebengemach auf, das bereits vollständig eingerichtet zu sein schien. Von den Sachen, die man, beim Auszug aus der Stadtwohnung, im gemieteten Landhause vorrätig gefunden hatte, war offenbar alles Beste und Bequemste hier zusammengetragen worden, um Ordnung und Gemütlichkeit zu schaffen.

An der Thür, auf einem deckenumhangenen Ruhebett, lag eine bleiche, nicht mehr junge Frau, deren feine Gesichtszüge jedoch Spuren ungewöhnlicher einstiger Schönheit zeigten. Unter halbgesenkten Augenlidern folgte sie aufmerksam jeder Bewegung der Kommenden und Gehenden.

Da vernahm sie von der Terrasse her eine Stimme, bei der ein Lächeln durch die großen blauen Augen ging.

»Erik!« rief sie bittend, »komm doch her zu mir. Komm doch her.«

Er stand vor dem Terrassenfenster, in dunkler Morgenjoppe, die Hände in deren Seitentaschen versenkt, zwischen den Zähnen eine Zigarette. Auf den Zuruf seiner Frau wandte er sich um und ging über den Flur in das Zimmer.

Ihr schien immer: ein Strom von Leben käme mit ihm, wenn er so zu ihr trat.

»Nun, Bel,« sagte er heiter, »du sollst sehen, jetzt bricht die Sonne durch den Nebel, und dann trage ich dich in den Garten hinaus. Deinen großen Liegestuhl haben wir schon dort hinten am Springbrunnen aufgestellt.«

Sie schüttelte den Kopf.

»Ich habe keine Ruhe draußen, solange hier alles noch in solcher Verwirrung ist. Wie mag es nur in deinen Zimmern aussehen, Erik? Seitdem wir gestern herkamen, habt ihr nur für mich gesorgt. Ach, weißt du, das ist das Schlimmste: im ganzen Leben wird nichts mehr recht ordentlich werden. Alles wird herumliegen.«

»Aber, Bel!« versetzte er spottend, »welchen Sinn hätte es auch sonst, aufzuräumen? Was sind das für Sorgen und Schmerzen!«

Doch Klare-Bel stimmte in den scherzenden Ton nicht mit ein, sondern sah betrübt vor sich hin. Da fügte er ungeduldig hinzu: »Damit mußt du dich ernstlich abfinden. Nicht immer wieder davon anfangen. Sicherlich bist du dazu geschaffen, als die peinlichste aller Hausfrauen hinter der blitzendsten aller Theemaschinen zu sitzen, und mußt nun statt dessen, jahraus, jahrein, daliegen und es unthätig mit ansehen, wie deine beiden männlichen Hausfrauen, Jonas und ich, es sorglos treiben. Das ist schwer, ich weiß. Es ist schwer, sein Talent zu unterdrücken. Aber es kann dir nicht erspart werden, du mußt es endlich überwinden.«

»Jonas könnte mir darin fast wie eine Tochter sein, Erik, wenn du nur wolltest.«

»Daß er wie eine Tochter ist? Nein, natürlich will ich das nicht. Wie kannst du nur solchen Unsinn sagen, Bel.«

»Es ist kein Unsinn, Erik. Du bist so streng gegen ihn, und daher ist er gegen dich oft schüchtern, geht nicht recht aus sich heraus. Aber mir zu dienen macht ihm Freude, -- auch in den häuslichen Dingen. Kannst du mir diese Freude nicht lassen?«

»Nein,« sagte er kurz, »nicht so, wie du es meinst. Ich wünsche nicht, daß er verweiblicht wird. An mir ist es, dir zu dienen --«

Er brach ab, weil die Magd hereintrat; sie wollte den Fuhrmann ablohnen.

Erik legte Geld auf den Tisch, der, noch staubig, in die Mitte der Stube gesetzt worden war.

»Dies ist das Trinkgeld, Gonne. Nein, es ist nichts darauf herauszugeben. Wenig genug für viel Arbeit.«

Als sie hinausgegangen war, blickte er mit einem unterdrückten Lächeln in den Geldbeutel und dann zu seiner Frau hinüber.

»Wir haben entsetzlich viel Geld, Bel. Natürlich. Wer sollte es uns auch in diesem Winkel abnehmen. Nicht wahr?«

»Ach, Erik, das kann doch gar nicht sein. In diesem ›Winkel‹ haben wir uns eins der teuersten Landhäuser ausgesucht. Ich habe ja nichts dagegen zu sagen gewagt. Aber wenn du wüßtest, wie es mich im stillen drückt. Denn du bist es ja, der seine ganze Kraft aufwenden muß, um das viele Geld zu verdienen.«

»Meine ganze Kraft aufwenden!« wiederholte er langsam, »wie schade ist es doch, Bel, daß es nicht wahr ist. Ich glaube fast, das wäre so schön, daß ich's sogar umsonst thäte! Es dürfte dann freilich nicht bei den paar armseligen Schulstunden bleiben. -- Nein, du, in diesem heiligen Lande vergesse ich bald, daß ich überhaupt Kraft anzuwenden ~habe~. Und da wollen wir uns doch wenigstens des Lebens freuen, wenn -- ich Geld habe. Sind wir nicht ganz eigens dazu vor einem halben Jahr hierher gepilgert?«

Sie hörte nicht die Ironie aus seinem Ton heraus.

»Nun ja, Erik, es ist nur gut, daß dir immer alles zu leicht und zu wenig scheint,« sagte sie, »du hast eine solche merkwürdige Frische. Aber ich wüßte doch wahrhaftig nicht, wo du beim besten Willen noch mehr Schulstunden hineinstopfen könntest?«

Ein Zug von Pein ging über sein Gesicht. Er antwortete nicht, sondern kehrte sich ab und lehnte sich in das breite Fenster des Wohnzimmers. Jonas war aus dem Garten hereingekommen, blieb neben dem Vater stehen und blickte hinaus.

Draußen kämpfte der letzte Nebel gegen die Maisonne; man konnte in der Tiefe des Gartens einzelne Obstbaumgruppen unterscheiden, in deren Mitte ein zusammengebrochener Springbrunnen stand. Im Hintergrunde schloß ein kleines Gehölz von Birken, Pappeln und Weiden, an denen noch die Kätzchen niederhingen, die Aussicht ab. Näher zum Hause streckten ein paar mächtige Ulmen ihre Zweige bis über das Dach.

Süß und laut schlug den beiden am Fenster die erste Nachtigall des Jahres entgegen. Einen Augenblick lauschten sie stumm.

Wie die Gesichter von Vater und Sohn einander so nahe gerückt waren, fiel die Aehnlichkeit zwischen ihnen auf; sie trat noch stärker dadurch hervor, daß Erik sich bartlos trug. Derselbe blonde Kopf, breit ausgebaut in Stirn und Schädelform, dieselbe ein wenig stumpf abschließende Nase und derselbe große, im Sprechen und Lachen sehr ausdrucksfähige Mund. Aber diese ein wenig groben Züge bedurften sichtlich mancher Jahrzehnte, um durchgeistigt und fesselnd zu wirken. Eriks Züge waren beredt geworden in all jenen feinen Linien und Schatten, die ihnen erst seelischen Reiz verliehen, als die Jugend von ihm ging. Jonas dagegen besaß noch ein frisches Apfelgesicht, das in seiner vollendeten Harmlosigkeit ihn oft minder geweckt erscheinen ließ, als er wirklich war. Schön konnte man an ihm nur die großen Blauaugen der Mutter finden, und deren blendende Haut, die nur das Krankenlager an ihr entfärbt hatte.

Klare-Bel lag still und blickte auf ihre beiden liebsten Menschen. In ihren Gedanken sah sie Jonas schon herangereift zu der hochgewachsenen Gestalt ihres Mannes; sie glaubte im Knaben ihn wiederzuerkennen, so wie er damals war, als sie ihn kennen lernte und er um sie warb. Es war ja auch gar keine so bedeutende Anzahl von Jahren, die ihn damals von Jonas' Alter unterschied -- einundzwanzig Jahre zählte Erik erst, als sein Knabe ihm geboren wurde. Sie fühlte jedesmal eine kleine Regung von Stolz, wenn sie daran dachte. Hatte er sich doch toll genug in sie verliebt, um sie, mitten in seiner leichtlebigen Pariser Studentenzeit, frischweg vom Fleck zu heiraten! Er, der begabte, ehrgeizige, früh weltmännisch geschulte Mann band sich an sie, das einfache Kinderfräulein, das nur der Glücksfall einer günstigen Stellung aus ihrer kleinen holländischen Vaterstadt Haarlem in die vornehmen Gesellschaftskreise von Paris geführt hatte. Die fremden Kinder an der Hand, hatte sie bewundernd in den Salon gelugt, in dem er verkehrte. Später gingen sie von Paris nach Deutschland und nach England und lebten ein paar Jahre von dem ganz geringen Vermögen, das schnell verbraucht war. Eriks Studien waren breit angelegt gewesen, sie sollten Geistes- und Naturwissenschaften gleichmäßig umfassen, aber als Jonas zwei Jahre alt wurde, da galt es, sich mit eisernem Fleiß zu konzentrieren und abzuschließen, um Brot zu erwerben. Eine kleine Lehrstelle bot sich ihm, ganz aus der Welt, weit draußen im Meer, auf einer friesischen Insel. Klare-Bel freute sich im Grunde, daß ihre verrückte, glückliche Studentenehe in so stille, geordnete Verhältnisse mündete, aber für Erik that es ihr leid. Denn erstens war er sicherlich zu viel Größerem berufen, als zu diesem abhängigen Stillleben für Weib und Kind, und dann konnte sie ihn sich auch gar nicht anders vorstellen, als im ungeheuren Rahmen einer Weltstadt und im vollen Verkehr mit einer gebildeten, raffinierten Gesellschaft, die ihn fortriß, und die er fortriß. Wie sie ihn zuerst unter den einfachen Menschen des Volkes dastehen sah, kam er ihr vor wie ein verzauberter Prinz. Aber sie kannte ihn und zweifelte nicht: irgendwie werde er auch schon die Leute verzaubern, bis sie seinen prinzlichen Ansprüchen besser entsprächen.

Zu ihrer Verwunderung kam es jedoch ganz anders. Erik lehrte niemand seine Art, wohl aber nahm er die der Leute an. Bald sah man ihn ebenso oft im Schifferwams und in Lederhosen, wie in seiner frühern Kleidung. Seine Umgebung färbte so stark auf ihn

ab, daß er geradezu echt in der Farbe erschien. Aber die Folge war, daß er seine Umgebung beherrschte. Er gab sich nicht, wie Bel gefürchtet, Grübeleien über seine weitausschauenden, ehrgeizigen Wünsche hin, vielleicht war er eine zu aktive Natur dazu.

Was es nur gab, raffte er zusammen, um sich in der Gegenwart voll zu bethätigen, und an die Zukunft, -- an die glaubte er so fest, wie ein Kind an Gott.

Klare-Bel richtete sich ein wenig höher auf in ihren Kissen und stützte den Kopf in die Hand. Weiter als bis hierher dachte sie niemals.

Ein Glanz froher Erinnerung lag auf ihrem Gesicht, der es verjüngte. Die kunstvoll geordneten Locken, die, statt jeder festen Frisur, dies Gesicht umrahmten, trugen noch dieselbe wunderhübsche Goldfarbe wie damals. Nur am Hinterkopf waren sie durch das lange Liegen dünn geworden, ja, dort hatte sich sogar eine ganz kleine, verheimlichte Glatze gebildet.

»Jetzt müssen wir in die Schule wandern, Jonas,« bemerkte Erik und wandte sich vom Fenster.

»Gehst du heute zu den Mädchen, Papa?« fragte der interessiert.

»Ja. Aber deshalb brauchst du mich nicht wieder am Thorweg der Mädchenschule abzuwarten und dort herumzulungern,« versetzte Erik mit einem Seitenblick, der Jonas verlegen machte. Ohne ein Wort zu erwidern, trollte dieser sich aus der Stube.

»Jonas fängt früh an! Er artet dir nach, Erik!« sagte Klare-Bel lächelnd, und als stände es mit ihren Worten in irgend einer Gedankenverbindung, griff sie zwischen allerlei Sachen, die auf einem niedrigen Tischchen neben ihrem Ruhebett standen, einen geöffneten Brief heraus. »Hier liegt noch die Einladung. Wenn du wirklich absagen willst, vergiß es nicht heute in der Stadt, oder gehst du persönlich vor?«

Er streckte die Hand nach dem Brief aus und überflog ihn flüchtig. Es war eine kurze Einladung, unterschrieben: Warwara Michailowna. Erik kniff das Papier zerstreut in kleine Falten und warf es auf den Tisch.

»Ich möchte dich wohl was fragen, Erik.«

»Ja, Bel?«

»Sage mir: gehst du vielleicht nur deshalb nicht mehr in diesen ganzen Kreis, weil sie dir gefährlich geworden ist?«

Er fing an zu lachen.

»Nein, Bel, darüber kannst du ruhig sein.«

»Aber hat sie dich nicht doch einen Augenblick recht stark gefesselt?«

»Das hat sie wohl. Das gelingt doch wohl jeder so reizenden koketten Frau.«

»Junge Witwen hält man immer für kokett. Von Warwara würde ich es nicht denken. Glaubst du das von ihr?«

Er sah seine Frau verwundert an.

»Ja, natürlich. Alle schönen Frauen sind es. Auch ist ihr nicht der geringste Vorwurf daraus zu machen. Das gehört zu ihnen, wie die Schönheit. Das Gegenteil wäre fast stilwidrig. -- Und es ist gut, -- vielleicht ein Grund, warum die Schönheit keinen tiefern Schaden anstiftet. Adieu, Bel: es ist Zeit für uns zum Bahnhof.«

Sie hielt ihm das Gesicht zum Kusse hin. Wie er sich aber zu ihr niederbeugte, umfing sie seinen Hals mit beiden Händen und hielt ihn einen Augenblick, zu ihm aufschauend, fest.

Er hielt geduldig still.

»Du!« sagte sie lachenden Mundes, ließ sich küssen, und ließ ihn los.

Erik und Jonas waren schon fortgegangen, und Gonne räumte eifrig und geräuschvoll in den Stuben auf, als Klare-Bel noch über das letzte Gespräch nachsann. Sie war wahrhaftig nicht grüblerisch und versonnen angelegt; alles andre eher. Aber wenn man ewig so stillliegen mußte, immer auf dem Rücken, und die Augen an der geweißten Zimmerdecke, so geriet man zuletzt auf alles mögliche, und auch auf das Nachdenken. An sich selbst dachte nun Klare-Bel eigentlich nie, stets nur indirekt. Sie kannte im

Grunde nur drei ernstliche, sozusagen hauptsächliche Gedanken, die Sammlung heischten: Erik, Jonas, und die gefürchtete Unordnung im Haushalt. Aber es war merkwürdig, wie viel man aus den dreien machen konnte, wenn man sie geschickt kombinierte. Man hätte meinen können, es seien tausend.

Erik hatte vorhin also gesagt: die Schönheit stifte keinen tiefern Schaden an. Ja, das war gewiß ein rechtes Glück. Denn Erik war sehr empfänglich für die Schönheit. Schon, als sie noch gesund herumging, beunruhigte es sie. Sie selbst war glücklicherweise sehr schön, aber sie war blond, und ihr schien es, als ob die Braunen ihn ebenfalls interessierten. Gewiß hatte er sich ungezähltemal etwas verliebt. Aber nur ein einziges Mal erschrak sie, -- schrak förmlich auf aus aller bisherigen Freude. Während des zweiten Jahres auf der Insel. Da fing er an, sie so viel allein zu lassen; manchmal war es ihr, als ob sie ihm nicht mehr wie sonst genüge. Er wurde auch wortkarger. Und endlich -- ja endlich that sie dann, was er nie im Leben erfahren durfte: sie ging ihm heimlich nach.

An einem weichen, dunkeln Aprilabend war's. Das Meer lag regungslos, und am Himmel stand das erste Frühlingsgewitter. Sie sah ihn aus einem kleinen Hause, hart an der Düne, heraustreten und an ihr vorbei, in Gedanken verloren, heimgehen. In dem Häuschen wohnte die merkwürdigste Frau auf der ganzen Insel. Bei allen stand sie in hohem Ansehen, wegen ihres Verstandes, wegen ihrer Haltung in schweren und wechselvollen Schicksalen, wegen eines seltenen Schatzes von Weisheit und Erfahrung, aus dessen Fülle sie schöpfte, wenn ein feiner, liebevoller Menschenkenner sie zum Sprechen brachte.

Es war Frau Larsen, eine lahme, sechzigjährige Frau.

Seit diesem Abend hegte Klare-Bel ein unbegrenztes Vertrauen zu ihrem Mann. --

Erik verbrachte die ersten Morgenstunden mit Jonas in dessen Gymnasium; gegen Mittag begab er sich in die große Hauptschule für Mädchen, die ziemlich entfernt lag.

Er war in eine vorüberfahrende Pferdebahn eingestiegen, und an einer der letzten Haltestellen sprang ein Kollege zu ihm ein. Dieser sah erhitzt aus, behielt nach der Begrüßung den Hut in den Händen und fächelte sich mit dem Taschentuch.

»Wie geht es, Herr Matthieux?« fragte er Erik, hastig atmend, »hier in der Stadt ist der Mai schon unerträglich, -- wirklich, -- wenigstens im Gehen. Und dabei wagt man nicht, den Sommerüberzieher abzulegen; jeden Augenblick erwartet man wieder von der Newa her einen eisigen Windstoß. Ohne Uebergänge, ohne Normaltemperatur. Ein möderisches Klima.«

Er begleitete seine Worte mit so vielen Gestikulationen, daß man den Eindruck empfing, er werde sich nie im Leben wieder abkühlen. Erik betrachtete mit raschem Blick den ihm gegenübersitzenden, ungefähr gleichaltrigen Mann, auf dessen entblößtes, bereits stark gelichtetes Haupthaar die grelle Maisonne wie spöttisch von draußen hereinsah.

»Ob das meine Zukunft hier ist? -- der Mai unerträglich!« dachte er, und sagte laut: »Ich muß gestehen, ich habe eine Schwäche für diesen russischen Frühling. Er mag unartig sein, vielleicht launischer und gefährlicher wie jeder andre, aber dafür ist er ein Wunder. Er zögert so lange und kommt dann so unerwartet und so unwahrscheinlich schön, daß man seinen Augen nicht traut.«

»Ja, ja. Wenn man Augen dafür behalten kann. Ich reise nach Schulschluß immer nach Deutschland zurück und erhole mich von den russischen Windstößen und Verhältnissen. Ich schreibe an einem Werk, -- immer in den Ferien in Deutschland. ~Das~ ist meine Erholung. Da bleibt für den Sommer wenig übrig. So geht es uns eben allen -- allen, die wir uns geistig überarbeiten müssen.«

Erik schwieg einen Moment, dann erwiderte er, wie wenn er einen stummen Gedanken beende, ruhig: »Ich weiß mich freilich nur sehr zum Teil als ›Geistesarbeiter‹.«

»Ach, Sie meinen doch nicht, weil Sie da drüben, -- weil Sie etwas lange in ländlichen Verhältnissen --? aber ich bitte Sie, bei Ihrem Wissen und Ihrer Begabung! Warum sollten Sie nicht auch noch ein Werk schreiben?«

Erik lachte.

»Nein, so meinte ich es nicht. Nicht daß ich drüben vielleicht ein wenig verbauert sein könnte. Nicht den Mangel an Büchern. Denn wir -- der Lehrer vor allen Dingen, arbeitet doch vorwiegend mit Menschenmaterial. Wir gehören schon einigermaßen außerhalb der Gelehrtenstube, scheint mir. Mitten in das Leben hinein.«

»Hm!« machte der Kollege, »ich finde, an die Menschen kommt man doch nur sehr oberflächlich heran. Es bleibt wirklich nur die Schreibtischarbeit. Aber sagen Sie doch mal: man sprach davon, daß Sie vor ein paar Monaten eine Reihe von Vorträgen haben eröffnen wollen? Was war es damit?«

Eriks Augen verdunkelten sich.

»Nichts war es damit!« sagte er kurz, »man hat mir den Saal verweigert.«

»Sehen Sie, -- sehen Sie! das kommt von Ihrer unbequemen Auffassung des Lehrerberufs außerhalb der Arbeitsstube. Man fürchtet, daß Sie ein wenig lebhaft werden könnten. Wir gehen hier ja eben alle mit gebundenen Händen, -- Sie wissen's doch! Aber mit Einem sollten Sie sich wirklich trösten: es ~gibt~ hier ja gar keine Menschen, unter denen irgend etwas zünden und wirken kann. Es gibt nur das Volk, zu dem wir weder sprechen dürfen noch können, -- und ein Publikum, das sich amüsieren will.«

Er hatte sich in Eifer gesprochen. Erik antwortete nicht. Die Pferdebahn hielt und beide stiegen aus.

»Nun haben Sie noch neue Stunden an der Mädchenschule übernommen!« nahm sein Begleiter das Gespräch wieder auf, und wie er jetzt langsam einherschritt und das Straßenpflaster durch seine Brille fixierte, sah er ebenso schwerfällig und versonnen aus, wie vorhin hastig und zerfahren, »ja, da möchte man Sie am liebsten für alles ausnutzen! Sie hatten diese Klasse ja erst im Herbst anzutreten.«

»Es war aber Not am Mann. Auch wollte ich die Mädchen kennen lernen, Fühlung gewinnen, ehe ich sie im Herbst ganz übernehme.«

»Nun, Sie werden es satt kriegen. Wissen Sie, dieses Geschlecht ist entsetzlich! Und nicht das geringste Talent für Mathematik unter ihnen. Auch nicht das geringste. Rechnen können sie alle nicht.«

»Gott sei Dank!« sagte Erik.

»Nein, nehmen Sie es nicht humoristisch. Als Mädchenlehrer verlernt man das Lachen. Unmöglich gefallen Ihnen die Backfische in Ihrer Klasse?«

»Hübsche Mädels!« entfuhr es Erik beinahe; als er aber die fast bekümmerte Miene seines Begleiters gewahrte, verschluckte er es noch rechtzeitig und erwiderte nur: »Sie bringen doch Anregung, Abwechslung. Sehen Sie, hier in meiner Lederrolle: ein ganzer Stoß Aufsatzhefte. Das kurioseste Zeug. Sie gehen noch auf meinen Vorgänger zurück; ich ließ sie mir nur geben, um mich zu orientieren. Auch habe ich eine wirkliche Merkwürdigkeit darunter gefunden.«

»Da bin ich nicht neugierig!« versicherte der Kollege von der Mathematik und kniff die Augen zu, »wahrhaftig nicht. Aber Sie sind ein beneidenswerter Mensch. Von Ihrem Vorgänger weiß ich, daß diese blauen Aufsatzhefte ihm bisweilen noch des Nachts Alpdrücken verursachten.«

»Das war nur gerechte Strafe!« meinte Erik lachend, während sie einen hohen Thorbogen durchschritten und in das Schulgebäude eintraten, »warum gab er auch Aufsatzthemata, wie zum Beispiel das letzte hier: ›Ueber das Glück‹. Arme Mädels, die da in schönem Deutsch beschreiben sollen, was sie doch noch gar nicht genossen haben.«

Sie blieben vor dem breiten steinernen Treppenhaus stehen, das von der Flurhalle zu den Klassen emporführte.

»Deutsch schreiben lernen könnten sie doch jedenfalls daran, und das ist ja wohl der Zweck,« bemerkte der Kollege steif, denn die letzte Bemerkung hatte ihm höchlich mißfallen, »Ihr Vorgänger hat gewiß an kein Glück gedacht, zu dem man die Schule verlassen haben muß. -- Aber hier trennen sich wohl unsre Wege. Ich meine: wörtlich.«

»Also auf Wiedersehen!«

»Wünsche beste ›Anregung‹.«

Erik stieg hinauf und ging durch den hohen Hallengang, an welchem die Klassenzimmer lagen. Er öffnete eines derselben und blickte auf seine Uhr. Noch war die Frühstückspause nicht vorüber. Die meisten Mädchen hatte der Maisonnenschein in den großen Schulhof gelockt; man konnte sie durch das offene Fenster unten paarweise herumgehen und spielen sehen. Dicht unter dem Fenster, an das er sich setzte, stand der Brunnen mit einer Holzbank; dort machte es sich eine Gruppe halberwachsener Mädchen bequem, -- das Kichern und Schwatzen drang deutlich bis zu Erik herauf.

In den umliegenden Klassen und auf dem Gang war es ganz still; selten nur klappte eine Thür oder wurde ein Ruf laut. Aus den zur Hälfte niedergelassenen Fensterrouleaux brütete die Sonne und einzelne Brummfliegen surrten um ein paar Brotkrumen aus den staubigen Pulten.

Erik hatte die blauen Hefte hervorgezogen und blätterte darin, wobei er jedoch von Zeit zu Zeit einen Seufzer ausstieß. Im Grunde waren dies wirklich recht langweilige Schulhefte. Solch ein Backfisch ist interessant, ohne Zweifel, er ist als Mensch, als Weib, als Backfisch interessant, und eine Welt für sich; aber von alledem kommt in den Schulaufsatz nichts hinein. Kein Wunder! Ist es nicht schließlich ebenso mit allen geschriebenen Büchern der Welt? Ist nicht der kleinste Ausschnitt des wirklichen Lebens tausendmal reicher, aufschlußgebender?

Er stand auf und warf einen Blick auf die lachende, schwatzende Mädchengruppe am Brunnen. Diejenigen, welche er von seinem Standort sehen konnte, gehörten sicher seiner neuen Klasse an, hatten also die langweiligen Aufsätze auf dem Gewissen. Er verzieh sie ihnen, während er sie so anblickte, -- diese frischen Geschöpfe, die noch das Vorrecht besaßen, ohne Schönheit schön zu sein. Es waren ganz bestimmte Typen unter ihnen leicht zu unterscheiden, obgleich sie verschiedenen Nationalitäten angehörten. Drei Sprachen schwirrten durcheinander. Er unterschied am deutlichsten den mehr hausfraulichen und den mehr weltlichen Typus. Beide besaßen etwas Anziehendes, -- sowohl dieser schelmische Blick, der so weiblich ahnungsvoll unter den sorgfältig gekrausten Stirnlöckchen hervorlugte, als auch der sanfte, sittsam stille Augenaufschlag unter dem Madonnenscheitel. Das eigentlich kindliche Genre war unter diesen Backfischen fast gar nicht mehr vertreten. Und vielleicht deshalb auch so wenig Urtypisches im ganzen, wenig Individuelles, -- man konnte sie schon klassifizieren, sie waren schon fest geprägt durch ihre Umgebung, in der sie erzogen wurden, in der es aber keine geborenen Erzieher und Menschenfischer nach Eriks Ideal gab, sondern nur gewöhnliche Amts- und Standespersonen.

Unwillkürlich suchte seine Hand zwischen den Heften, als wünsche er sich selbst Lügen zu strafen. Ja, hier stand die »Merkwürdigkeit« unter den Aufsätzen, -- etwas höchst Individuelles jedenfalls.

Anstatt des vorgeschriebenen Titels »Ueber das Glück« trug er die Ueberschrift »Seligkeit!« -- und wie ein Sehnen und Jauchzen klang dem Lesenden etwas von dieser Ueberschrift aus jeder Zeile entgegen. Er war nicht in vernünftiger, oder doch wenigstens korrigierbarer Prosa geschrieben, sondern in Versen, -- in gänzlich unkorrigierbaren und wilden Versen, in denen die Sprache Reißaus genommen hatte. Trotzdem wirkten diese Verse, so fehlerhaft sie hingeschrieben waren. Oder vielmehr: hingeträumt. Denn im Grunde glich dieses einem unklaren Traum, einem bloßen Gedankenstammeln, einem Sichauflehnen gegen Wort und Logik, aber es steckte eine mit sich fortreißende Gefühlsmacht darin. Man wurde im höchsten Grade ungeduldig bei der Lektüre, aber man wurde auch vom ungeduldig drängenden Wunsche überfallen, dem, der hier träumte und stammelte, mit Gewalt die Zunge zu lösen, daß er Aufschluß gäbe über seine Seele. Solche Verse mochte die heilige Therese als Kind gedichtet haben, ehe sie ihre Visionen aus Gott bezog, dachte Erik. Welche von denen im Hof mochte das sein?

Einzelne Worte tönten laut und erregt zu ihm herauf und rissen ihn aus dem Lesen auf. Er hörte eine von den Mädchenstimmen mit größter Energie sagen: »Er ~muß~ unglücklich sein. Ich will es so. So unglücklich wie nur möglich. Sonst thue ich es nicht.«

»Nein, nein, dagegen bin ich ganz!« rief eine andre in mitleidigem Ton.

»O, ich wäre schon dafür,« suchte eine dritte zu vermitteln, »wenn es nur für eine Weile ist. Denn später, da heiratet sie ihn ja dafür.«

»Heiratet?« fragte die erste Stimme erstaunt, »nein, ich denke nicht daran! Er ist und bleibt unglücklich, sage ich euch. Ein für allemal. Aber heiraten werde ich ihn nicht.«

Erik fiel das Heft aus der Hand. Er stützte sich auf das Fensterbrett und sah vorsichtig hinab. Er hätte gern gewußt, wie das grausame Geschöpf aussah, das den Unglücklichen lebenslang gemartert wissen wollte und ihn nicht einmal heiratete.

Aber sie saß offenbar dicht an der Hausmauer und war von den andern so umstellt, daß Erik sich nicht tiefer hinabbeugen konnte, ohne von unten her gesehen zu werden. Er erblickte nur zwei schmale, weit vorgestreckte Füße in ausgeschnittenen Schuhen und dunkeln Strümpfen.

Jetzt zwitscherten alle so durcheinander, daß man nichts verstand.

Dann sagte ein bildhübscher, dunkelhaariger Backfisch, während er herzhaft in einen Apfel hineinbiß: »Ich finde es wirklich komisch von dir. Denn wozu haben wir ihn sonst mit so vielen und besondern Eigenschaften ausgestopft, wenn du ihn doch nicht

nimmst? Er hat doch das Allerbeste abbekommen. Wenn er nur edel und unglücklich sein soll, so hätte er auch gewöhnlicher bleiben können, -- meint ihr nicht?«

»Laß sie doch, Wjera, du sollst sehen, sie hat im stillen schon wieder etwas Neues vor, -- vielleicht was viel Schöneres,« meinte ein kleines, blondes Mädchen in zierlich gestickter Latzschürze, »und wenn ihr sie nicht in Ruhe laßt, so sagt sie es uns am Ende nicht.«

»Hast du was? Hast du was? Ist es schön?« schrieen sie erwartungsvoll.

»Es ist nichts für euch! Aber von allen die allerschönste Märchengeschichte!« erklärte die Angeredete an der Hausmauer, »kennt ihr die Verse von Uhland?« Und sie begann mit einer weichen Stimme zu deklamieren:

»In Liebesarmen ruht ihr trunken, Des Lebens Früchte winken euch; Ein Blick nur ist auf mich gesunken, Doch bin ich vor euch allen reich.

Das Glück der Erbe miss' ich gerne, Und blick', ein Märtyrer, hinan, Denn über mir, in goldner Ferne, Hat sich der Himmel aufgethan.«

Sie lauschten mit ganz feierlichen Gesichtern, bis die letzten Worte, gedämpft, in einer Art von schwärmerischer Andacht, verklangen.

»Huh!« sagte die hübsche dunkle Wjera, ordentlich ergriffen, und eine zweite fügte besiegt hinzu: »Ja, dann freilich --«

Aber die, welche deklamiert hatte, lachte nur. Sie lachte so von innen heraus, so frisch und mit so überzeugenden Trillern in der Kehle, daß Erik oben an seinem Fenster beinahe angefangen hätte, mitzulachen, und sich plötzlich mit ihr wie im Bunde fühlte. Auch von den Mädchen begannen einige zu kichern. Aber die meisten verstimmte es.

»Du hast gar keinen Lebensernst!« sagte die Erste der Klasse strafend, eine andre aber behauptete sogar: »Sie hat kein Herz. Sie verlacht ihre eigene Sache, und uns mit.«

Nur das blonde niedliche Mädchen schien sich zärtlich an die Lachende zu schmiegen und erinnerte sie: »Du hast doch versprochen, uns den ›Unglücklichen‹ endlich zu zeigen. Willst du es heute auf dem Heimweg thun?«

»Ja, das will ich. Denn ich will ihn euch überlassen. Macht ihn so glücklich, als ihr wollt.«

»Also denkst du an einen andern?«

Die Glocke, die zum Klassenbeginn läutete, unterbrach das Geplauder in diesem kritischen Augenblick. Arm in Arm schlenderten sie gemächlich ins Schulgebäude hinein. Die schmalen Füße aber lagen noch ausgestreckt in der Sonne.

»Jetzt muß ich sie sehen können,« dachte Erik und beugte sich mit ernstem Gesicht vor. Das Gespräch der Mädchen hatte ihn ganz betroffen gemacht.

Und er sah sie.

Gegen die grau getünchte Hausmauer nachlässig zurückgelehnt, die Arme hoch über dem Kopf verschränkt, saß sie auf einem umgestülpten Regenfaß, das, in diesem beliebten Brunnenwinkel, gelegentlich als Sitzbank benutzt wurde. Sie trug das entschieden aschblonde, glanzlose Haar offen, so daß es, weich und lockig, in einiger Verwirrung, ihr über Brust und Schultern fiel. Das tiefrote Bändchen, welches es wohl am Hinterkopf zusammenhalten sollte, war hinabgeglitten und bewegte sich leise im Luftzug. Es war der einzige bunte Punkt und Schmuck am Bilde. Denn die ganze schmächtige Gestalt steckte in einem losen, graublauen Gewande, das keinerlei Aehnlichkeit mit den hübsch gearbeiteten Kleidern, Miedern, Schleifen und Schürzen der andern aufwies. Ueber den schmalen Hüften durch einen einfachen Ledergürtel kittelartig geschlossen, ließ es zwischen den weichen Falten kaum den zarten Ansatz der Brust erkennen und verlieh dem Mädchen etwas sonderbar Knabenhaftes. Aber darüber erhob sich ein unregelmäßiges Gesichtchen, das geradezu ansteckend in seinem ausgelassenen Uebermut wirkte. Wie sie so dasaß, den Oberkörper zurückgezogen, die ziemlich dunkeln Augen leuchtend erhoben, die Lippen, wie in beginnendem Gelächter oder wie in verlangendem Durst, halb geöffnet, so daß unter der zu kurzen und stark geschweiften Oberlippe die weißen Zähne hervorschauten, -- da machte sie den Eindruck, als bäume sie sich auf in überschäumender Lebenslust, bereit, jeden Augenblick jauchzend über alle Stränge zu schlagen, -- fast unwillkürlich dachte man sich einen Thyrsusstab in die

hinaufgestreckten verschlungenen Hände, -- und der Bacchusknabe war fertig.

Als sie sich rasch und unvermittelt aufrichtete und ins Haus sprang, erhob sich Erik aus seiner vorgebeugten Stellung am Fenster und raffte hastig seine Hefte zusammen. Während er den Weg in seine Klasse antrat, kam ihm ein Lachen über seine eigene Verdutztheit. Zwei Lämmer in seiner Herde gehörten jedenfalls nicht dem langweiligen Durchschnitt an: die heilige Therese, und dann dieser arge Schlingel und Taugenichts.

Im Hallengang war es inzwischen von allen Seiten, in allen Ecken lebendig geworden, und einige Minuten lang schwirrte es dort durcheinander gleich einem Mückenschwarm in der Maisonne. Dann schwächte der Lärm sich ab, die Klassenthüren fielen ins Schloß; hie und da eilte noch ein Nachzügler an seinen Platz; einzelne Lehrer, sämtlich in ihrem dunkelblauen Frack, der an diesen Schulen vorgeschriebenen Uniform, schritten grüßend aneinander vorüber oder blieben, ein paar Worte wechselnd, im Gange stehen. In Eriks Klasse war alles schon mäuschenstill und in schönster Ordnung beisammen, als er mit belebtem Gesichtsausdruck hereintrat. Einen Augenblick lang ließ er, auf dem Katheder stehend, seinen Blick über die blonden und braunen Mädchenköpfe schweifen, die fast alle mit lebhaften und aufmerksamen Augen zu ihm ausschauten. Obgleich er erst zum zweitenmal aus diesem Platz und seinem jungen Auditorium gegenüberstand, fühlte er doch schon sehr deutlich die Stimmung der Sympathie, die ihm aus allen diesen Augen entgegenleuchtete. Er verdankte sie seinem eigenen Entgegenkommen. Denn die da merkten recht wohl das thatsächliche Interesse, das er ihnen als Lehrer zubrachte, -- den Blonden wie den Braunen, den Klugen wie den Dummen, den Willigen wie den Widerspenstigen. Welche Fehler er auch besitzen mochte, einen wenigstens besaß er nicht: seinen Unterricht als eine leblose Pflichtmaschine zu absolvieren.

Erik schob die blauen Hefte an den Rand des Kathederpultes und sagte, sich niedersetzend: »Die Hefte können wieder verteilt werden. Sie sind zum größern Teil recht bedauerlichen Inhalts. Hoffentlich lautet die Fortsetzung viel besser. In Bezug auf einen Aufsatz darin möchte ich aber eine Erkundigung einziehen.«

Er schlug den Deckel des obersten Heftes zurück und fragte, den Namen ablesend: »Wer ist Ruth Delorme?«

Die Aufgerufene schien diese Frage erwartet zu haben; sie hatte sich bereits erhoben, ehe ihr Name von seinen Lippen fiel.

Er richtete einen bestürtzten Blick auf sie. Es war der Bacchusknabe aus dem Schulhof.

Jetzt freilich machte sie den kuriosen Eindruck nicht mehr so ganz. Das ordentlich zusammengenommene Haar und der »Klassenernst« aus ihrem Gesicht störte ihn, -- vielleicht auch, daß sie die Augen niedergeschlagen hatte. Am liebsten wäre Erik ihr mit der Hand über das Gesicht gefahren, wie um eine Maske abzustreifen, damit er darunter die wirkliche Ruth zu sehen bekäme. Aber das wäre dann der mutwillige, lachende Junge von vorhin gewesen, -- und das deckte sich so wenig mit der Vorstellung, die der Aufsatz von ihr weckte. Das wunderliche Geschwätz der Mädchen am Brunnen fiel ihm ein.

»Unmöglich!« entfuhr es ihm.

Sie sah verwundert auf.

»Doch!« sagte sie.

»Das kann sie! sie kann Verse machen!« riefen einige Stimmen. Man konnte es ihnen anhören, wie stolz sie auf diese Schwarzkunst waren, und wie interessant sie das unerwartete Intermezzo fanden.

»Verse, -- das ist ja möglich,« gab Erik zurück, »auch sind sie keineswegs schön. Ganz im Gegenteil. Aber ein Schulmädchen --«

Er brach etwas verlegen ab und ärgerte sich. Die Bemerkung war auch gar zu einfältig. Schulmädchen waren sie ja alle, und ~eine~ von ihnen mußte es doch gewesen sein. Mußte? Da kam ihm ein Gedanke: vielleicht ist es gar kein selbständiger Aufsatz?

Er blätterte im Heft zurück. »Es ist noch ein früherer Aufsatz darin. Etwas Literarhistorisches. Der fällt stark dagegen ab. Lauter mühsam nachgezogene Linien -- und falsche Linien. Es geht die Sage, daß bei den Aufsätzen nicht immer fremde Hilfe verschmäht wird. Sollte das nicht die Lösung des Rätsels sein?«

Während er aber noch sprach, war er schon überzeugt, daß er sich irrte, und daß sie sogleich auftrotzen und mit beleidigtem Stolz behaupten werde, ihr habe niemand geholfen.

Jetzt schüttelte sie auch wirklich den Kopf und sagte: »Mir hilft niemand.«

Aber wieder schaute er betroffen auf. Wie klang das! Gerade so, als habe sie unter Thränen gesagt: »Ich bin ja so mutterseelenallein!« Ein stiller Ton war darin, der ihn rührte, -- etwas so ganz Neues, Unerwartetes, das er wieder mit dem übrigen nicht zusammenreimen konnte.

Es litt ihn plötzlich nicht mehr auf dem Katheder, in der ruhigen Haltung des Lehrers. Ein zwingendes Gefühl von Interesse fand gleichsam seinen Ausdruck darin, daß er herabstieg und zu ihr hintrat an die Bank, in die Mitte der übrigen.

Als er dicht vor ihr stand, ward er sich einer Uebereilung bewußt und kehrte, wenn nicht zum Platz, so doch zur Rolle des Lehrers zurück.

»In der Aenderung des Titels und der Anwendung von Versen liegt eine auffallende Abweichung vom Vorgeschriebenen; hier galt wohl eine Ausnahme, die mein Vorgänger machte?« fragte er.

»Er zog sie vor! sie durfte thun, was sie wollte!« schrieen einige.

»Sie gehört nicht mehr zur Schule! Sie kommt nur zu einigen Stunden!« riefen andre.

»Ich gehe bald fort,« sagte Ruth.

»Fort? Vom Ort?« fragte er, und ein brennendes Bedauern überfiel ihn.

Sie hob die Augen.

»Nein. Nur aus den Stunden.«

Wie beider Blicke sich trafen, sah er ihr Gesicht aufleuchten. Nicht nur die Augen thaten's, das Leuchten ging über Stirn und Augen, wie ein Lächeln, obschon sie ernst blieb. Der »Klassenausdruck« fiel von ihren Zügen wie ein vorgehaltener Schleier.

Er gab ihr einen Wink, daß sie sich setzen möge.

»Das ist sehr schade,« meinte er dann, ein paarmal auf und ab gehend, und es war ihm selbst nicht klar, für wen es eigentlich schade sei, ob für den Lehrer, oder für die Schülerin, oder für beide. Doch setzte er rasch hinzu: »Es ist zu früh. Ein Zeichen von Reife ist der Aufsatz nicht.«

Dann richtete er, mit dem Aufnehmen des Unterrichts, keine Bemerkung mehr an sie, vermied es auch während der Stunde ihren Namen aufzurufen, obgleich es ihn beschäftigte, daß sie fortgehen wollte. Aber er begriff, daß dieses lebhafte Interesse an einem merkwürdigen Kinde, wenn es auch ausschließlich den Erzieher in ihm reizte, von ihm selbst erst völlig beherrscht werden und in ihm selbst sich erst völlig geklärt haben mußte, ehe daran zu denken war, ihr vor einigen Dutzend neugieriger Mädchenaugen nachzugeben. Er kannte sehr wohl die üblichen Schwärmereien für den Lehrer, zweifelte auch nicht daran, daß auch er bereits Gegenstand solcher Schwärmereien sei, hielt aber doch möglichst daran fest, daß sein eigenes Benehmen ihn nicht verriete, wenn einmal eine kleine Schülerin Eindruck auf ihn machte, -- was doch unvermeidlich geschah unter Menschen von Fleisch und Blut.

Ruth saß still auf ihrem Platz und folgte seinen Worten und Bemerkungen mit verträumten Augen. Sie war eine ziemlich zerstreute Schülerin, und so nahm sie auch jetzt im Grunde nichts von dem auf, was er vortrug, sondern merkte sich nur die Art, ~wie~ er vortrug, und die ihm eigentümliche Gebärde der Hand dabei. Daß er schmale, nervige Hände von edler Form besaß, daß sie aber leicht gebräunt waren, wie bei einem, der sich viel der Luft und Sonne ausgesetzt hat, merkte sie, -- und es kam ihr wie ein Widerspruch vor, der sie beschäftigte. Die breite, etwas steile Linie seiner Schultern prägte sich ihr ein, wie ein Bild, und dann, daß ihm das Haar beim Sprechen in einem straffen, kleinen Büschel in die Stirn fiel, und er es stets mit einem kurzen Ruck zurückwarf, wobei der Kopf ein wenig hochmütig oben blieb. Es war kurzgehaltenes, schlichtes, dichtes Haar, und es ärgerte sie förmlich, daß es sich nirgends ein klein bißchen locken wollte, -- nur ein bißchen; in Gedanken ließ sie ihm lange Locken wachsen; die sahen aber drollig aus, und so schnitt sie sie ihm wieder ab. Darüber mußte sie lachen; sie hätte fast laut aufgelacht, und der Sicherheit halber stützte sie den Mund auf die Hände.

Aber bei alledem sah sie nicht aus, als ob sie sich in losem Mutwillen mit solchen Aeußerlichkeiten beschäftige, sondern als sinne sie angestrengt und ganz in sich vertieft einem schwierigen Problem nach. So hatte sie schon neulich, in seiner ersten Stunde, dagesessen, von ihm unbemerkt.

Ruth machte noch immer dasselbe verträumte, nachdenkliche Gesicht, als nach Beendigung des Unterrichts ein ganzer Schwarm von Mädchen sich zum Heimgehen um sie drängte. Sie hatte diesen Augenblick kaum erwarten können, denn nun sollte Ruth

ihnen ja den »Unglücklichen« zeigen, der aller Phantasie beherrschte. Arm in Arm, hintereinander, und mit den Ranzen schlenkernd, gingen sie lachend und schwatzend die Straße hinab und bogen in den Newsky Prospekt ein, Ruth voraus und ohne auf sie zu achten. Einige sahen sich vorsichtig um, ob ihnen auch niemand folge, auf den Wegen, die Ruth sie führen sollte; aber die Straße war ziemlich menschenleer, nur ein paar Dienstmädchen, die den Verwöhntesten den Schulsack trugen, folgten in bescheidener Entfernung, und hinter diesen sah man Erik herankommen.

»Eigentlich ist die Ruth doch eine Glückliche!« sagte die hübsche Wjera zu ihrer Nachbarin, »daß sie solche Geschichten treiben kann. Ich glaube, ihre Verwandten kümmern sich gar nicht darum. Ja, es ist ganz anders, wenn man noch Eltern hat.«

»Pfui, schäme dich!« empörte sich das Mädchen, das neben ihr ging, und stieß sie mit der Frühstücksbüchse in die Seite, »es ist doch ein schreckliches Unglück, seine Eltern so früh zu verlieren. Die arme Ruth! Denke nur, wo sie von ganz klein auf schon alles gewesen ist, -- in Belgien und Deutschland, und immer unter fast Fremden.«

»Ja, da kommt man eben auch weit herum,« beharrte der gemütlose Backfisch, »sogar in einer Schweizer Pension ist sie gewesen. Und gerade da möchte ich so gern hin.«

»Sogar in einem Glaspalast hat sie einmal gewohnt,« behauptete eine von ihnen etwas unsicher.

Ein schallendes Gelächter erhob sich.

»Ja, im Traum! Das ist doch nur ein Märchen, das sie erzählt hat. Höre nur, Ruth, das hält sie für Wirklichkeit.«

»Da kommt er!« sagte Ruth mit einemmal.

Das Wort fiel wie ein Schrotkorn in einen Haufen lärmender Spatzen. Im ersten Augenblick stoben sie fast auseinander, aber dann sammelten sie sich wieder, räusperten sich, zupften an ihren Kleidern, reckten die Hälse, und die meisten von ihnen wurden rot.

»Hier, der Blonde.«

»Nein! Der Herr im Cylinderhut.«

Es war keiner von beiden. Ruth blickte ernsthaft geradeaus, und einem Herrn ins Gesicht, der auf sie zuschritt. Ein junger, brünetter Mann, im hellen Sommerüberzieher, mit etwas verlebten Zügen, einem kleinen Schnurrbart und mandelförmigen Augen.

Er schien wie geschaffen zum Helden der Tragödie, -- darüber waren alle einig. Aber während sie ihn noch anstarrten, wie ein Meerwunder, passierte vor ihren Augen das Ungeheuerliche, woran sie eigentlich doch nicht im Ernst geglaubt hatten: Ruth grüßte ihn; ganz ernsthaft grüßte sie ihn, ohne eine Miene zu verziehen, aber doch so wie einen alten Bekannten.

Ein halbes Lächeln glitt über sein Gesicht; er hatte sie fest fixiert, jetzt griff er eilig an den kleinen runden Filzhut und grüßte wieder. Ziemlich vertraulich that er das.

Die hübsche Wjera schrie fast aus vor Ueberraschung und Vergnügen; sie war feuerrot geworden, und um ihrer Herzensbewegung Herr zu werden, mußte sie ihre Begleiterin unwillkürlich in den Arm kneifen. Ein paar von den andern aber hielten sich von der Gruppe etwas getrennt, sie genierten sich sichtlich, gingen verlegen neben dem Trottoir auf dem Straßendamm einher und schlugen die Augen nieder. Doch fand der heldenhafte Unbekannte noch eine beträchtliche Anzahl unter ihnen, die mit Augen und Mienen das Spiel fortsetzten. Während er mit ganz verlangsamten Schritten an ihnen vorüberging, flogen Blicke und Lächeln zu ihm hinüber, empfingen deutliche Antwort und wurden wiederholt. Ein paar Köpfe drehten sich auch noch nach ihm um, und auch er wurde nicht müde, zurückzusehen.

»Nein! Das ist aber zu arg!« brach eine von den Sittsamen auf dem Straßendamm los, »es ist geradezu sündhaft!«

»Ach, du liebe Tugend! Wir sind es ja gar nicht gewesen, die angefangen haben. Ruth hat es gethan. ~Sie~ hat ihn gegrüßt. Wenn sie jetzt auch so gleichgültig drauf los geht, als ginge es ~sie~ nichts an.«

»Ja, was schadet es denn auch?« verteidigten mehrere ihr Benehmen etwas betreten.
